INFLUENZO-PNEUMOCOCCAL AND INFLUENZO-STREPTOCOCCAL SEPTICÆMIA:

EPIDEMIC INFLUENZAL "PNEUMONIA" OF HIGHLY
FATAL TYPE AND ITS RELATION TO
"PURULENT BRONCHITIS."

SHOT COMMAND; PHYSICIAN TO GUY'S HOSPITAL.

(With Coloured Plates.)

INTRODUCTION.

WHEN we published a paper upon "Purulent Bronchitis, its Influenzal and Pneumococcal Bacteriology," in conjunction with Dr. John Eyre, in THE LANCET of Sept. 8th, 1917, we were particularly desirous of drawing attention to the anomalous character of many of the cases of "pneumonia" that we had encountered in the Aldershot Command during the years 1915, 1916, and 1917, and because we felt that "pneumonia," in the sense of true croupous lobar pneumonia, was a misnomer in connexion with many of them. The "purulent bronchitis" type of certain of these anomalous cases that had up to that time been returned generally as "pneumonia" is now familiar to most Army physicians, but at the time of our own investigations, and those of Hammond, Rolland, and Shore,¹ the bacteriological nature of this severe purulent bronchitis, with its remarkable heliotrope cyanosis, abundant sputum, and high mortality, was not, we think, recognised generally.

Though it was occurring in the form of multiple small epidemics in France and in England, there was then no generalised epidemic to lead to the suspicion that it had an influenzal basis; and it was as the result of extended bacteriological research, *intra vitam* and *post mortem*, and not from the observation of clinical phenomena, that its causation was found to be primarily influenzal, with symbiotic or secondary invasion of the respiratory tract and circulating blood by either pneumococci or streptococci, the virulence of which, it seemed, had been so exalted by the coexistence of influenza bacilli that they caused death in a high percentage of cases by reason of a veritable pneumococcal or streptococcal septicæmia.

The condition, though labelled "purulent bronchitis" on account of the dominating characteristics—viz., the severity of the chest symptoms, and particularly the appearance and quantity of the sputum—seemed to us, even at that time, to be an *influenzo-pneumococcal* or an *influenzo-streptococcal* septicæmia with a prominence of lung symptoms rather than a purely pulmonary disease. The question of the relationship of the streptococcal to the pneumococcal cases is elaborated later in this paper, but it may at once be stated that there is now much evidence in favour of the view that the streptococcal organisms described in certain epidemics may be really pneumococci growing temporarily in streptococcal form.

Since 1916, when the "purulent bronchitis" cases were differentiated more or less clearly from amongst the big group of anomalous "pneumonia" cases, we have had ample opportunities, more especially during the recent epidemics, for broadening and extending our views. We believe now that the "purulent bronchitis" type is merely one of many; that "*influenzo-pneumococcal septicæmia*" is responsible for much, if not all, of the fatal "*influenzal pneumonia*" which

is at the present moment (October, 1918) causing sickness and death, not only amongst troops in camps, but also, and to an almost greater extent, amongst the civil population, affecting Africa, America, and Asia as well as Europe, leaving few towns untouched in any country in which it has obtained a start, and spreading virulently amongst those who are aggregated closely together—for instance, when it breaks out on board ships on the high seas.

It is for others to deal with its epidemiology; we would confine our remarks to the clinical, bacteriological, and post-mortem aspects of the disease as we have seen it amongst troops at Aldershot and elsewhere. But once again, and even at the risk of becoming monotonously insistent, we would emphasise our view that in essentials the *influenzo-pneumococcal* "purulent bronchitis" that we and others described in 1916 and 1917 is fundamentally the same condition as the "*influenzal pneumonia*" of this present pandemic, and that it is only a matter of degree whether there is "purulent bronchitis," "capillary bronchitis," "broncho-pneumonia"—disseminated in some cases, lobar in distribution in others, multiple abscesses in the lungs, or even gangrene of the lungs. Few, if any, of the cases are true lobar pneumonia, and death seems due to an extreme toxæmia or septicæmia rather than to the extent of the lung lesion. In other words, the extent of pulmonary involvement is of comparatively little importance and bears no relation to the virulence of the essential septicæmic conditions.

Statistics: Incidence.—Owing to the extreme pressure of work, the overtaxed state of the medical staff, the variability of nomenclature in official returns, and other similar causes, it has been impossible to keep detailed records of all the cases encountered. In the aggregate we have seen several thousands, of which well over two thousand have been "pneumonic"; and have examined over four hundred autopsies. So variable, however, is the severity of the influenza itself in different units or hospitals at the same time, and so greatly does the mortality vary in troops from different countries that we make no attempt to give statistical details, beyond indicating that our experience is based on thousands of cases and not merely on hundreds.

Pneumonia incidence in the influenza cases.—Of the total number of cases seen in Aldershot and elsewhere during the last few weeks, the majority have been straightforward influenza. Roughly speaking, we may say that out of 1000 cases of "influenza" upwards of 800 have taken an ordinary simple uncomplicated course with fairly speedy recovery and without sequelæ. The remaining 200 have become more or less pulmonary—of these perhaps 80 being of moderate severity, the remaining 120 have been desperately ill; and of this last-named category somewhere between 60 and 80 have died.

These figures do not hold good throughout, for the lung complications and mortality have struck us as being very much higher amongst soldiers who have recently joined up than amongst those of longer service. They have been higher still amongst certain troops from overseas—South Africans, United States troops, and New Zealanders, *par excellence*—than amongst others.

The "pneumonic" cases and the mortality amongst them have also seemed to form a much higher percentage of the total "influenza" cases in a unit in which the epidemic has just started than after the epidemic has prevailed in the unit for a week or two. It is when the epidemic is in its earlier days that it is apt to spread like wild-fire and cause the greatest damage and the highest death-rate; although, so far as a whole Command is concerned, the daily sick and the daily mortality may continue at a high level for a longer time than it does in a single unit owing to the fact that the epidemic, whilst subsiding in one unit, tends to spread and break out in fresh units one after another.

THE SYMPTOMS.

(a) In the Straightforward Influenza Cases.

The symptoms in the straightforward influenza cases are precisely similar to those of ordinary influenza as it occurs in other places and at other times.

The onset has generally been sudden and acute. There have, of course, been many quite mild cases, but again and again a perfectly healthy man may be taken ill in the street or on duty with a sense of general malaise; he feels chilly, suffers from aches in his back, limbs, and head, and rapidly develops such a sense of prostration that wherever he is he has to lie down. He may rally sufficiently to be able to get himself back to his quarters with some difficulty, or he may be so bad that he has to be carried.

He gets to bed and is only too glad to stay there. He is nauseated at the sight of food and "feels rotten." Though drowsy, often he cannot sleep. His temperature is raised, generally as high as 104° F. or more. The pulse is full and firm, its rate is as rule not raised proportionately to his temperature, and his respiration-rate is between 18 and 30. Many cases have red injected palate and anterior fauces and complain of sore throat, but many have no such complaint, and on examination of the chest physical signs are absent. The tongue is almost invariably coated with a thick fur, superficially yellowish-brown at the back and on the dorsum, pale yellowish-white beneath the darker surface, and often with no fur on the margins and tip.

Eptistaxis, sometimes of almost alarming degree, has been an unusually common phenomenon in this epidemic, sometimes at the

¹ THE LANCET, July 14th, 1917, p. 41.

beginning, more often after the patient has already gone to bed, and in quite a number of cases the hearing has become much impaired, a few cases having become temporarily stone deaf. Quinine prophylaxis may be a factor in this, but that there is middle-ear catarrh in at least some of the cases has been shown by subsequent ear discharge, and in one or two cases by considerable bleeding from each ear.

Vomiting has not been usual, but it has occurred often enough to attract attention. *Diarrhoea* to the extent of six or seven loose motions on the first day or two has been rather less uncommon.

Abdominal pain has not been a pronounced feature although occasionally it has existed of sufficiently severe character to lead to a provisional diagnosis of appendicitis, and even to some solicitude as to differentiation from an acute abdominal condition urgently needing operation.

In the earlier part of the recent epidemic *laryngeal symptoms* were not common to the same extent as in a curious outbreak of supposed "Influenza" last year (not the "June, 1918," epidemic), but latterly quite a number of the men have been husky-voiced or even unable to phonate at all. These cases have not necessarily passed on to the "pneumonic" type.

The temperature has remained raised a variable number of days. (See Charts.)

Sometimes it fell suddenly as early as the second day, sometimes ending almost by crisis on the third, fourth, or fifth days, sometimes coming down more gradually to reach normal by lysis between the third and the fourteenth day of the attack. Speaking generally, the duration of the pyrexia has been far longer in the recent pandemic than in the cases encountered in June, and the subsequent prostration appears to be proportionately greater.

As long as the temperature has been up to anything like 101° the patient has continued to feel "rotten." With the fall of temperature rapid improvement sets in; the tongue cleans, the patient feels altogether better, begins to take his food with avidity, and convalesces in the ordinary way. Delayed convalescence has occurred either in those who have deferred taking to bed at the beginning, or, more usually, in those who, for duty's sake, have felt obliged to get up and work again before the acute stage of the disease has fully passed.

(b) Symptoms in the "Pneumonic" Cases.

The "pneumonic" or "bronchitic" complications, so much dreaded just now, come on at no fixed or definite period of the influenza attack.

Frequently there is no distinct influenzal period at all, the case being then very similar to one of ordinary lobar pneumonia in the first day or two. Numbers of such cases have been diagnosed as true lobar pneumonia by those who are unfamiliar with the post-mortem findings, and it is remarkable how difficult it is to persuade those who have not seen such cases before that they are not dealing with ordinary pneumonia.

More often the patient has been ill for a day or two with simple influenza, often apparently not at all severe and indistinguishable from the general run of simple influenza cases, before acute or even fulminating pulmonary complications set in, and they may die so rapidly and with so little actual consolidation that it is clearly not the "pneumonia" but something more generalised, a veritable septicæmia, which kills them.

In a third type of case the "influenza" has nearly run its course, and the temperature may have returned to normal or nearly so for a day, or even several days, before it rises again with the onset of "pneumonic" complications.

All three types have been met with in abundance; the commonest is that in which the case has seemed to be one of simple "influenza," for one, two, or three days before it passes on into the much more serious phase of lung and general systemic complication.

There may or may not be a definite rigor; the temperature, already high, may or may not rise further. (See Charts.)

The patient complains in some way of his chest; he coughs with short dry hacking to begin with; the question of his sputum is discussed below. He often complains of pain in one or other side of his chest or in both sides, either in the region of the anterior axillary line about the level of the sixth and seventh ribs, or posteriorly at one or other base, or all over, or down the front of the manubrium sterni "as though he is all raw inside there."

Sometimes the skin is hot, dry, and pungent as in lobar pneumonia, occasionally a scarlatiniform rash of transient duration may be noted, but, on the other hand, it may be covered with profuse clammy sweat, the latter often leading to widespread sweat vesicles (sudamina and miliaria).

The breathing becomes rapid (often 30 per minute or thereabouts, but not seldom 40, 50, or even 60 per minute). The pulse-rate rises, but it is nearly always no faster than corresponds with the pyrexia, and often it is relatively infrequent except at the very end. There is no orthopnea, and although there is rapid breathing there is no dyspnoea.

The facies is at first flushed and red, but in bad cases it speedily becomes less and less of a purely red tint and assumes more and more of a lavender, heliotrope, or violaceous hue mingled in the varying degrees of redness (pallor with heliotrope hue, redness with heliotrope hue, plethora with heliotrope hue, and all intervening degrees), this peculiar colouration being highly reminiscent of that of acutely gassed cases and an evil sign, for few cases recover when once this characteristic hue has become established.

The physical signs in the lungs.—Certain of the main symptoms will be discussed presently, but first we would refer to the physical signs in the lungs. These are extremely variable, and when a large number of cases have been seen one realises that neither the diagnosis nor the prognosis can be gauged by physical examination. Even at the risk of becoming wearisome we wish to emphasise this. A man with only a few rhonchi to be heard in either lung may die as certainly as another who has dullness, bronchial breathing,

bronchophony, pectoriloquy, and crackling râles over the whole of both lower lobes. The extent of consolidation is no measure of the severity of the infection; and a man may die of this disease with practically no lung symptoms during life and no evidence of consolidation post mortem.

In a considerable number of cases the clinical condition may be illustrated by saying that the patient when first seen looks so exactly like an example of lobar pneumonia that when one examines the chest and finds absolutely no abnormal signs at all one is inclined to say, "I am sure he is pneumonia all the same and I expect we shall find the signs of consolidation and probably rusty sputum by to-morrow." One examines the next day, and may again find no abnormal signs, or perhaps only a few scattered rhonchi in front, with subcrepitant râles at the bases behind without dullness or bronchial breathing. One may still expect consolidation signs the next day, and so on; and the case may run its entire course—to recovery after a week, ten days or a fortnight, or to death in one, two, three, four, five, six, seven, or even more days—without any further signs than the rhonchi in front and the non-consolidating râles posteriorly.

On the other hand, the case may start as above, and in a day or two one may find markedly impaired percussion note at one or both bases, with bronchial breathing and sharp crackling râles, bronchophony and pectoriloquy, either of patchy distribution, or frankly all over a whole lower lobe or over a whole lung, or over both lower lobes. In such cases the unwary diagnose croupous lobar pneumonia simply because they are familiar with these signs in lobar pneumonia and forget that they may be also due to any other cause of extensive consolidation, or even to congestion only. In these cases the autopsy findings show this consolidation in the present cases to be due not to croupous pneumonia but to confluent broncho-pneumonia with varying admixtures of hæmorrhage, peribronchial infiltration even to the extent of abscess formation, œdema, turgid congestion, infarction, and pleurisy.

In other cases, again, the physical signs of some kind of consolidation may be pronounced almost from the start; and although these are to be found a hundred times in the lower lobes, especially behind, or in the middle lobe, for once they are found first in the upper lobes in front, there are occasional cases in which the dullness, bronchial breathing, and crepitant râles develop in one or other upper lobes and not in the lower lobes at all.

In another type of case there is no bronchial breathing anywhere, but both lungs—front and back alike—are full of crepitant or subcrepitant râles from apex to base, recalling the signs met with in some cases of generalised pulmonary tuberculosis.

In yet another type, whatever signs there may be elsewhere in the chest, one base becomes completely dull with silence as to breath and voice sounds; the dullness being of variable extent but generally extending a hand's breadth or more upwards from the base. Needling generally discovers turbid fluid in the chest in such cases, and small amounts of pleuritic effusion are common if the patient does not succumb too soon, although large pleural effusions are relatively rare.

Another phenomenon adds complexity to the picture.

This is the disappearance of bronchial breathing, which may have been pronounced and unmistakable a few hours previously, ordinary vesicular murmur now being heard instead. The bronchial breathing may re-develop perhaps a few hours later, or next day, either where it had been heard before, or in another lobe, and again it may disappear and be replaced by harsh vesicular murmur. The explanation of this seems to be the varying degrees of collapse that result from accumulation of thick mucus in the tubes. When a fair area of lung tissue becomes temporarily airless from this cause, bronchial breathing may be heard over it; within an hour the mucus in the tube coming to this part may have been displaced, and the alveoli have re-expanded with air, so that vesicular murmur is heard where a short time previously bronchial breathing was marked.

Apart from consolidation, the formation of fluid in the chest has been infrequent, remarkably so for cases in this Command, in which empyema is so common as to be almost the rule in all pneumococcal and streptococcal infections of the lungs. The coexistence of pleural effusions will be dealt with in the consideration of prognosis, suffice it to say here that its relative infrequency seems to indicate a high degree of virulence of the infecting organism and the incapacity of the tissues to react thereto. Towards the termination of the epidemic effusions became far more frequent in the pneumonic type of case with a high percentage of recoveries.

The sputum.—The cases of fatal "purulent bronchitis" of former years were characterised by the expectoration of immense amounts of sputum—often from 10 to 15 ounces in the 24 hours, this sputum being in the main pure pus, with little froth, with some blood, bright red in some cases, rusty in others, in a minority of the patients. Precisely similar sputum, necessitating the emptying of full sputum pots twice or more in the 24 hours has occurred in one group of cases we have seen in the present epidemic—the earlier and very fatal cases amongst United States troops; but in every other group we have been much struck by the relative paucity and even the entire absence of sputum.

This paucity has not been confined to cases with any particular variety of predominant physical signs. Cases have been encountered with signs mainly of bronchitis with only a little frothy sputum; other cases with only bronchitic signs, and yet an expectoration of 15 ounces of pus a day; other cases in which the signs were those of extensive or confluent broncho-pneumonia with hardly any sputum; others, again, with physical signs of broncho-pneumonia of confluent type and lobar distribution with copious purulent expectoration equal to that which is familiar in "purulent bronchitis" cases.

There is no rule as to the amount of sputum, and those cases that have little sputum are, in other respects, especially as regards prognosis, very similar to those that produce half a pint in 24 hours. What has struck us a good deal in this connexion is that the cases that occur in any particular district tend to conform to one type in regard to the amount

Charts of 5 Cases of Recovery.

Charts of 5 Fatal Cases.

The temperature charts in the cases of influenza and influenza "pneumonia" have been so extremely variable in type that a hundred or more would have to be reproduced if every species were to be depicted. The above serve to represent certain of the commoner types, however. The five on the left-hand side are from cases that recovered; the five on the right-hand side from cases that died. The authors think that the charts and their variability speak for themselves, so they have not commented on them in detail.

of sputum. Probably this is not a universal rule, but it has been a striking phenomenon in the present epidemic in which we have seen large collections of cases in widely-separated districts.

The sputum, when it is abundant, has generally consisted mainly of pus with or without blood; it is then not strikingly frothy. When it is not abundant it still contains pus, but it is often frothy and mucoid in addition. In neither case has it any strikingly offensive smell.

It is often free from blood, but occasionally it has a definitely rusty colour, simulating that of croupous pneumonia to some extent; though even when it is definitely rusty it is seldom of the glairy tenacious consistence that is so characteristic of true pneumonic sputum.

Hæmoptysis.—Apart from more or less altered blood in the sputum itself, actual hæmoptysis has been a very common phenomenon.

In the slighter cases with this condition the sputum pot exhibits frothy mucopurulent material in which occur streaks and splashes of bright red blood in varying quantity. This blood is spat up as a rule independently of the actual sputum, even if synchronously with it. In quite a considerable number of cases this hæmoptysis has attained a degree comparable to that of phthisis. The bed-clothes, wall, and floor have become blood-spattered during a coughing paroxysm, and as much as 10 ounces of bright red blood may be coughed up in a few minutes.

The conclusion has sometimes arisen that an old phthisical cavity must have become lit into activity by the new acute pulmonary infection, but post-mortem examination in such cases has not confirmed this suspicion, and there is little doubt that the hæmoptysis is due in many cases to the opening of small pulmonary arterioles by the acute infective process, in others it may be due to the infarcts in the lungs which are seen frequently at autopsy.

In cases of only slight hæmoptysis streaks and wisps of blood may come from the intensely engorged mucosa of the lower trachea and main bronchi, and in these the prognosis is not absolutely bad; when considerable hæmoptysis occurs it seems probable that it is due to localised lung destruction, with the opening of arterioles before they have time to thrombose, and the prognosis is grave.

We have only once seen a hæmoptysis so abundant immediately before death that the hæmorrhage itself could be regarded as actually the cause of death. On the other hand, we have seen cases with acute and considerable hæmoptysis recover, so that though a very grave sign it is not a hopeless one; when the hæmoptysis has been only in the form of wisps and streaks we do not think the prognosis any worse than it is in the cases generally.

A final reference as to hæmoptysis must be made to a few cases in which, after recovery has occurred and the patient has been apyrexial for several days, he has begun to expectorate quantities of comparatively fresh blood although no alteration in the symptoms occurs. In all these cases—we have seen perhaps eight in all—nothing untoward has developed.

Hæmorrhages.—Hæmoptysis has been common, as just described, but *epistaxis* has been far commoner.

This symptom is not confined to the "pneumonic" cases, but has been met with in a high percentage of the uncomplicated cases. We do not think that the occurrence of epistaxis indicates any special liability of the influenza to develop into the dreaded "pneumonic" or virulent type. In quite a number of cases the epistaxis has been really severe and difficult to control; more often, however, it has been merely a temporary nuisance liable to recur several times but invariably ceasing without treatment.

The blood from the nose has generally been bright red, such as would come from a small arteriole if it were ulcerated; and the prevalence of this epistaxis acquires additional significance when one realises how often the sphenoidal and ethmoidal sinuses contain pus at autopsy (see *Morbid Anatomy*, below), this pus being found to be teeming with pneumococci, sometimes associated with Pfeiffer's bacillus. The epistaxis occurs early; its character suggests erosion by an inflammatory process and encourages the suspicion that the pneumococci gain access not primarily from the lungs, but from the nose, naso-pharynx, and accessory nasal sinuses, and we would consequently advocate the wisdom of using simple antiseptic gargling and nasal douching as a therapeutic measure in all influenza cases in the first stages, and also emphatically as a prophylactic precaution in healthy individuals exposed to the infection.

Hæmatemesis has not been common, but we have met with it in approximately a dozen cases.

In some of these there has been the possibility of epistaxis occurring during sleep, the blood from the nose having passed down into the stomach until enough has accumulated there to make the patient vomit and bring up an alarming amount of blood not really derived from the stomach at all. In a few cases, on the other hand, the vomiting of swallowed blood could be excluded, and true hæmatemesis must have occurred.

In one such case, for instance, the patient was awake all the time; he vomited at 2 P.M., bringing up only mucus and partly digested milk; at 4 P.M., without any nose bleed or hæmoptysis in the interval or afterwards, he vomited again and brought up over a pint of pure blood, darker than fresh arterial. He had no particular abdominal pain, but in this case, and in several others, we felt sure that there was some bleeding breach of surface in the gastric mucosa, possibly of hæmorrhagic erosion type. Such hæmatemesis is not confined to the fatal cases.

Melæna has also been observed: but whether this has resulted from swallowed blood in every case we cannot say. We have, however, met with many cases in which a quantity of bright blood has been passed per rectum; this has particularly occurred shortly before death.

Hæmaturia has attracted notice very seldom. In a small number of cases the urine has been blood tinged or even red or blackish; but in all of these that we have seen the hæmaturia has been part of a definite acute nephritis; the latter has been very common, and blood cells may be found in the urine microscopically in a high percentage of the "pneumonic" cases. Hæmaturia apart from nephritis we have not met with.

Purpura or other form of hæmorrhage into the skin has been very uncommon indeed. In a malady associated with such severe toxæmia

we should have expected purpura to be common. We have met with no case of generalised purpura. One case had extensive purpura of the extremities; another exhibited severe purpura of the legs between knee and ankle, associated with a hæmorrhagic bullous eruption of the same parts. Both recovered.

Several cases have occurred of acute sudden painful oedema of one or both feet associated with diffuse dull red deep seated purpuric tender spots beneath the skin of the dorsum of the swollen foot, similar to those described by Osler in cases of infective endocarditis; possibly both the swelling, the pain, and the tender purpuric spots on the feet in such patients are the result of local changes in the smaller vessels of the parts—thrombotic or embolic.

Hæmorrhage from the ears has been seen by us in one case only; the blood-staining of the pillow that resulted was extensive, but the total blood lost was not great. It was the result, we think, not of any special hæmorrhagic tendency, but of blood-discharge from very acute bilateral otitis media.

Other forms of hæmorrhage have not attracted notice; we have seen approximately 50 of the "pneumonic" cases in the female sex (mainly in the Nursing Staff), but in none has there been any special tendency to undue uterine bleeding.

A further indication of the hæmorrhagic tendency is afforded by those cases which have developed a pleural effusion. In the majority of these cases the prognosis is relatively good, the fluid has been sterile and the preponderating cell has been the lymphocyte. In a few cases the fluid, which has still been markedly hæmorrhagic, has contained pneumococci. In three cases a sterile hæmorrhagic fluid in considerable amount was obtained from one side of the chest and thick streptococcal pus from the other.

The colour of the patient: heliotrope cyanosis.—Of all the features of the "pneumonic" cases we would lay most stress on the colour of the patient. He may not have much colour at all, he may be flushed, he may be sunburnt, or he may be plethoric; but whatever the degree of his facial colour we have always been thankful when this colour has remained red. It may be a sallow face with redness of the lips and ears only, or the patient may be of a rubicund type with general redness of his whole face, or he may be flushed with the unnatural redness of fever; but so long as his lip and ear colour, whatever its degree, is red there is ample room for hope of recovery, no matter what the lung signs, the temperature, the pulse rate, or the respiration rate.

When, on the other hand, to reproduce the colour of the patient's facies, especially the lips and ears, one would need to mix some heliotrope, or lavender, or mauve-blue with red paint to produce the right tint, the prospect is grave indeed, even if at the moment the patient seems comfortable, has no signs of consolidation in either lung, is sleeping fairly well and taking nourishment, has no more than an ordinary degree of pyrexia, a good pulse rate, not unduly fast, and a respiration rate that may not strike one as being unusual in the circumstances.

This colour may be confined to the lips and ears, or it may affect the rest of the face as well; in either case it is the surest basis on which to pick out those cases in a ward that are likely to be dead in a day or two from those who, unless they themselves develop the same hue later on, will most probably recover. It is not impossible for a "heliotrope cyanosis" patient to recover, but that he should do so has been the rare exception in this epidemic. The tint is precisely the same as that which struck us so much in the cases of fatal "purulent bronchitis" in 1916 and 1917; and it has been commented on by many other observers.

The actual colour of the patients differ greatly, because some have much, other little, blood in their superficial capillaries, and there is every intermediate degree; but common to them all is the mauve or heliotrope element that would have to be mixed with the red to reproduce the hue in a painting. We do not pretend that all the serious types are like the second of the coloured illustrations which we reproduce, but many of them are exactly like it, and we have taken an unmistakable case to illustrate with emphasis what we mean. We would also lay much stress upon the fact that the dreaded tint generally develops before the patient himself seems otherwise any more ill than those around him who are going to recover. Once the hue is there, however, treatment, as we have elaborated below, seems totally unavailing.

The change of colour may come on in a few hours. In the morning the man may be simply flushed but of good red colour, as in Plate I. By the evening or the next morning, not necessarily feeling much worse in himself and still quite cheerful and clear-headed though ill, he may have developed some degree of the colour of Plate II.; and then it is generally a matter only of hours, or at most a day or two before he becomes of ghastly appearance like Plate III.

At one time we thought the colour might be due to methæmoglobinæmia, but the spectroscopic shows no abnormal pigment in the blood in these cases, nor is there any defect in the oxygen-carrying capacity of the blood (see below); the condition is one apparently of what Professor Haldane terms "anoxæmia," precisely similar to what is seen in gassed cases at the Front and possibly due to analogous causes, to judge from the histological changes seen in the lungs.

The breathing.—One of the most striking features about the breathing in the "pneumonic" cases is the absence of orthopnea even in patients who are breathing very rapidly.

Amongst female cases the desire to be propped up by pillows is not so uncommon, but in regard to men one can go round a hospital and see upwards of 500 cases in all stages of the disease, and it will be exceptional to find even one who is desirous of being so supported. The great majority lie at full length, and although it is probably good

practice to vary the patient's position, so that he is not too long continuously on his back, the patient himself prefers to lie flat.

This absence of orthopnea applies as much to those with confluent consolidation as to those who have signs of bronchitis only. It is not due to the patients being too ill to care, for the mild, the medium, and the severe are alike in this respect. The probable explanation is that the pulse remains good until quite at the very end, and there is little dilatation or failure of the right ventricle. Failure of the right heart is the commonest cause of orthopnea in cases of dyspnea without obstruction to the bigger air-passages, and it is a striking feature of the hearts of these cases at autopsy that its dimensions, right and left sides alike, remain practically normal. In a word, the cyanosis is not cardiac.

The patients breathe with greater rapidity than normally, silently as a rule, except in the terminal phase, and each respiration is short and shallow. When left to themselves the patients may be breathing only 28 or 30 times a minute, but the slightest exertion, such as that entailed by rolling to one side or trying to undo the buttons of the shirt, increases this rapidly to 40, 50, or 60 per minute for the time being, any liability to cyanosis being markedly increased at the same time. There is clearly very little reserve power in the respiratory system, but very few patients complain of difficulty in breathing unless the respiratory movements are interfered with by the pain of acute pleurisy. It is not a *dys-pnea*, but rather a *tachy-pnea* or *poly-pnea*.

Cough is troublesome in some cases, almost absent in others.

It is apt to recur in paroxysms, and these may be very exhausting in the cases in which there is little sputum. When the latter is abundant it comes up fairly easily so long as the patient has a reserve of strength; in bad cases a time comes when the effort of coughing is too much, and the patient, whose lungs are full of what would be better expelled, neither coughs nor expectorates at all.

We have found that a persistent cough is an indication for the examination of the chest (undue examination is, of course, to be deprecated in these "pneumonic" cases) for evidence of fluid.

The pulse.—The heart does not fail as a rule, unless quite as a terminal event.

It is remarkable how often, when the general appearance of a patient shows he has only minutes to live, the pulse may still be quite regular, of good volume, and not much faster, perhaps, than 120 per minute. Earlier, the pulse-rate is generally not faster than corresponds to the degree of pyrexia; and often it is less rapid than the ordinary temperature-pulse ratio would lead one to expect. There are, of course, cases in which irregularity develops, or the pulse races towards the end; but, broadly speaking, the condition of the heart remains satisfactory throughout and the patients do not die from cardiac failure.

It is noteworthy that in no single case did we meet with pericarditis either clinically or post mortem. This, we think, will not prove the case in records from other districts, and we are surprised at not having seen one case.

In one single case typical auricular flutter developed; this appeared to be a direct result of the influenza itself and not of the pneumonic complications, for it was already present when the latter supervened during convalescence from an ordinary influenzal attack. The man made no complaint about his heart though it was beating over 250 times a minute and the pulse waves were too small to feel, and he was doing well until he contracted pneumonic complications a few days after he had seemed to have recovered. He had in fact been apyrexial for two days and had got up in the ward. Digitalis in large doses had an excellent effect upon the pulse rate, which in just 96 hours from the institution of treatment fell to 90 beats to the minute.

Herpes facialis.—Herpes of the lips or chin or *alæ nasi* has occurred in a small number of cases, roughly speaking 5 per cent.

The eruption has seldom been extensive, though sometimes the vesicles themselves and the inflamed area on which they stood have become a hæmorrhagic scab. In one case only has this hæmorrhagic tendency been extreme. In this patient the wide area of the eruption, affecting both nostrils, the upper lip, the lower lip, both cheeks near the mouth-margin, the chin and the neck for some distance below the jaw, with the accompanying hæmorrhage into the area of the eruption, was like that of severe *syprochatois* *ictero-hæmorrhagica*. But it was not followed by a fatal result.

Herpes of the ears.—Sometimes with, but as often without, herpes of the lips and face, herpes of both pinnae has occurred.

The vesicles were generally disseminated over the outer aspects of the pinna either singly or in groups of two or three, and not as coalescing patches. The eruption here was not associated with any other special feature in the cases, but the soreness of the ears was a trouble to the patient.

The eyes and eyelids.—Quite early in the disease the upper eyelid tends to droop, as though the patient were half asleep. This is illustrated typically in Plate I.

In the purely influenzal cases, or in the "pneumonic" cases that are not severely affected, this drooping of the upper eyelids is inconstant, and the patient opens his eyes fully when his interest is aroused; but in the severer cases the droop persists even when the man is spoken to; it is more than a mere state of being "heavy-eyed" then, and it is an unfavourable sign. The eyelids are those of a man who is very toxic or half doped, and at the same time, in bad cases, the conjunctiva is dull and the eye looks dazed. The condition supports the view that the symptoms are due less to the condition of the lungs themselves than to the extremely toxic state of the blood and tissues generally.

Delirium.—Mild degrees of delirium, especially in the early hours of the morning, have occurred even in the purely influenzal cases. In those with "pneumonic" complications there have been remarkable variations in the

degree of delirium presented by patients at different periods of the epidemic and in different areas of the Aldershot Command.

At one time hardly a single "pneumonic" patient out of hundreds presented any delirium at all worth mentioning; then we meet with a series of cases in which delirium lasting day and night, with hallucinations and a tendency to be physically and vocally violent, was pronounced. This delirium seemed unrelated to previous alcoholism, and the cases in which it was most marked were not necessarily fatal. More common than violent delirium with hallucinations was the low muttering type, with the tendency to get shakily out of bed until nurse came and put the patient quietly back again.

Upon the whole, however, delirium of either mild or violent degree was less marked a feature even of the severe and fatal cases than one would have expected. On the contrary, it has been heart-rending to see heliotrope-cyanosed lusty great men breathing 50 to the minute, and obviously bound to die within a brief hour or two, still clear-headed, able to talk connectedly, not complaining and not obviously in physical distress, yet fully conscious of what is about to happen to them by reason of what they know has happened to their fellows from the same regiment a day or two before.

On the other hand, there is a type of termination in which a restless coma precedes death by many hours or even by a day or two. The patient lies low in bed with his head thrown back, moving his limbs or his whole trunk restlessly from time to time, with partly opened mouth, a ghastly yellow pallor of the hollow sunken cheeks, pallid lavender hue of lips and ears, rapid sighing respiration, incontinence of urine and of faeces, a heavy closed-up cellular sort of smell about the bed, but complete oblivion and total absence of any suffering.

Subsultus tendinum.—Apart from delirium, a high percentage of the more serious cases, whether fatal or not, has exhibited the following condition.

This is not so much the "picking at the bedclothes" tendency as marked involuntary jerkings and twitchings, now of one leg, now of the head and neck, now of a wrist or fingers, now of a whole arm, now of one side of the abdomen or of the back—an extreme degree of *subsultus tendinum*. So very twitchy and jerky have some cases been that an overdose of strychnine has been the first suspicion, but the condition has been common without strychnine or any other drug having been used at all. The symptom is further evidence that the patients suffer from generalised toxæmia of severe degree, the badly oxygenated state of the blood being perhaps an added factor in the *subsultus*, the nervous system being starved of oxygen by reason of the anoxæmia.

Otitis media.—Deafness of some degree has been a fairly common symptom, both in the purely influenzal cases and in those with "pneumonic" complications.

Here and there a patient has become stone-deaf for the time being, even when no quinine, aspirin, or salicylate has been administered. It seems likely that the chief factor in the production of this deafness is microbe infection, perhaps pneumococcal, spreading from the nasal mucous membrane to the Eustachian tube. In further confirmation of this view is the fact that, though many of the cases have lost their deafness spontaneously after a few days or a week, some have had severe earache followed by otorrhœa. The radical mastoid operation has been required in two such cases already, and there may be others still to be similarly dealt with. In one case the bilateral ear discharge was so acute that it consisted of almost pure blood. Unfortunately we have not ourselves been able to investigate any such ear case bacteriologically.

Parotitis.—In about a dozen cases—one of the severe "pneumonic" type which ended fatally, the others of simple influenzal type—unilateral or bilateral swelling of the parotid glands has developed when the patient was already in hospital for his influenzal attack.

The chief difficulty in these cases has been to decide whether they were examples of mumps developing during influenza or whether they were infective parotitis other than mumps arising as a complication of influenza, and this difficulty has been increased by the knowledge that an epidemic of mumps has been simultaneously present in the command. Orchitis did not occur, but even if it had done so the further difficulty of possible gonococcal orchitis would have presented itself—such orchitis is met with so often in men who fall ill with something else. None of the parotid glands involved in our cases ended in suppuration. On the whole the swelling, whatever the degree, was relatively painless, and ability to open the mouth fully was comparatively unimpaired.

Jaundice.—Jaundice has been quite uncommon in the cases in the Aldershot Command.

No case has presented more than a slightly icteric tinge of the conjunctiva. Through the courtesy of Captain Means, United States Medical Service, however, we have seen 15 cases of definite jaundice in "pneumonic" influenzal cases in United States troops; the condition of all these men was grave at the time. Full details of these and others will, we hope, be published by the United States authorities.

The smell of the patients.—Just as many typhoid fever patients have a peculiar smell which is difficult to describe, but which is none the less almost characteristic, so do many of the influenza-"pneumonic" cases exhibit a peculiar faint indefinite smell, best noticed, perhaps, when the bedclothes are first turned back for purposes of chest examination.

It is not the sour smell of perspiration, nor is it merely fetor from the coated tongue or theordes that are apt to collect in lips and gums in spite of the most careful nursing. It could not be called pathognomonic, but it has seemed to us worth while to call attention to it. More than once it has been so pronounced that we have asked whether

the patient has had a small dose of paraldehyde or any such drug some time previously; but the smell seems to have no relation to any drug that has been given.

Ⓒ In several cases there has been quite a different smell—a real stench, not of the mouth or of the sputum, nor the result of incontinence, but of the patient's living body generally. It has no particular application to those who have died of the disease, for in no case at autopsy has the body presented any unusual odour, nor do the tissues decompose or become evil-smelling with any undue rapidity, at any rate at the temperature of the month of October.

Nephritis.—A high percentage of the "pneumonia" cases suffer from acute nephritis, but this fact would be missed if reliance were placed upon clinical evidence alone.

There is no œdema of the legs, back, or eyelids. The amount of urine passed daily is not lessened beyond what one would expect from the pyrexia. In a series of cases daily measurements of the urine passed varied between 45 and 70 ounces, with an average of 54 ounces.

It is very exceptional to find enough hæmaturia for it to be recognised by the naked eye. In the course of routine urine examination, however, albuminuria is found in some degree in nearly all the severer cases; and in quite a large number the amount of albumin present is from 1 to 5 parts per 1000. In association with renal epithelial cells, and fragmentary tube casts, generally epithelial and often ill-formed owing to the acuteness of the condition. Red blood corpuscles are seldom seen.

It is most important that absence of all œdema in this type of very acute nephritis should be realised to be the rule and not the exception, and we would urge that the routine examination of urines should be carried out with even greater zeal than usual during an epidemic of this sort lest patients should be discharged as cured when really they are still nephritic. It is from cases such as these that "Rose Bradford kidneys" arise later on—the small, white, granular kidney of "unknown" origin.

Large, red, blood-oozing kidneys of the type seen in acute scarlatinal uræmia have been almost constant at the autopsies of the fatal cases, and the occurrence of this acute nephritis is further evidence of the infecting agent, or at any rate its toxins, being widespread throughout the body, the "pneumonic" part of the disease being but a portion of the whole.

Localised abscesses.—The commonest form of localised abscess in these cases is empyema.

Acute pleurisy is the rule rather than the exception. In many cases this remains dry, but in many others it leads to the exudation of a small amount of fluid, thin but turbid, often blood-stained, not actual pus, though it contains numbers of polymorphonuclear leucocytes and organisms such as pneumococci. In fatal cases death generally occurs before there is time for this to change to true pus, and in cases that recover the fluid most often re-absorbs spontaneously, notwithstanding the presence of micro-organisms and pus cells in it. Here and there, however, we have found cases in which the fluid has gone on accumulating, and far from this proving a bad omen, the majority of such cases have ultimately done well.

We do not think it wise to resort to surgical treatment of the empyema with the same rapidity that one would adopt were the infection in the abdomen. It has seemed to us that when the infection thus shows a strong attempt at localising itself to a definite pus-focus the virulence of the general toxæmia or septicæmia has lessened, as though from the formation of a "fixation-abscess" (*vide infra*). We have come to regard it as a source for congratulation when one of these patients, very gravely ill, develops a definite empyema; our view upon the prognosis improves at once, and we have formed the impression that, unless there are strong individual reasons to the contrary, it is wiser to wait a whole day, or even longer, before resecting a rib.

Another point that has impressed us in this connexion is that simple needling of the chest has been so often followed by improvement in the patient's general condition that we would advocate such needling being done with less hesitation than is generally the case.

Subcutaneous abscesses of pyæmic nature have been seen by us in two cases only.

Although recovery was slow both these cases, very gravely ill for a long time, ultimately recovered. Painful, slightly swollen red areas, generally of small size, developed now in one part, now in another, perhaps a dozen altogether in the course of four or five days. One or two of these broke down into pus, softened, and incision was necessary, the rest resolved by themselves without forming abscesses. Very grave though the outlook had appeared at one time in both these cases, we are inclined to think the subcutaneous formation of abscesses helped these patients to recover in some obscure way. These cases may be analogous to that of the "fixation abscess" produced in the manner described below, and suggest a deflection of the toxins to one focus, converting a septicæmia into a comparatively benign focus of infection.

Hemiplegia.—This occurred in one case only, and it was preceded by auricular flutter for some days. We thought the hemiplegia most likely due to a cerebral embolus from an intra-auricular clot rather than to a cerebral hæmorrhage or to local thrombosis.

Phlebitis of one or other leg, with typical painful swelling of the whole limb, was met with in half a dozen cases.

In one or two the leg condition developed whilst the general disease was at its height; in the others it was a phenomenon of early convalescence. In none of the cases did the vein-clotting lead to any suppurative locally, and the patients recovered gradually without further complications.

Skin rashes.—We have referred above to one case of purpura of the legs associated with hæmorrhagic bullæ between knees and ankles, and to a number of cases exhibiting curious painful purple spots over the dorsum of the foot

accompanied by general œdema of one or both feet. We have also referred to the absence of any generalised purpura in our series of cases, though so many of them were so extremely toxic or septic, and we have discussed herpes of the lips and ears.

Other skin eruptions were infrequent.

In a small number there has been acute inflammatory reddening of the skin around the nose and nostrils, spreading for a variable distance over the face, and presenting the characters of facial erysipelas; these cases did not do badly.

In several there has been a widespread erythema of limbs, trunk, neck and face, resembling the rash of scarlatina at first sight, but exhibiting no characteristic puncta and differing from scarlatina in that neck and face, as well as the trunk and limbs, might be involved by the rash. This erythema could not be attributed to any drug, such as aspirin, belladonna, or salicylate in some of the cases at any rate, and it was not the result of serum injections, though serum rashes did occur in some of the cases treated with antitoxic serum.

In one case there was a generalised morbilliform rash without the coryza or other phenomena of measles.

Meningitis.—Notwithstanding the extreme severity of the general infection and the recovery of pneumococci or streptococci from the blood and viscera post mortem and even during life, meningitis has not been met with as a phenomenon of influenza-pneumonic cases.

Several patients suffering from acute meningitis have been admitted as cases of influenza, but these have all been found to be meningococcal. A certain number of cerebro-spinal fever patients come in all the year round, but the number has, on the whole, been appreciably smaller during this influenza epidemic than it has been in general. It would not be surprising if here and there amongst the thousands an instance of simultaneous influenza and cerebro-spinal fever should occur, and we believe that this has happened, but we do not regard the meningococcal meningitis we have thus seen as essentially related to the influenza. The existence of a widespread epidemic of severe influenza, however, does make the early recognition of cerebro-spinal fever more difficult than ever.

In no case of "pneumonic" influenza seen by us post mortem has there been any obvious meningitis.

Finally, a fairly extensive investigation of severe cases of influenza with special reference to the cerebro-spinal fluid, yielded in all cases an absence of any evidence of increasing intracranial pressure; the fluid was always clear and contained no excess of albumin, very few cells, and was always sterile.

Ruptured rectus abdominis muscles.—In upwards of 20 cases we have seen spontaneous rupture of one or both rectus abdominis muscles, generally in that portion of the muscle which lies below the level of the umbilicus.

The effort of coughing is apparently the immediate cause of this rupture, but the muscle has become diseased before it breaks. Sometimes one finds the rectus extensively affected post mortem without actual rupture having occurred. In most instances, even when there has been no rupture, the affected portion of the muscle presents the same sort of appearance as does the breast of a pheasant when one skins the bird after it has been badly shot at close quarters; the muscle is dark crimson, of bruised appearance, full of diffusely extravasated dark blood, friable, readily torn by the fingers, and it may be squeezed into a pulpy mass without much force.

Why this muscle in particular should be affected in this way we do not know, unless it is the result of vessels in it giving way in consequence of violent coughing efforts. Doubtless the lesion is related to Zenker's degeneration of the muscle such as occurs in other infective maladies, enterica for example; but in ordinary Zenker's degeneration the muscle is pallid and not hæmorrhagic, whereas in the present cases the lesion has gone on to a local hæmorrhagic pulpy state even if the muscle has not been actually ruptured during life. Both rectus abdominis muscles are apt to be affected at the same time in cases in which either is affected at all; that is to say, bilateral rupture has been as common as unilateral.

Subcutaneous emphysema of the chest wall.—In about 15 cases altogether palpation has elicited the striking phenomenon of widespread subcutaneous crackling of the deep tissues of the chest and neck and back, the result of subcutaneous emphysema.

This has always started on one or other side of the thorax itself, generally in front or towards the axilla rather than behind, spreading rapidly over a variable extent of the whole thorax and even to the neck, where it may form a complete collar of crackling swelling. It is an event of very grave import, though one case at least recovered after its development.

It is generally difficult to demonstrate post mortem how the air reaches the subcutaneous tissues. One explanation is to assume its origin from the lung root via the mediastinum; but in some cases at least it results from a small acutely necrotic focus in one lung ulcerating directly through both layers of pleura into the extra-pleural tissues. Minute or small superficial abscesses in the lungs are met with in quite a number of cases; these are surrounded by sticky pleuritic exudate sufficient to prevent the development of pneumothorax when the visceral pleura is ulcerated through at a pin-hole point. The parietal pleura becomes infected by direct extension, and it only needs a pin-hole perforation in it, too, to cause the subcutaneous emphysema of the chest wall which has been so striking in certain cases in this epidemic.

That acute ulcerative or focal necrotic changes in the lung tissue are in this way the cause of the emphysema is further suggested by the way the onset of the subcutaneous crackling has not infrequently been simultaneous with acute hæmoptysis, as though the focal lung necrosis opened up an arteriole at the same time. Nearly all these patients die.

MORBID ANATOMY.

The Lungs.

Although we believe that the infection is widespread and not confined to the lungs, the patients exhibit a preponderance of chest phenomena, so that naturally the lungs attract first attention at autopsy. We would emphasise, however, the bacteriological findings in the heart blood and spleen, and the prevalence of acute nephritis, as indicating that the lung lesions are very far from being the whole basis of the so-called "pneumonic" cases. We think that the fatal disease is an influenza-pneumococcal or influenza-streptococcal septicæmia with more or less marked local lesions in the lungs, but we do not think it is in the main a lung disease any more than we would regard enterica as essentially a bowel malady, notwithstanding the ulcers in the ileum being the chief lesions found post mortem in typhoid fever cases.

In the next place, although the physical signs during life may often be precisely those with which one is familiar in lobar pneumonia, it is absolutely exceptional to find the straightforward typical hepatisation—red or grey—of true croupous pneumonia.

Only in one single case have we found what appeared to be true red hepatisation—and this was in two-thirds of one lobe only, the rest of the lungs presenting broncho-pneumonia, hæmorrhage, and bronchiolitis of the type described below. In one other case a small portion of one lobe looked like grey hepatisation in contrast to the multiple and diverse lesions elsewhere in the same lung.

True lobar pneumonia is not what is found post mortem in the vast majority of the cases. Whole lobes may be consolidated and in an anatomical sense the lesion is "lobar"; but the term "lobar pneumonia" has come by common consent to be a particular and well-defined variety of lobar consolidation, and one does not use the term "lobar pneumonia" of every form of lung consolidation that happens to have a lobar distribution.

In the next place, though some variety or degree of consolidation has been the rule throughout the serious cases in the present epidemic, we would lay much stress upon the fact that here and there an autopsy reveals practically no lung consolidation at all.

The lower lobes may be dark-red, almost black-red, heavy, oedematous, congested, the upper lobes pale and distended; but no part of any lobe actually sinks in water, or, at any rate, only tiny portions, carefully searched for, found with difficulty, and cut out with fine scissors. These cases without consolidation have run almost identically the same clinical course as those with much, and it is one of the striking features of the disease that the extent of the lung consolidation is no measure whatever of the severity of the infection.

This is precisely what struck us when we wrote in 1917 about "purulent bronchitis." Fatal cases of the latter exhibited varying degrees of broncho-pneumonia associated with bronchitis or bronchiolitis or without any broncho-pneumonia at all. And we believe that the "purulent bronchitis" then described was only one type of a condition which has recently shown itself to be remarkably protean.

The next point to emphasise is the absence of thick abundant bronchiolar pus in our own cases at the present time.

In the "purulent bronchitis" cases one of the most marked phenomena post mortem was the way in which thick yellow pus welled in smaller or larger spots and dots from all the bronchioles when the lung was cut. This peculiarity has been strikingly absent in the great majority of the recent Aldershot influenza cases, only small quantities of pus being expressible from the tubes, as a rule. And yet in precisely similar "influenza-pneumonia" cases seen in another command during the same epidemic the amount of pus expressed from the bronchioles was similar in amount to that of the "purulent bronchitis" cases. There is nothing constant about the lung lesions, and what may be true of a group of cases in one place may not hold good for another group of cases elsewhere, although the disease in general is clearly the same in both.

We will now try to indicate the kind of lesions met with, as a rule. It is not easy to depict these because they are so variable in the degrees and extent to which the following various conditions may be mingled together, namely:—

| | | |
|--------------------------------|---|---------------------------------|
| Broncho-pneumonia. | Multiple small areas of collapse. | Pleurisy. |
| Oedema. | Massive collapse. | Compression (by fluid). |
| Extreme congestion. | Formation of abscesses, generally small, but often multiple and aggregated. | Interstitial emphysema. |
| Diffuse hæmorrhage, not solid. | | Bronchitis and peribronchitis.* |
| Solid hæmorrhage. | | Gangrene. |
| Infarction. | | |

* Difficult to demonstrate macroscopically, but shown to be extensive microscopically.

One case may exhibit extreme congestion and oedema, with disseminated non-confluent broncho-pneumonia, subpleural hæmorrhages, and angry-looking purulent pleuritic lymph.

The next may have complete consolidation of both lower lobes by confluent broncho-pneumonia without any pleurisy at all.

The next may have not lobar consolidation but irregular masses which are more easily felt than seen, of deep crimson consolidation due to combined broncho-pneumonia, collapse, and hæmorrhage, scattered widely through all the lobes of both lungs, with or without acute pleurisy.

The next may have one entire lung apparently healthy, the upper lobe of the other pale and over-distended, and the remaining lower lobe

heavy, nearly but often not totally airless, of a consistence to suggest spleen rather than liver, and of a dull, deep-slate colour externally, still further suggesting a post-mortem spleen.

The next may have broncho-pneumonia, more or less extensive in the lower lobes with firmer wedge-shaped areas amongst the latter strongly suggestive of infarcts; whilst the upper lobes, free from broncho-pneumonia, may present from one to half-a-dozen or more typical infarcts, generally not large, of deep red colour, contrasting with the paler hue of the rest of the upper lobes.

In another case these infarcts may not be uniformly deep red, but pale, with crimson margins, due to the breaking down of the central parts into one or more incipient small abscesses.

Again, there may be no definite infarct, and yet over a more or less circumscribed region of one lobe, and often just below the pleura, as if they were originally in an infarct, one may see 20 or 30 pale yellow, slightly prominent areas, each of which turns out to be an incipient abscess or even a definite necrotic focus from which the contents can be washed out with a medium stream of water or readily expressed with the finger. It is from such superficial abscesses as these that perforation of both layers of pleura and consequent subcutaneous emphysema may arise; and if this is the sequence of events it is easy to understand why the development of subcutaneous emphysema generally prognosticates a fatal termination.

What the pathology of the infarcts is we cannot say with certainty.

Very possibly they are thrombotic and not embolic, in which case they point to severe changes in the vessel walls and perhaps in the blood itself. On the other hand, when one considers the frequency of purulent infection of the sphenoidal air cells (see below) one feels that thrombosis of venules in the neighbourhood of the base of the skull, where they are difficult to demonstrate either clinically or post mortem, is not an improbable event, leading perhaps to small but virulent septic emboli of the lungs with infarction and the formation of abscesses in the infarcts.

Perhaps both thrombotic and embolic infarcts occur; in either case their occurrence, not by any means in all cases but none the less in many, is a reminder that the vascular route of lung infection must not be forgotten. It seems highly probable that much of the lung mischief is due to direct invasion through the respiratory passages—from main bronchus to bronchioles and from the latter to the alveoli, bronchitis preceding broncho-pneumonia. But another route may be via the blood stream, thus accounting for the great severity of the infection and its high mortality.

Apart from actual infarcts, hæmorrhage into the deep lung tissue has been very common. Sometimes it is diffuse and difficult to demonstrate, owing to the already very deep crimson colour of the congested lung; but even then one can see it in the form of very dark, almost black, patches or ill-defined diffuse network, or a bigger localised mass which can be felt and which sinks in water.

The lower lobes have been affected very much more than the upper, though apical consolidation with confluent broncho-pneumonia is met with in a few instances.

With few exceptions the colour of the lower lobes has been deep crimson from extreme congestion, and very marked oedema of the lower lobes has been the rule, frothy blood-stained serous fluid pouring from the cut lungs when they are gently squeezed. This oedema is responsible for much of the increased weight of the lower lobes, and it occurs equally whether there is much broncho-pneumonia or little.

Although we have met with many cases with multiple small areas of necrosis or abscess formation, and many in which the lungs were pulped with ease by the hand, much in the same way as a decomposing spleen may be squeezed to pulp, we have met with no case so far of actual gangrene of the lung, and there has been no odour suggesting incipient gangrene. Perhaps this is due to the rapidity with which the disease progresses, so that patients have died before there has been time for true gangrene to develop.

We have met with no case of pneumothorax.

Pleurisy has been very variable in its incidence.

Quite a number of consecutive cases have exhibited acute pleurisy of the "lack-lustre" type with little or no fibrinous exudate and no free fluid, the acute pleurisy affecting one or both lower lobes, and much less often an upper lobe. Another group of cases have demonstrated no naked-eye evidence of pleurisy, although the intra-pulmonary lesions may be various and abundant. It has been exceptional to find much free fluid in the pleural cavity; one or two ounces of turbid blood-tinged fluid are present in a fair number of cases, but a large effusion has been exceptional post mortem. This is partly due to the recognition of fluid in the chest during life and its removal by aspiration, for fairly large pleuritic effusions have not been particularly uncommon in the wards. It is also partly due to the recovery of the whole of those cases in which the focussing effect of a copious effusion has been the patient's salvation.

The thin turbid fluid is clearly of the nature of an empyema, but it is not actual pus; it may become pus and need operation clinically, but we have not seen more than one or two cases of actual empyema in this disease post mortem. We think the empyema cases tend to do well for the reason stated above.

Interstitial emphysema in the form of a fine melon-rind network beneath the pleura has occurred in several cases; the condition is doubtless the result of inflamed alveolar walls giving way under the stress of coughing efforts.

Acute bronchiolitis is nearly always present.

The histological changes in the lung tissues must be postponed for a subsequent communication. We would only say here that in many sections there is an appearance in and around the bronchioles and inside the alveoli which at first makes one think that the paraffin has been imperfectly removed from the tissue. We thought at first that this was actually the cause of the appearance seen, but on further testing it seems that the appearances are due to a homogeneous structureless non-cellular exudate which fills the bronchioles and the peribroncholar tissues and forms as it were a plastering round the inside of the alveoli. It is not fibrinous like the exudate of croupous pneumonia. Presumably it is an albuminous exudate, coagulated in the process of fixation, and it is very similar to that which can be seen in fatal cases of poisoning by chlorine gas.

This albuminous exudate throws much light on the nature of the dreaded cyanosis. If the oxygen in the alveoli has to traverse this albuminous layer in addition to the alveolar wall before it can get to the hæmoglobin of the blood, it is evident why there is such marked anoxæmia.

Other Post-mortem Findings.

The larynx, trachea, and bronchi.—Starting at a variable distance down the trachea, often near the top of it and sometimes in the larynx itself, there is reddening and congestion of the mucosa, the depth of crimson increasing rapidly as one passes down the trachea, until in the main bronchi the dark-red colour is extreme.

That there is tracheitis and bronchitis in addition to whatever changes there may be in the lungs suggests strongly that, even if a blood infection does occur as well in the way we suggest, invasion of the respiratory tissues by extension from above downwards is pretty constant. In addition to deep crimson congestion there is often a granular appearance of the surface of the mucosa of the lower part of the trachea and of the main bronchi, suggestive of a small amount of exudate upon the surface. This may even reach the stage of giving the appearance of a very fixed milky film over a crimson base, but we have not seen the definite membranous exudate described by others.

When viewed in an oblique light the inflamed mucosa often exhibits multiple minute depressions, very shallow but well defined. These look like extremely small surface ulcers not penetrating the whole thickness of the epithelial covering, but they may, on the other hand, be merely normal unevennesses exaggerated by the congested swollen state. As yet we have not settled this point histologically.

The bronchial glands.—The lymphatic glands below the bifurcation of the trachea have been found enlarged and crimson from injection in practically every case, and as a rule they have been not merely large but very large.

In one case only had actual suppuration occurred in a big gland below the right bronchus; in this instance it contained fully 2 drachms of pus. It had not burst to produce mediastinal suppuration, though it seemed clear that this must have been the result if the patient had survived a day or two longer.

The glandular infection is not confined to those about the main bronchi; the glands in the root of each lung, in the superior and posterior mediastina, and the deep glands up the neck even as high as the cricoid cartilage also are often enlarged and deeply crimson from inflammatory congestion. We have not noticed similar involvement of glands elsewhere—for example, in the abdomen.

The thyroid gland.—Considerable enlargement of the thyroid gland has been the rule.

In one or two cases the swelling has not been less than that seen in an average case of Graves's disease, and the isthmus was enlarged in the same proportion as the lateral lobes. Presumably this enlargement of the thyroid is the result of the general toxæmia, corresponding in this respect to its enlargement in some other forms of toxic trouble; at any rate, it has been quite pronounced and almost constant in our cases.

The heart.—The most remarkable feature about the heart is the general absence of dilatation.

In quite a large proportion of cases there has been no trace of dilatation; in a fair number of others there has been some dilatation of the right side, but this has seldom been extreme, perhaps enough to cause the apex of the heart to be formed about equally by right and left ventricles. Most often the heart has appeared of normal dimensions and the apex has been formed entirely by the left ventricle. This absence of dilatation accounts for the clinical absence of orthopnoea.

Whether or no pericarditis ever occurs, we have not met with one case of it yet; and the same applies to endocarditis.

We have also been struck by the absence of subpericardial petechiæ, such as are generally met with in very toxic conditions.

The spleen.—In many cases no enlargement of the spleen has been evident; in many others it has been slightly enlarged—half as big again as normal, or, exceptionally, twice its normal size. It has never been pronouncedly big—never big enough, for example, to have been palpable below the rib margin.

In most cases the splenic substance has looked normal. In a few there have been multiple small areas of increased firmness and darkened colour, due apparently to quite small infarcts. In two cases there have been massive and unmistakable infarcts, one of which was already softening into an abscess. Whether these were embolic or thrombotic it is difficult to say, but in the absence of endocarditis their thrombotic nature seems the more likely.

In one or two cases there have been multiple ill-defined small areas paler than the rest just beneath the capsule, not firm like infarcts, not palpable at all, and yet on close inspection seeming to be very slightly swollen above the general contour of the organ. None of these have shown any tendency to break down, but there have been granules and tags of recent fibrin on their surface, so that they would appear to be foci of localised infection in the spleen with focal acute capsulitis over them.

The liver.—The liver has been in nearly all cases of a paler brownish-red colour than normal and moderately increased in bulk, but otherwise not obviously affected. The naked-eye changes are those common to any acute febrile illness of short duration. There has been no undue congestion, still less any nutmeg change.

The stomach, intestines, and vermiform appendix.—The alimentary canal has not exhibited any particular change.

We have had no case of pneumococcal or streptococcal peritonitis. The stomach and intestines have been relatively empty, for the patients have been too ill to take food. There has been no special tendency to over-distention of either the stomach or the bowels with gas. The vermiform appendix has not shown any notable change. We mention this because there has been a tendency elsewhere, we have been told, for certain of these influenza-pneumonia cases to develop acute appendicitis.

The kidneys.—These, in the fatal cases, have presented uniformly, the same, or approximately the same, appearances.

They are of slightly larger size than normal, the capsules peel readily, the stellate veins upon the surface are not markedly obvious, the colour is dull purplish red but not strikingly abnormal, but on cutting each kidney open in the ordinary way and leaving it to lie for a moment, the cut surface rapidly becomes obscured by dark red blood which wells slowly but steadily from every part of the organ, particularly from the glomerular region. On close inspection one can see the reddened swollen glomeruli fairly easily, and on pressing the organ the blood oozing becomes still more pronounced.

There is no evidence of cardiac passive congestion, the pyramids are not particularly more cyanosed than is the cortex, the whole condition is reminiscent of acute scarlatinal nephritis. After scarlet fever the large red kidneys are described as "blood-dripping"; in the present cases the kidneys are rather "blood-oozing" than "dripping," though if they are held up and gently pressed they drip blood slowly in fair amount.

Histologically there is confirmatory evidence of acute nephritic changes, particularly of the "acute glomerular" type. Details of this, as of other histological appearances in these cases, must be kept for another section; but that so many, if not all, of these fatal influenza-pneumonia cases have acute nephritis even though they have no oedema is, it seems to us, a point of much importance.

The sphenoidal and other accessory nasal sinuses.—We have examined the sphenoidal and ethmoidal air cells in 20 consecutive cases.

In one only was there no naked-eye evidence of disease of one or other or both, particularly of the sphenoidal which lends itself most easily to clear examination. In most of the 19 there was definite pale bright-yellow pus in the sphenoidal air cells: in several this pus squirted out on to the chisel used for opening the bone. When there was not thick yellow pus there was turbid serous fluid with angry red congestion of the lining membrane and adjacent parts. Doubtless this is one factor in the severe headache from which some of the patients complain, when they are not too ill to complain at all.

We did not examine the frontal sinuses or the middle ear as a routine. We are much impressed, however, by the frequency with which the sphenoidal air sinuses are infected or full of pus, and we must add in passing that we think this serves to emphasise the importance of the uppermost air passages, especially the naso-pharynx, in connexion with the disease. It is very unlikely that the sphenoidal air cells became infected secondarily to the lungs. In some cases the total length of illness had been so short that, for so much purulent fluid to have been present in the sphenoidal air cells, infection in that region must have been present from the start. When the frequency and severity of epistaxis is remembered, as well as the tendency to otitis media already commented on, the importance of the naso-pharynx as a likely site from which the whole trouble starts can hardly be exaggerated. The practical issue of this surmise should be insistence on the simple antiseptic toilet of the nose and throat—by nasal douche and gargle—once a day or oftener both by healthy individuals exposed to the danger of infection, and by the influenza cases themselves at the earliest possible moment before they are too ill to gargle or to douche.

The bacteriology of the sinus infection is dealt with lower down.

TREATMENT.

Treatment of influenzal cases naturally divides itself into two categories—that directed to the general run of simple uncomplicated cases, and that which has been tried for the virulent septicæmic group.

Uncomplicated Cases.

The first group is readily dismissed. Although a large number of different remedies have been recommended and vaunted as "specific" for the early treatment of influenza, consideration of their application with controls upon a very large scale has encouraged us to doubt whether the course of the disease is modified or abated in the slightest degree by any one of them. And in this connexion we would like to add our gradually increasing conviction that although common sense naturally dictates the greatest reasonable precaution possible even for the mildest case, yet the virulent type appears to originate *ab initio* and to develop in spite of early treatment. We have been struck so frequently by the change in character of the mild into the virulent type in spite of every care in the early stage that the conclusion appears to us irresistible that development of the virulent type was unavoidable.

FIG. 1.—This illustrates an early case in which the facial colour is frankly red, and the patient might not appear ill were it not for the drooping of the upper eye-lids, giving a half-closed appearance to the eyes.

FIG. 2.—This illustrates a pronounced degree of the "heliotrope cyanosis." The patient is not in physical distress, but the prognosis is almost hopeless.

FIG. 3.—This illustrates another type of the cyanosis, in which the colour of the lips and ears arrests attention in contrast to the relative pallor of the face. The patient may yet live for twelve hours or more.

As a routine procedure every case was given calomel gr. iv. and mag. sulph. 3 ii. on the following morning. As "specific" remedies we employed ol. cinnamon, aspirin, quinine, and sod. salicylate, and our ultimate conclusion has been that although drugs at this stage are of value as symptomatic remedies no value attaches to their application either in cutting short the duration of a mild attack or in preventing its development into the more serious type.

Quinine merits a word of special reference, since its advantage as a prophylactic has been loudly acclaimed. Whilst it is impossible to declare that no defence whatever is produced by this drug, we can at least publish the experience of seeing eight cases in men who had for a month previous to their admission to hospital with influenza been taking 10 grains of quinine regularly every day for malaria.

Finally, we would add a warning that the attempt to belittle the condition and allow the patient to return to his ordinary duties after a short febrile period has been poor economy. In very many cases—we are speaking of the present epidemic, as distinguished from the cases in June, which took a much milder course—a recurrence has occurred on the third day after the patient has been allowed to rise; and we consider it highly necessary to insist on at least three afebrile days before the patient gets up at all, and then three clear days up and dressed with relative inactivity before he is permitted to return to his unit even for light duties.

Treatment of the Virulent Type of Case.

In the earlier cases reliance was placed upon (1) the employment of oxygen in the orthodox fashion; (2) the administration of cardiac stimulants; and (3) venesection.

It is convenient to consider *venesection* first. Notwithstanding the absence of right-sided cardiac dilatation, the blue appearance of the patient seemed analogous to that of a typical pneumonic case in which venesection was indicated, and suggested this form of treatment. In no case has venesection produced the slightest improvement, not merely in the patient's general condition, but even in the degree of cyanosis. Apart from other considerations, the act of venesection itself is unsatisfactory. The blood flows with great difficulty, and only with prolonged perseverance has it been possible to extract the quantity likely to be of any benefit; in fact, the absolute failure to ameliorate the condition induced the conclusion that mere venosity of the blood alone was not the cause of the colour, but that some change had taken place in the blood itself which prevented its taking up oxygen, as, for example, the formation of methæmoglobin or even of some other pigment which had destroyed its capacity for carrying oxygen. Such a conclusion has, however, been completely disproved by the absence of any characteristic bands in the spectrum, and also by our experiments upon the oxygen-carrying capacity of the blood, which showed in all cases a condition fully equal to the normal, and in a few cases, presumably owing to polycythæmia, actually surpassed normal controls. Similarly, the employment of oxygen in the routine fashion 10–15 minutes at a time failed to produce even temporary relief. Reference will be made later to the continuous administration of oxygen.

With the failure of venesection, *saline infusions* were next adopted as a routine procedure in all "blue" cases. Subcutaneous, or rather intramammary, introduction was found, with one curious exception (*vide infra*), to produce no improvement. On the principle that a more immediate effect might be produced by intravenous medication, this route was substituted for the subcutaneous method, but with no greater success. And, again, no more favourable report is possible in the case of the simultaneous processes of venesection and intravenous injections, which other observers have claimed to employ with satisfactory results.

With the failure of saline infusions, addition of various substances to the saline solution was instituted on more or less empirical lines. On the principle that "acidosis" was playing a part in the production of cyanosis sodium bicarbonate in various quantities was used, and later glucose in 1, 2, and even 4½ per cent. strengths of solution.

The specific treatment by Mulford's antipneumococcal serum, administered intravenously, was tried in a few cases only owing to the comparative difficulty of obtaining large quantities, but no results accrued to encourage its employment on a large scale.

And, indeed, however lamentable such an admission must be, we must place on record the conclusion that not one

single line of treatment can be credited with the capacity of saving one of the virulent cases. Certainly desperate cases recovered though few in number, and in not one of these cases was any special line of treatment adopted.

A striking instance was afforded by one particular case whose condition was so extremely grave as to appear hopeless, so much so that it was felt to be unfair to adopt any of the special methods of treatment which were on trial, for failure in this case could hardly be a reflection upon the adequacy of the treatment. And yet this case was one of the very few extreme cases which recovered.

Other Forms of Treatment.

It has been mentioned that one curious exception occurred in the treatment by subcutaneous saline injection. In this instance suppuration occurred at the site of inoculation with sloughing of the tissues and the formation of an abscess, in the pus of which were identified *Staphylococcus aureus* and a streptococcus morphologically resembling the organism recovered from the heart's blood in some of the fatal cases. The patient made a complete recovery, although a week previously his condition had appeared hopeless. On the principle of forming other "fixation abscesses" of this kind, intramammary saline infusions were then resumed in another series of cases, the idea being that injury to the tissues by distension with the fluid might lead to the same happy result as in the case referred to. Not a single case, however, responded in similar fashion, nor was any improvement otherwise obtained. In a more heroic attempt to encourage abscess formation a live culture of streptococci obtained from the heart's blood of a fatal case were injected in a dozen cases, the dose administered being estimated at 15 millions. In not a single case did any suggestion of suppuration appear at the site of inoculation, and of the 12 cases upon whom this treatment was tried 8 died. It only remains to be added that the four who recovered were severe but not desperate cases, and it cannot be supposed that the culture contributed in any way to their recovery, as dozens of similar cases recovered without such treatment. Injections of turpentine were also employed, but without any advantage.

On the presumption that want of oxygen was the cause of the cyanosis and presumably of death, the continuous administration of oxygen by the Haldane apparatus, similar to that employed in "gassed" cases, was then undertaken. It must be added that only a certain percentage of cases are suitable for this treatment which, as recommended by Professor Haldane, must be practically continuous for many hours. The patient must be sufficiently intelligent and *compos mentis* to understand the persuasion that it is necessary for him to tolerate any slight discomfort for the sake of the ultimate gain, and the application is impossible in the case of patients with pulmonary secretions which soon foul the apparatus. We cannot state that any real advantage arose from this method of treatment. A few patients admitted a certain temporary gain in comfort at the end of several hours, although ultimately death ensued; the majority resented its application altogether.

The stimulant employed as a routine procedure was brandy, 4 oz. in 24 hours being administered. Strychnine was found to be unsuitable. It appeared to excite the patients unnecessarily and increased delirium; and whilst of no value to the sufferer was the cause of much annoyance and distress to other patients by the noise produced.

Sedatives were also employed, principally bromide, bromide and chloral, tinct. opii and morphine hypodermically, but the last named alone appeared to have any value in producing sleep or quietening delirium. Paraldehyde has been more recently tried, but at the time of writing no definite conclusion in its favour can be stated.

Emetics were administered in a few cases in which, from the chest signs, expulsion of purulent material might have been expected. Large doses of vinum ipecac. and vinum antimoniale proved useless; emesis was induced by apomorphine hypodermically, but no relief could be noted.

We may perhaps anticipate one criticism of our attempts to treat the virulent cases under consideration. It may be argued that the value or otherwise of no line of treatment can be estimated by its application to moribund or desperate cases. This, of course, is perfectly true, but, as we have found reason elsewhere to mention, it is impossible to estimate the severity or the probable development of severity of a case; and to apply any line of treatment indiscriminately to all cases on the principle that some might be

prevented from developing into the virulent type would be a useless method of estimating the value of the treatment, since the large majority of cases which spontaneously recover would have to be credited to the particular treatment under consideration. It cannot be argued that any time was lost once the suspicion arose that a desperate case was to be anticipated, and since it is obviously impossible to quote actual statistics under this head, we can only express a conviction that so far as our observation extended nothing prevents the development of the serious case from one apparently trivial, and nothing can claim to avert the course of its virulence once it has developed.

PROGNOSIS.

This leads us to say a few words on the question of prognosis. The great majority of cases of influenza, of course, recover. What particular percentage comes into this category it is not possible to decide, since the 3800 or so cases admitted to the Connaught Hospital during the recent epidemic afford no indication as to the total number of cases in the Command, and the difficulty of obtaining figures sufficiently reliable to be of value has been insuperable. The comparatively mild cases are treated in large numbers at their own units, only those who are clearly from the outset of comparative severity or those in whom pyrexia has persisted for 48 hours are sent into hospital. We would once again indulge in the consolatory reflection that we are convinced that no untoward results must be attributed to the deprivation of early hospital treatment in all cases; neglect of any case is of course to be condemned, but again we would add that the virulent case appears to be something *sui generis*.

As regards the prognosis of the admittedly serious case, we must confess to having found difficulties in the establishment of criteria, even after an experience of many hundred cases. Early in the epidemic we were persuaded that the cyanosed cases invariably succumbed. Later we were fortunately able to record that a certain, even if a small, number of these recovered; and yet the latter have been quite indistinguishable from the majority of the cyanosed cases who died. No criteria as to temperature, pulse-rate, or respiration-rate, and not even of general condition, can be absolutely determined. It is true that a rapid fall in temperature without any amelioration of symptoms was in a "blue" case almost always a precursor of death within 24 hours, and that the case with blue colour, when accompanied by a cold, clammy skin, might be considered to be beyond hope of recovery. And yet cases whom earlier in the epidemic we considered to be beyond redemption certainly recovered, encouraging the determination not to abandon hope entirely until the patient was unmistakably moribund.

An even more painful indication of one's prognostic deficiency was afforded by cases who, not only at their admission but even for several days of treatment in hospital appeared to run a comparatively trivial course and to give rise to no legitimate anxiety, suddenly took a turn for the worse, rapidly developed cyanosis, and died within a few hours of being only trivially ill.

PROPHYLAXIS.

A few final words may be added on the question of prophylaxis. We cannot refer to the greater question of dealing with the prevention of the epidemic or of limiting its spread once it has appeared, for these are matters for the consideration of sanitary officers, both relating to troops and the general public. The precautions taken in the hospital itself were the ordering of a gargle as a routine procedure twice daily for all in attendance upon the patients and for those patients who had exhibited the disease to a comparatively mild degree. The solutions utilised were either pot. permanganate 1:4000 or tinct. iodine 1 drachm to the pint. In addition all medical officers, nurses, and orderlies were instructed to use a gauze mask around the nose and mouth whenever they were in attendance upon patients.

It may be added that not a single case developed in five special wards of the hospital devoted to tuberculous and neurasthenic cases, although these patients were from force of circumstances being visited by medical officers who were in attendance elsewhere upon influenza patients, and that in the large venereal division of the hospital only two or three sporadic cases appeared—these had apparently entered the hospital with the disease—who were immediately segregated,

and no instance of infection of other patients occurred. In the Detention Barracks at Aldershot, in which every patient occupies a separate cell in which he takes his meals, only coming into contact with his fellow inmates when he parades in the open air, not a single case developed. Incidentally, to complete the story, it must be added that the medical officer who visits these barracks daily is attached to the Connaught Hospital, and in addition to other duties has been in charge of influenzal patients.

PATHOLOGY.

This investigation was carried out with a view to establishing, if possible, the identity of the causal organism or organisms and their distribution in the body in cases of influenza. Furthermore, the work appeared profitable if it were only to establish or disprove the connexion between the present epidemic and what had previously been described under the term "purulent bronchitis."

The most striking feature of the results obtained is the frequency with which streptococci were isolated, while the *Bacillus influenzae* could not be demonstrated with equal constancy. These streptococci fell into two groups: (1) a long-chained streptococcus; (2) a small short-chained streptococcus exhibiting a preponderance of diplococcal forces. This latter organism appeared to have some claim to individuality and will be referred to as a "diplostreptococcus."

Before describing the organisms in detail the pathological and bacteriological findings will be considered.

Throat swabs.—The material was taken from the nasopharynx with a West swab and inoculated on to blood-agar.

| | Mild cases. | | | | | Severe cases. | | | | | Total. |
|-------------------------------|-------------|---|---|---|---|---------------|---|---|---|----|--------|
| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | |
| <i>Pneumococcus</i> ... | + | - | - | - | + | - | - | - | + | - | 3 |
| <i>M. catarrh. group</i> ... | + | + | + | + | + | + | + | + | + | + | 7 |
| <i>Strept. longus</i> ... | - | + | + | - | - | + | + | + | + | + | 7 |
| <i>Diplostreptococcus</i> ... | + | + | + | + | + | - | - | + | + | + | 7 |
| <i>B. influenzae</i> ... | - | + | + | + | - | - | - | - | + | + | 5 |

Profuse expectoration in these cases was uncommon, so that it was not possible to draw any conclusion from the small number of sputa examined.

Blood cultures.—Blood cultures were made in glucose broth in 10 cases shortly before death, but although several dilutions were tried only 1 case gave a positive result; the organism in this instance was the *Streptococcus longus*.

Urines.—Examinations gave the following results:—

| Cases. | Albumin % | Deposit. | Culture. |
|-----------------|-----------|--|------------|
| 1. Moribund ... | 0.02 | Granular and cellular casts. | No growth. |
| 2. " ... | 0.1 | No casts. Transitional epithelial cells. | " |
| 3. Severe ... | 0.5 | Transitional epithelial cells. | " |
| 4. " ... | 0.1 | Cellular casts and leucocytes. | " |
| 5. " ... | 0.4 | No casts. Transitional epithelial cells. | " |

It is remarkable that although in some cases casts were abundant, red blood-cells were not identified in the urinary deposit. Examination of the kidneys from these cases furnished no evidence of old-standing renal disease.

Leucocyte counts.—The following are the total leucocytes per c.mm. and the differential counts (P., polymorphonuclears; L., lymphocytes; L.M., large monocytes; E., eosinophiles):—

| Case. | Total. | P. | L. | L.M. | E. |
|---------------------------------|--------|-----|-----|------|----|
| 1. Severe ... | 6200 | 54% | 39% | 6% | 1% |
| 2. Moribund ... | 5890 | 68% | 26% | 5% | 1% |
| 3. Slight cyanosis... | 4650 | 44% | 47% | 7% | 2% |
| 4. Mild ... | 4960 | 66% | 30% | 3% | 1% |
| 5. Moribund ... | 4960 | 70% | 26% | 2% | 2% |
| 6. Bronchitis. Slight cyanosis. | 6820 | 86% | 11% | 2% | 1% |

In the last case bronchitis with purulent expectoration was present, which may account for the higher polymorphonuclear value, as compared with the other cases.

Cerebro-spinal fluid.—In two severe cases the fluid was clear, pressure normal; albumin (1) 0.006 per cent., (2) 0.0009 per cent.; cells normal; organisms negative; culture, no growth. In the absence of signs of meningitis or meningism this examination was not pursued to any

length, and the above results are typical of the total number investigated.

Oxygen capacity of blood.—This was in control case and four severe cases as follows (oxygen per 100 c.cm. of blood):—

| | | | | |
|----------------------------|----------------|----------------|----------------|------------|
| Control. | 1 | 2 | 3 | 4 |
| 18.5 c.cm. ... | 17.0 c.cm. ... | 20.5 c.cm. ... | 18.5 c.cm. ... | 18.0 c.cm. |
| Hæmoglobin = 105 per cent. | | | | |

These results were obtained by using Haldane's potassium ferricyanide method. It was not possible in the circumstances to estimate the blood carbon dioxide or alkali reserve. The absorption bands of methæmoglobin were not detected in the samples of blood examined.

Apparently the cyanosis in these cases may be attributed to the inadequate functioning of the pulmonary epithelium.

Bacteriological findings in post-mortem material.—The following organisms were found:—

| Material. | Number of cases. | Pneumococcus. | Diplo-streptococcus. | Strept. longus. | B. influenza. |
|-------------------|------------------|---------------|----------------------|-----------------|---------------|
| Heart blood... | 28 | 2 | 9 | 3 | 2 |
| Spleen | 28 | 1 | 2 | 3 | 0 |
| Lungs | 28 | 8 | 11 | 10 | 7 |
| Sphenoidal sinus. | 12 | 6 | 4 | 6 | 3 |
| Ethmoidal sinus.. | 5 | 3 | 2 | 0 | 2 |

Description of the Organisms Isolated.

The characteristics of the organisms isolated are given below.

The long-chained streptococcus grew well on all ordinary media, and on agar formed discrete pin-point colonies. On blood agar hemolysis occurred in all cases. No clot was formed in milk during three days' incubation, but acid was produced in lactose and glucose media.

The "diplostreptococcus" also grew well on all ordinary media. On agar the colonies were larger than those of the long-chained streptococcus and showed flattening of the surface and a spreading margin, which did not appear raised. Confluence of the colonies was seen in some cases. Hemolysis occurs to a slight extent.

Ancillary action of the *Staphylococcus pyogenes aureus* was very marked, resulting in increased size of the diplostreptococcal colonies.

A turbidity was usually formed in broth during the first 24 hours of incubation, but within three days flocculi settled to the bottom of the tube, leaving the supernatant fluid clear. The organism is Gram-positive, but in a few instances some members of a chain have failed to retain the Gram stain. Involution forms appeared in old cultures. A capsule was not demonstrated by Muir's staining method.

The pleomorphism exhibited by this organism is a striking feature: in 24 hours' pure culture on agar many diplococcal forms appear, together with short chains of coccoid individuals. After repeated subculture the streptococcal forms preponderate. The formation of chains does not appear to occur more readily in broth or other fluid media than on agar.

This organism has been found in pleural exudates during life and showed diplococcal and streptococcal forms, while pure cultures obtained from these fluids again gave evidence of pleomorphism.

The action on carbohydrate media has been uniform: acid is produced in glucose and a dense clot is formed in milk; there is no action on lactose, mannite, saccharose, or inulin, nor has gas been formed in any of the media used. The organism is not bile soluble. Agglutination reactions with antipneumococcus sera Types I., II., and III. were negative.

Four cultures from heart blood and two from the lung were inoculated subcutaneously into mice, but in no instance did death occur, nor was a local suppurative lesion produced.

In one case following subcutaneous saline injection abscess formation occurred, and it is interesting to record that the organisms isolated were the "diplostreptococcus" and the *Staphylococcus pyogenes aureus*.

The "diplostreptococcus" appears to resemble the *Streptococcus brevis*, although the latter is not usually regarded as pathogenic to man. Perhaps it would be best to use the name *Streptococcus brevis* generically; the "diplostreptococcus" could then be regarded as a species if its consistency of action and conformity of type could be established. In some respects the diplostreptococcus resembles the *Streptococcus viridans*, but the characteristic greenish hue of the colonies was not observed.

Gruber and Schüdel, and also Bernhardt and Meyer, have recently described a diplostreptococcus which occurred in the internal organs of cases examined post mortem. They regard this organism of decisive importance in the causation of acute pulmonary conditions and fatal complications of influenza.

Histology.

The histological findings in the lungs, kidneys, and liver are now briefly described.

The lungs.—In the majority of cases congestion and oedema were the most marked changes recognised in the post-mortem room, while a definite broncho-pneumonia was of less frequent occurrence.

In the former type of lung the alveoli contained a scanty fibrinous exudate with erythrocytes and polymorphonuclear leucocytes. The bronchial epithelium was thickened and proliferating, and leucocytic infiltration of the peribronchial tissue was present. Dilatation and

engorgement of the peribronchial blood-vessels was a marked feature. These appearances correspond with those seen at an early stage of broncho-pneumonia.

Sections examined from lungs at a later stage showed a confluent broncho-pneumonia. The alveoli were completely filled with sero-fibrinous material, in which numerous polymorphonuclear leucocytes and pigmented catarrhal cells were seen. The smaller bronchi contained masses of leucocytes and epithelial cells embedded in a sero-fibrinous matrix. In the more congested areas the alveolar septa in many places had given way and the exudate had become confluent.

The kidneys.—Cloudy swelling of the tubular epithelium was seen in some areas. The glomeruli were engorged with blood, and Bowman's capsule was thickened in most of the specimens examined. In a few instances a clear exudate was seen within the Malpighian bodies. There was no evidence of interstitial changes or endarteritis.

The liver.—The liver cells in the portal areas showed cloudy swelling and fatty degeneration. No cellular infiltration was evident in the tissues surrounding the portal vein. Amyloid change was not seen in the arterial zones.

SUMMARY.

1. The recent pandemic of influenza has included a large number of cases of septicæmia or toxæmia with a high degree of mortality.

2. These severe cases appear definitely related to the cases of "purulent bronchitis" which have been described as occurring in various parts of the country and in France. The essential feature is an infection by the *Bacillus influenza* with a secondary infection by some other organism. The existence of copious purulent expectoration is only an incident which may or may not be present and which has been singularly absent in the recent pandemic.

3. The secondary organism in question is the pneumococcus, *Streptococcus pyogenes longus*, or a "diplostreptococcus," the virulence of which appears to be exalted by the initial influenzal infection.

4. The characteristic features of the septicæmic type of case are variable lung symptoms, ranging from slight bronchitis to lobar pneumonia, very characteristic heliotrope lividity, dyspnoea, or rather polypnoea, and very rarely orthopnoea. These, with other so-called complications of influenza, such as pleurisy, nephritis, and others of lesser import, are evidence of the septicæmia or toxæmia referred to.

5. The relative frequency of the septicæmic type of case cannot be estimated with any degree of accuracy. The mortality of the septicæmic cases would appear to be as high as 90 per cent. at the beginning of an epidemic, falling to 50 per cent. at its termination.

6. Infection takes place in the upper respiratory passages, and involves the accessory nasal sinuses, where a septic sinusitis develops. From this and possibly other foci as yet undetermined, the toxæmia or septicæmia originates.

7. In view of the large number of instances in which the diplostreptococcus has been isolated in pure culture from the heart's blood and internal organs immediately after death, it is concluded that this organism plays an important rôle in the fatal cases.

8. The very large majority of cases of influenza run an uncomplicated course, terminating in from 3 to 14 days. No treatment has been found to be of any value in aborting an attack, or in preventing its development into the virulent type.

9. The large majority of cases of septicæmic type die in spite of any form of treatment. Cases have recovered who have been given no specific treatment of any kind.

We desire most gratefully to express our obligation to Major-General E. G. Browne, C.B., C.M.G., A.M.S., D.D.M.S., Aldershot Command, who has not only encouraged the undertaking of this investigation, but has often at great personal inconvenience assisted in the arrangements in various parts of his Command, arrangements which have placed at our disposal an enormous amount of material which would otherwise never have been seen.

Our thanks are also due to Lieutenant-Colonel W. Turner, C.M.G., R.A.M.C., O.C. Connaught Hospital, Aldershot, where the greater part of the investigation, clinical and pathological, has been performed. We are also greatly indebted to Colonel Robertson, C.A.M.C., O.C. Bramshott Military Hospital; Lieutenant-Colonel Cole, C.A.M.C., O.i/O., Medical Division, Bramshott Hospital; Lieutenant-Colonel J. Tidbury, O.C. Woking Military Hospital; and Captain Means, of the United States Medical Service, all of whom have generously placed at our disposal the patients under their command and care.

To the medical officers attached to the hospitals where investigations have been performed we offer a general expression of gratitude for their invaluable coöperation.

NOTE ON THE COMPARATIVE PATHOLOGY OF INFLUENZA.

By GEORGE R. MURRAY, M.D., D.O.L., F.R.C.P.,
TEMPORARY COLONEL, A.M.S.; PROFESSOR OF SYSTEMATIC MEDICINE IN
THE VICTORIA UNIVERSITY OF MANCHESTER; CONSULTING PHYSICIAN
TO THE ITALIAN EXPEDITIONARY FORCE.

THE comparative pathology of an infective disease is always interesting, and it has in many cases thrown light on the modes of infection in man. During the present pandemic of influenza I have not met with any reference to the occurrence of a similar malady in either domestic or wild animals. It is possible that some animals have been affected, and it would be of interest to ascertain if any localised epidemics of influenza in animals have been observed. The pulmonary complications, as seen this year in man, alike in England, France, and Italy, due to mixed infections of the respiratory organs, so closely resembled those observed in an epidemic in horses which came under my notice more than 20 years ago that a brief account of it may be of interest at the present time. I write entirely from memory, but the main features of the epidemic were as follows:—

A certain railway company had a number of valuable horses which were kept in large stables. Two long rows of stalls were arranged in each of the buildings, which were well ventilated and kept in excellent condition. Many of these horses were rapidly attacked by an acute illness with symptoms of nasal catarrh which was accompanied by a clear watery discharge from the nostrils. The majority of the horses made a good recovery, but some of them developed symptoms of acute pulmonary disease and died. Post-mortem examination by the veterinary surgeons in attendance showed that death was due to acute lobular pneumonia, complicated by pulmonary abscesses which developed in the areas of consolidated lung. A puzzling feature of the epidemic was the irregular distribution of the cases. The malady did not spread in sequence from stall to stall, but cases occurred at irregular distances from each other in the same stable.

As several valuable horses had died and the disease continued to spread, I was asked to investigate the cause of the epidemic and to give advice as to the most suitable means to be adopted in order to stop the further spread of the infection. On making a bacteriological examination I obtained from the nostrils of horses suffering from the acute nasal catarrh cultures of a small bacillus closely resembling, if not identical with, Pfeiffer's bacillus. The same bacillus was recovered from the patches of broncho-pneumonia in the lungs of a fatal case. In this case there were several abscesses which had formed in the consolidated areas of the lung. Cultures prepared from the pus in these abscesses yielded growths of *Staphylococcus albus*.

It therefore was evident that the disease was primarily an acute catarrhal infection of the respiratory passages closely resembling influenza in man. In some cases the same bacillus invaded the lung and broncho-pneumonia supervened. This was complicated by a secondary staphylococcal infection which caused a rapid breaking down of the consolidated lung and the formation of localised abscesses.

In human influenza the usual mode of spread appears to be by aerial convection of the infection to those in the immediate neighbourhood of the patient, as was so clearly shown by Major Michael Foster and Major Anstey Cookson in the case of a limited outbreak in a surgical ward.¹ In the epidemic in horses the irregular spread of the disease was apparently due to the use of dry moss litter as bedding, fine particles of which could be seen floating in the air when illuminated by a ray of sunlight. The nasal discharge from an infected horse dripped on to this bedding, where it dried and was carried to all parts of the stable by light currents of air.

The company was advised to remove all the moss-litter, and after thorough cleansing to wash out each stable with a disinfectant and to use sanitas sawdust as bedding. This was done in each stable while the horses were out at work, with the result that the epidemic ceased at once and no more horses were lost.

The chief points of interest in this epidemic were the resemblance of the disease to human influenza, the rapidly fatal results of the acute pulmonary complications caused by a double infection of the lung, and the part played by dust in increasing the range of aerial convection from one animal to another. The range of aerial convection in human influenza is usually short, but in the management of patients it is advisable to keep the air of the sick room as clean and as free from dust as possible, and to disinfect all handkerchiefs and spittoons just as in cases of open pulmonary tuberculosis.

¹ THE LANCET, 1918, II., 588.

B. MULTIFERMENTANS TENALBUS.

By JAMES L. STODDARD, M.D. MASS.,

CAPTAIN, M.O., U.S.A.

(From U.S.A. Base Hospital No. 5.)

THE bacillus described here was isolated from a case of gas gangrene of the arm which recovered promptly upon excision of infected muscle. An account of the characteristics of the bacillus has been undertaken because—

1. The bacillus appears to differ from the anaerobes described in the literature. (The references available include the report on anaerobes of the British Medical Research Committee, by Dr. James McIntosh, and the monographs of Captain H. G. M. Henry and of Weinberg and Seguin.)

2. At a certain stage the bacillus produces swollen and irregularly staining forms closely resembling the so-called "citrons" usually believed to be characteristic of *B. vibrio septique*.

3. Certain facts suggest that the bacillus may be of importance in symbiosis with *B. sporogenes* in producing local muscle infections. This is merely a possibility, however, and it seems on the whole most probable that the pathogenic importance is slight and of rare occurrence.

The author is greatly indebted to Dr. McIntosh for the serological reactions as well as for his confirmation of the impression that the bacillus differs from those described in his report.

CASE.—Pte. X. Patient received a perforating explosive wound of left forearm, with fracture of ulna. Excision of muscle for gas infection at C.O.S. Entered base hospital next day with localised gas infection of forearm. Immediate operation with excision of portions of flexor and extensor tendons, which were found gangrenous. No further evidence of gas infection.

Cultures.—A swab was taken at operation from the gangrenous muscle in the depths of the wound and planted in chopped meat medium.

Technique of isolation.—After growth for three days the culture was streaked on slants of Stelti's egg medium made with trypticised broth, and incubated in McIntosh and Fildes jars. This method has been found to give excellent and rapid growth of all anaerobes tried, including *B. edematis*.

Two sorts of colonies were immediately evident: (1) those typical of *B. sporogenes*; (2) very elevated, sharply defined, circular yellow colonies, turning white on the second or third day. Several of each of these two kinds of colonies were fixed where widely separated, emulsified (by shaking with sand in sterile salt solution), and replated separately. After apparently pure cultures were obtained, this immediate replating of isolated colonies was repeated several times. (The first attempt gave two colonies free from *B. sporogenes*, as tested by growing in chopped meat, thus indicating the efficiency of the plating method.) No other organisms than *B. sporogenes* and the bacillus were obtained. It is extremely improbable that *B. welchii*, at least, was overlooked, because the experiment was tried of planting *B. welchii* and this bacillus together in chopped meat and streaking on egg, and invariably *B. welchii* gave many times the number of colonies, which were easily distinguishable.

The cultural characters were as follows:—

Anaerobiosis.—There is no growth aerobically on slants. There is an extremely slight sediment in cultures planted in glucose bouillon which has been freshly shaken with air. The bacillus proves to be a fairly strict anaerobe.

Motility.—The bacillus is very actively motile in the condensation water of egg slant. In chopped meat its motility is less marked. It is actively motile in plain bouillon, but non-motile in glucose bouillon.

Proteolytic action.—There is no demonstrable proteolysis from putrefactive cultures grown on egg for long periods. Chopped meat shows no evidence of digestion. In milk the curd undergoes softening, but a diminution in volume is questionable. There is no blackening of meat or egg.

Saccharolytic action.—Glucose, lactose, saccharose, maltose, glycerol, inulin, raffinose, and salicin are fermented vigorously. There is no action on dulcitol or mannite.

Indol production.—No indol is produced.

Odour.—Faint and not characteristic. No special odour of butyric acid in milk cultures.

Hemolysis.—Surface colonies on blood agar produce a definite ring of hemolysis in 24 hours.

The gross appearance of cultures is described below.

Chopped meat. Within 24 hours gas is produced. There is no blackening or digestion of the meat even after long incubation, and no definite change in colour.

Glucose bouillon.—In 24 hours there is a heavy flocculent precipitate. The medium is slightly cloudy from small floating flecks. The flocculent precipitate is easily broken up by shaking but quickly settles out again. Gas is produced and appears throughout the culture when it is shaken (as in champagne).

Plain bouillon.—The medium is diffusely cloudy with a slight sediment, somewhat flocculent.

Milk.—The usual reaction in 24 hours is a thickening of the consistency, apparently from the precipitation of the casein, with the evolution of gas, which produces a coarsely bubbly foam $\frac{1}{2}$ in. to $\frac{1}{4}$ in. deep, over the surface. With further incubation the casein precipitates more completely, settles to the bottom, and leaves a cloudy fluid above.

With a heavy inoculation or under exceptionally good conditions a more vigorous reaction takes place, and in 24 or 48 hours the culture closely resembles the reaction with *B. welchii*. There may be a floating clot filled with bubbles. The clot is softer than with *B. welchii* and is easily broken up.

The nature of colonies is as follows:—

On glucose agar surface colonies in 24 hours appear greyish, 2-3 mm. in diameter, raised, with sharp edges and somewhat irregular outline. A hand-lens shows a clear translucent stratum in which float white flecks. The flecks are not definitely distinguishable by the naked eye. They form triangular or other straight-sided geometrical figures, and thus present a crystalline appearance.

In two days the colony appears whiter. The hand-lens shows more numerous flecks, which have increased in size. In some colonies the whole centre is opaque and white, shading gradually off to a clear translucent border.

In three days nearly the whole colony is a dense, opaque clear white with a narrow translucent rim, which may still show the crystal-like flecks, often arranged radially. The consistency is sticky, stringing out when picked, but not adhering to the agar.

As time goes on the colony grows, reaching a size of 5 mm. It heaps up so that it becomes quite thick, with rather steep sides. The edge is clear and sharp. The colour is opaque pure white.

Deep colonies on glucose agar are small, white, opaque, and irregular in shape. They are often lenticular, with a horn-like projection from one side, or reniform, with a projection from the "hilus." They are $\frac{1}{2}$ mm. in size. In two days they enlarge a little, there is a tendency to form large gas bubbles, which tear up the agar, giving a confluent growth about their periphery. Often the growth extends as a white film over the under surface of the agar.

On blood agar the surface colonies are smaller and more opaque at the start and do not show clearly the crystalline flecks. They tend to be flatter, not to increase in size, and to become level with the agar. They have a definite hemolytic zone.

Deep colonies on blood agar resemble in shape those on glucose agar, but gradually become a Vandyke brown, thus standing out sharply from the pale yellowish red agar.

Colonies on egg medium (whole egg and tryptic broth inspissated in slants).—In one day the colonies are 1-2½ mm., raised, yellow, with sharp, regular edge. They are very coherent and elastic, and adhere closely to the medium. A platinum loop may be rubbed with moderate pressure over a colony without affecting it visibly. If part is loosened and pulled away it stretches out, and finally snaps after it the rest of the colony in a mass. The second or third day the colony is larger, and is grey or white, with a narrow colourless or light yellow border. It is now sticky, but not so adherent or elastic.

The colony increases to a size of 4-6 mm. and to a thickness of 2-3 mm., and becomes a pure opaque white. There is never blackening or digestion of the egg.

The colonies on this medium are easily distinguishable from those of *B. welchii fallax vibron septique, oedematis, aero fetidus*, or any of the proteolytic group.

The morphology of the organism is next described.

The bacillus is more slender than *B. welchii*, and varies in length according to the conditions of the culture. (Fig. 1.) The short forms

FIG. 1.—Shows the bacilli, and the most typical forms occurring in the evolution of the spores. From a 24-hour colony of *B. multifementans tenalbus* on a trypt-egg slant. At A is drawn in for comparison a *B. welchii* from a similarly grown culture. Scale in microns.

tend to be slightly curved; the long forms usually show sinuous distortions. The ends are very rounded and occasionally almost conical. The bacillus resembles *B. vibron septique* in shape, but under the same conditions of culture has a larger proportion of short and swollen forms. It is Gram-positive in very young cultures, but quickly becomes Gram-negative in places or feebly Gram-positive throughout, and finally within 2-3 days, is usually Gram-negative. A one-day culture shows all variations from the Gram-positive to Gram-negative forms. The bacilli usually have a granular appearance and are feebly refractive. They do not appear as clear cut as *B. welchii* or *B. vibron septique*. There is no capsule.

Occasionally bacilli occur end to end, but long chains are not found. Long threads are produced on agar. There is no special grouping on slides, except in the case of the early sporulating forms, which tend strongly to stick together in dense masses.

The most striking feature is the rapid production of large numbers of swollen forms and spores. (Fig. 2.)

These are produced in greatest profusion in cultures on egg medium but occur in bouillon, in milk, or on agar.

Usually in forming the spore the bacillus swells centrally, with a gradual tapering off to the ends. At this stage it becomes Gram-negative and faint-staining, the process starting at the end which is to

FIG. 2.—Shows various swollen and irregularly staining forms, a long rod, and numerous Gram-negative bacilli. From a 3½ day colony of *B. multifementans tenalbus* on a trypt-egg slant. Scale in microns.

produce the spore. A deep-staining Gram-positive spherical mass appears at the opposite end. Soon after a large oval refractile sub-terminal spore appears, the remainder of the bacillus gradually fading out and disappearing. A 24-hour culture in milk usually shows practically no other forms but the swollen or sporulating bacilli. Numerous minor variations from this process occur. The bacillus may become pear-shaped or barrel-shaped, or may elongate. The spherical chromatic dots often appear at each end. The decolorisation often proceeds irregularly, leaving Gram-positive dots or bands. These forms resemble closely the corresponding stages of *B. vibron septique*. The swollen forms and spores, however, are produced in much greater profusion than in the case of the vibron, and are also produced earlier. A one-day culture on egg medium closely resembles a two- or three-day culture of *B. vibron septique* on the same medium. Occasionally sub-terminal or central spores develop quickly in a bacillus before it has swollen or become Gram-negative.

Serological reactions.—One bacillus is agglutinated neither by the serum of *B. vibron septique* nor *B. chauvæi*. For these findings I am under obligations to Dr. McIntosh, of the British Medical Research Committee.

Identity.—Since the bacillus appears to differ from those described in the literature it has been named, provisionally at least, *B. multifementans tenalbus*. The first name suggests the wide fermentative properties; the second an artificial condensed word compounded of the terms *tenax* and *albus*, the chief characteristics of the colonies.

Definite differences in colony characters, morphology, serological reactions, and pathogenicity distinguish it from *B. vibron septique*.

The bacillus differs from *B. II.* of Ghon and Sachs (1909) by complete absence of tendency to grow in long chains in liquid cultures, as well as in its fermentation reactions.

From *B. chauvæi* it is distinguished by its serological and fermentative reactions.

B. emphysematis maligni of Wicklein was a proteolytic organism.

From *B. welchii, oedematis, fallax, Hibler IX., butyricus*, and the proteolytic group the differences are obvious.

It appears to be closely related to, if not included in, the somewhat ill-defined group of motile fermenting anaerobes called by Grassberger "*saccharolyticus mobilis*."

Pathogenicity.—Experiments were carried out to determine the pathogenicity of the organism.

Technique.—The sites of injection were shaved and treated successively with alcohol, ether, and iodine. Unless otherwise stated, the cultures were grown 24 hours in 1 per cent. glucose bouillon and injected intramuscularly in the thigh. The culture of *B. sporogenes* was isolated from the case described above.

Protocols.—Rabbit I.: 2 c.cm. of *B. multifementans*. No evident effects.

Rabbit II.: 1½ c.cm. of *B. sporogenes*. No effects.

Rabbit III.: 1 c.cm. of *B. sporogenes* and 1 c.cm. of *B. multifementans*. Death in 20 hours. Autopsy.—Local muscle infection, confined to muscle group injected. Cultures of both organisms recovered from the muscle. H. +. Blood cultures negative.

Rabbit IV.: 9 minims of a 2-day chopped meat culture of *B. multifermentans*. No effects.
 Rabbit V.: 1 c.cm. of a 9-day meat culture of *B. multifermentans*. No effects.

Rabbit VI.: 1½ c.cm. of *B. sporogenes* + 1 c.cm. of *B. multifermentans*. Within 18 hours rabbit appeared sick, with marked local swelling and tenderness. Rapid recovery.

Rabbit VII.: 1½ c.cm. of a 36-hour culture planted with *B. sporogenes* and *B. multifermentans* together. No definite effects.

Guinea-pig I.: 1 c.cm. *B. sporogenes* + 1 c.cm. *B. multifermentans*. In 18 hours marked local swelling. Did not appear sick. Killed in 36 hours. Swelling still present. Autopsy.—Slight muscle infection of group injected.

Guinea-pig II.: 1 c.cm. of a culture planted simultaneously with *B. sporogenes* and *B. multifermentans*. In 20 hours moderate local swelling, still evident after 36 hours.

Rat 1.—3 minims 9-day meat culture *B. multifermentans*. No effects.

Summary of animal experiments.—There appeared to be a production of lesions with *B. sporogenes* and *B. multifermentans* in combination which were not produced with larger doses of either alone. In one case death was produced in 24 hours. The lesions, as a rule, appeared to be local, consisting in swelling and tenderness for a short period and in a muscle infection for one to three days.

B. multifermentans alone in moderate doses seems to be non-pathogenic; with *B. sporogenes* both become able to cross the threshold of the animal's resistance, but do not give extensive lesions.

These experiments were made a considerable time after both organisms had been isolated. Therefore they may not represent the true pathogenicity of the bacilli.

SPINAL ANÆSTHESIA.¹

By FELIX S. ROOD, M.B., B.S. DURH., M.R.C.S.,
 L.R.C.P.,

ASSISTANT ANÆSTHETIST, UNIVERSITY COLLEGE HOSPITAL, LONDON.

SPINAL anæsthesia has now been used in this country with increasing frequency for the last 10 or 12 years. It has, in spite of considerable opposition, attained a position as one of the recognised agents for producing anæsthesia. A large number of cases have been collected by various observers, and I think we may hope that the time has now been reached when a comparison of experiences may be of considerable use to us all in deciding the exact type of case in which this form of anæsthesia is most valuable.

It is not my intention in opening this discussion to enter into the technique of spinal anæsthesia, which is now very well known, but rather to speak of my own experiences of its use in a considerable number of cases.

I have always used stovaine except in about 250 cases in which novocaine was employed. After this trial I gave it up, because although novocaine produced perfect anæsthesia it does not produce a muscular relaxation equal to that produced by stovaine.

Effect of Density of Solution and Posture on Diffusion.

A 5 per cent. solution of stovaine, the density of which was increased by the addition of 5 per cent. of dextrose, was used in most cases. As this solution is heavier than the cerebro-spinal fluid the position and extent of the anæsthesia obtained with it can be regulated by the position of the patient during the injection. There is no doubt that although the stovaine-dextrose solution is diffusible its movements are controlled by gravity for a few minutes after injection. For instance, if a patient is placed upon his right side, with his pelvis slightly raised, so that there is a good steep slope from the third lumbar vertebra down to the mid-dorsal region, and the injection is made between the second and third lumbar vertebrae, this fluid will sink downwards in the spinal canal to the mid-dorsal region, producing an anæsthesia of the right half of the body before producing any effect upon the left side, and, moreover, if the patient is kept in this position for some few minutes before being turned on to his back the anæsthesia will be more complete on the right side—that is to say, it will extend higher on the right side than on the left and it will last longer on the right side. Muscular power will return first on the left side, and the patient will be able to move his left leg before he moves his right leg.

If immediately the stovaine has flowed to the mid-dorsal level the patient is turned upon his back it will flow across

the mid-line, and there will be practically no difference between its effects upon both sides of the body. Or, again, if the injection is given with the patient in the sitting posture the stovaine-dextrose solution will sink downwards in the theca and produce an anæsthesia which is more or less limited to the sacral plexus.

For young children I found that a dextrin-stovaine solution is less diffusible, and consequently the upper limit of the anæsthesia and muscular paralysis was more sharply defined, which is naturally a great advantage, as in the short spinal cords of young children the vital centres are not far removed from those parts of the cord in which it is necessary to produce anæsthesia.

In a few hundred cases a solution of stovaine in saline was employed. It was found that, irrespective of the position of the patient, the stovaine diffused about 10 in. upwards from the point of injection and equally on both sides of the body. It was with this solution impossible to limit its action or to increase it beyond this point except by increasing the dose, and then only very slightly. The anæsthesia produced by the saline-stovaine solution was found to be more transient than in those cases in which the denser solution was used and it was generally found necessary to employ almost double the dose of stovaine to produce equally long anæsthesia.

Position of Patient After Injection.

It might at this point be appropriate to say a few words in regard to the position of the patient after the introduction of the stovaine. I have already remarked that the dextrose and dextrin-stovaine solutions are mobile in the cerebro-spinal fluid for a few minutes after injection, but only for a few minutes, and we have never found it possible after about five minutes to increase the height of the anæsthesia even by very considerable elevation of the pelvis—that is to say, I think that the stovaine becomes fixed in from three to five minutes. It follows from this that the patient's head and the cervical region of the cord must be kept raised during injection and for the first few minutes afterwards.

In the early days of the use of spinal anæsthesia we were very careful to keep the head and shoulders of the patient raised not only during the injection but throughout the operation, and even in bed afterwards. This posture increased that tendency to syncope which is not at all uncommon. Latterly, after a few minutes, the patients have been allowed to lie quite flat, and we have found that this fall of blood pressure has been much less common and there have been no cases in which the stovaine has risen to a dangerous level.

Similarly, in regard to the use of the Trendelenburg position, it does not appear to be material whether the light or heavy solution is used. Generally I have employed the heavy solution, as I found that the analgesia lasted longer with a smaller dose of stovaine.

Combination with Other Methods of Anæsthesia.

When spinal anæsthesia was first employed the great merit claimed for it was that it did away with the necessity for general anæsthesia. But I think as time has passed and experience been gained that opinion has been very much modified, so much so that I think that all who have had any experience with this form of anæsthesia are agreed that the one great disadvantage of stovaine—the conscious patient, the patient present at his own operation—outweighed many of the advantages of spinal anæsthesia, and nowadays it is rarely employed without either some modification of "twilight sleep" or a little general anæsthetic. There is no doubt that a long operation in the Trendelenburg position or an operation on the rectum, such as a combined abdominal perineal or a Kraske's excision, are ordeals which few patients can face, even if it were to their advantage to do so.

Speaking generally, for severe operations the method which has been employed has been to produce anæsthesia with ether, then to inject the stovaine, discontinue the ether for a time, and then just to give a whiff to keep the patient unconscious.

For operations of a less severe type, such as hernia or appendicectomy, scopolamine and morphine are administered in the ward approximately an hour before the operation. The spinal injection is then given in the anæsthetic room before the patient reaches the operating table.

In this connexion I should like to mention a method for increasing the effect of scopolamine and morphine which was

¹ A paper read before the Section of Anæsthetics of the Royal Society of Medicine.

shown to me recently by Mr. P. P. Cole, and which I have used since with very great success. After the administration of the scopolamine and morphine the patient's ears are plugged with cotton-wool and the eyes covered with a bandage so as more or less to shut out the stimuli of light and sound. The increased effect of the scopolamine and morphine is most surprising, and many patients who have been treated in this way, although they have been lifted from the bed and carried upstairs, given an injection of stovaine and then been operated upon, have never known that they have left their room.

The Question of Safety.

It is important to gain some idea of the safety of spinal as compared with other methods of producing anaesthesia, as many of the indications for its use are relative and not absolute. Speaking from my own personal experience of about 8000 cases I have had two deaths.

One was a case of obstruction of the small intestine. The patient was very collapsed, there was profuse vomiting, and after the injection a flood of stercoraceous material from the mouth. The patient was apparently asphyxiated. The respiratory passages were found to be full of vomited matter at the post-mortem.

The second case was a child of 4 years, more or less moribund, suffering from a gangrenous intussusception. Death occurred during the operation from circulatory failure and not apparently from any interference with the respiration, which continued for a short time after any sign of cardiac activity could be observed. Apparently the fall of blood pressure caused by the stovaine, added to the shock already present, was sufficient to cause death.

I think that in the light of further experiences these were both instances of a mistaken choice of anaesthetic.

The above records include patients of all ages, from a few hours up to 80 years. The results obtained with young children were very satisfactory. Once the injection was given they generally passed into a somnolent condition and appeared to be in no way disturbed by the subsequent proceedings. The youngest infants were new-born babies suffering from imperforate anus and hernia into the umbilical cord. It is interesting to note that a relatively larger dose of stovaine is required to produce satisfactory anaesthesia in infants than in adults. A dose of 2.5 cg. of stovaine is required for the smallest babies and more for children of one or two years. Advanced age does not appear to be a contra-indication, and many of the patients included in this series were between 70 and 80 years. Elderly people are perhaps a little more liable to syncope if the anaesthesia reaches a high level.

Complications.

The complications met with during the course of the anaesthesia have been: (1) Interference with the respiration, owing to the stovaine reaching too high a level; (2) complications due to fall of general blood pressure, syncope, &c.; (3) vomiting.

Difficulties due to the stovaine reaching too high a level have been very rare, generally occurring in children where the margin of safety is so much less, or the patients have been fixed in some form of splint, or were in such pain that it was difficult to get a proper position of the spine before injection. Usually this complication was quickly relieved by a little oxygen. Two cases did definitely and progressively stop breathing as the stovaine ascended. One most instructive incident occurred.

The patient was a poor frail little boy who looked as if all his vitality had been sapped by the long strain of a suppurating tubercular hip. In spite of his condition amputation through the hip-joint was decided upon. Great difficulty was experienced in getting the child into a proper position for the injection. The stovaine undoubtedly reached too high a level. The immediate relief of pain following the injection was most striking.

Shortly after the commencement of the operation the intercostal muscles became paralysed. Then very shortly afterwards the diaphragm also—the child became intensely pale, lost consciousness and ceased to breathe. Very gentle artificial respiration by pressure with the hand on the front of the chest was performed, oxygen administered, and the operation hurriedly completed. These efforts at resuscitation had been continued for about five minutes when suddenly there was a slight movement of some of the muscles attached to the lower jaw, followed immediately by efforts at respiration, first by the diaphragm, next by the intercostals. Then, with startling rapidity, the child completely recovered. Before the last stitch had been put in the little patient volunteered the statement that he had been to sleep. No shock followed the operation and the child made an uninterrupted recovery.

The majority of difficulties met with were due to a fall of blood pressure, which varied from a slight pallor to a severe syncopal attack, with loss of consciousness and disappearance of the radial pulse. This complication was much more common in the earlier cases, before we realised that it was

not necessary to keep the head and shoulders raised continuously. Only three cases stopped breathing from syncope. The sequence of events was the same in each case—sudden pallor, loss of consciousness, a few gasping breaths, then cessation of respiration. These cases also occurred in the earlier days, when the patients were propped up. As we did not like to lower the head in order to treat this condition we raised the legs and pressed upon the abdomen. Recovery in each case was as sudden as the onset—one patient again remarking that he had been to sleep. A certain amount of pallor and fall of the general blood pressure occurred in about 30 per cent. of the earlier cases, but since the adoption of the recumbent position it has been much less frequent.

Vomiting occurring during the operation seems to be more or less dependent upon the height of the anaesthesia; if the anaesthesia involved the dorsal cord it was not uncommon, but very rare if the stovaine affected the lumbar and sacral plexuses only.

Without entering into the vexed question of the cause of the vomiting, whether it is subsequent to a fall of blood pressure and more or less mechanical in origin, or is due to direct absorption of the drug, I think experience has shown that measures directed towards raising the general blood pressure, such as slight Trendelenburg position, elevation of the legs, and pressure upon the abdomen, much relieve this symptom.

Sequelæ.

Another question of perhaps hardly less importance than that of immediate safety is whether spinal anaesthesia is more prone to be followed by serious and unpleasant sequelæ than other forms. This, of course, could only be answered by time. I think that the length of our experience now justifies the expression of certain impressions and some definite statements being made upon this point.

Headache, vomiting, and pulmonary complications have occasionally followed the administration of stovaine. Headache was not very common and then slight, but sometimes undoubtedly it was severe. My impression is that the headache was more common when the patients were conscious during the operation—that is, before a general anaesthetic or scopolamine and morphia were used in combination with the stovaine. It also seems that if the patients were handled very gently after the operation, and not jolted or shaken on the way back to bed, and kept quiet afterwards and not allowed to talk, they were less liable to this symptom. One or two cases of severe headache were almost instantly relieved by lumbar puncture and the withdrawal of about 20 c.cm. of cerebro-spinal fluid, although this fluid did not appear to be under any abnormal tension. Post-anaesthetic vomiting following stovaine was very rare and not prolonged in the few cases which did occur.

I think that there is evidence to show that spinal is much less frequently followed by pulmonary complications than any other method of anaesthesia. I have seen bronchitis and pneumonia both follow its use, as I have also seen these two complications follow after the use of local anaesthesia, and we must not forget that these are occasional complications in case of accidents, such as fractures, where no anaesthetic at all has ever been administered. It seems to me that respiratory complications under stovaine depended more upon the pathological conditions present, the condition of the patient, and the type of operation performed.

Acute septic conditions, as appendicitis and osteomyelitis, were generally present in those cases in which pneumonia followed the use of stovaine. Occasionally there were pulmonary complications after operations upon the upper abdomen which, I presume, were due to a reflex rigidity of the chest and insufficient expansion of the lungs, consequent upon the position of the abdominal incision.

Statistics Showing Absence of Permanent After-effects.

One of the difficulties which the pioneers of stovaine anaesthesia had to contend with was the suggestion that permanent muscular paralysis might follow its use, and from time to time cases in which there was some form of muscular paresis, loss of sphincter control, permanent anaesthesia, and even complete paraplegia have been reported.

I have been able to collect in all about 10,000 cases, of which I have actual personal knowledge. These include 400 cases which were done by the late Mr. A. E. Barker, which have not been published, but the records of which he gave to me, about 1500 or 1600 cases done at hospitals by the

resident officers, and about 8000 done by myself. In not one of these cases has there been any permanent paralysis of muscles or abolition of sensation, or any trophic lesions, with the exception of three cases of paralysis of the external rectus muscle of the eyeball, producing diplopia, which lasted about three weeks. Many of these cases were done by people with no special skill, but the same technique was more or less followed in all cases, so that I cannot help feeling that those cases of permanent after-effects which are reported occasionally may be due to some error of technique.

As far as I can gather, these permanent palsies have been more frequent when the puncture has been made very low down—viz., between the third and fourth lumbar vertebrae. Personally, I have generally made the injection between the eleventh and twelfth dorsal. It is generally easier, and if directly the needle has passed through the supraspinous and interspinous ligaments the stylet is removed and it is pushed gently, it is difficult to see how the cord can be damaged, as directly the meninges are entered cerebro-spinal fluid appears, and, moreover, the peculiar sensation imparted to the fingers as the meninges are punctured is quite characteristic, much resembling the puncture of tense tissue paper.

Indications for Spinal Anæsthesia.

It appears to me that the value of spinal anæsthesia is not, as I have previously remarked, that it abolishes the general anæsthetic. There are a few cases in which spinal anæsthesia presents great advantages over any form of general anæsthetic, such as in amputation or diabetic gangrene and for operations of emergency which cannot be done under local anæsthesia in patients suffering from acute respiratory diseases.

I have found spinal anæsthesia of special value for patients suffering from acute or chronic septic conditions with considerable toxæmia, such as acute appendicitis or osteomyelitis. Operations upon these cases are notoriously liable to be followed by disturbances of metabolism leading to a general acid intoxication and also to pulmonary complications.

I think that the general opinion of those who have used spinal anæsthesia to any extent is that the results are on the whole, better if general anæsthesia is not employed. Of course, as acidosis is already present in many of these patients before operation, and as the symptoms of acid intoxication following chloroform or ether (only very rarely after the latter) are much the same as those produced by septic absorption, it is only possible to express a general impression of the value of stovaine in these conditions after the experience of a considerable series. I think this is one of the points upon which we should much appreciate the opinion of our surgical friends.

But, undoubtedly, the great value of spinal anæsthesia is that it either abolishes or very much reduces the amount of shock associated with long surgical operations. This method of anæsthesia has been used nowadays extensively for many operations which are notoriously associated with shock, such as Wertheim's operation and various procedures for the removal of the rectum, and I think there is a general consensus of opinion that the results in these cases have been much improved.

Similarly, I think that the more severe operations in young children, such as excisions and amputations, especially at the hip-joint, are much less formidable under spinal anæsthesia.

Lastly, stovaine produces absolute muscular relaxation. This, of course, much facilitates the performance of many operations and renders long-continued and forcible retraction unnecessary. I do not think that it is overstating the case to say that there are some operations, such as the radical cure of a large and irreducible hernia in a fat and muscular subject, which would be hardly possible without its use. The slightest muscular rigidity makes the operation of prostatectomy very difficult. The complete muscular relaxation of spinal anæsthesia renders such great assistance that this operation is not often undertaken nowadays without its aid. Further, the amount of general anæsthetic necessary to produce muscular relaxation is very different to the amount necessary to produce loss of consciousness, so that by means of stovaine it is possible with a minimum of general anæsthetic to produce narcosis and complete muscular relaxation.

Contra-indications.

Perhaps almost more important than the indications for the use of spinal anæsthesia are the contra-indications against its use. I think these may be very shortly summed up if we say that spinal anæsthesia should never be administered to patients who are likely, from their condition, to be seriously affected by the fall of blood pressure, which is so often associated with the use of stovaine.

I believe that the experience of most operators in the military hospitals in France has been in accord with our experience in the civil hospitals at home, that spinal anæsthesia is absolutely dangerous for patients suffering from profound shock, and I believe that in most cases after a short trial it was given up. Of course, in the base hospitals there has been more scope for its use, as the conditions more or less approximate those of civil hospitals, and severe operations are undertaken upon patients who are in comparatively good condition at the time. Therefore, it seems to me that it should be clearly emphasised that spinal anæsthesia protects patients from the onset of shock due to severe and prolonged surgical procedures, but should never be administered to patients who are suffering from shock at the time.

I think that the impression that spinal anæsthesia is a substitute, when the patient is supposed to be too bad to stand a general anæsthetic, has been responsible for many of the reported fatalities. It is difficult to generalise as to the position of spinal anæsthesia in heart disease; in mitral disease with much pulmonary congestion it is sometimes very useful, but certainly never in aortic disease, nor in any other cardiac or vascular condition in which the patients are prone to syncope.

A problem which has often to be decided is whether the dangers associated with an immediate fall of blood pressure outweigh the benefit to be obtained from stovaine. This is especially the case in acute abdominal surgery. Here the advantages of stovaine are well known—the muscular relaxation, the ease with which the whole abdomen can be explored and the consequent shortening of the operation, and the diminution of the shock, which is so often associated with manipulation of the intestines. But if the patient is much shocked and almost in *extremis* from long-continued obstruction, stovaine should be used only with the greatest caution. Each case of intestinal obstruction must be judged upon its own merits; some of the most brilliant results of spinal anæsthesia have been obtained in this field of surgery, but I think that a routine practice of using this method for all cases of intestinal obstruction, irrespective of the condition of the patient, is only courting disaster.

Conclusion.

Finally, I should like to say a word in regard to the use of stovaine in hospitals as one of the routine methods of producing anæsthesia—I mean in those cases in which no definite indication for its use exists, but where anæsthesia merely is required for such operations as appendectomy, hernia, varicose veins, and so on. It is obviously an advantage to gain experience of this method so that when those cases do occur, in which the special indications for its use are apparent, it is not in the nature of an experiment. It has been urged against this view that spinal anæsthesia is not so safe as general anæsthesia, but I do not think that, given the ordinary care and skill, the facts warrant this conclusion. I have never seen a death from spinal anæsthesia administered for any simple operation, and I believe that many lives have been saved by its use, when occasion requires, and if it is one of the methods in daily use it is more likely to be selected and skilfully administered.

So that, I think, we may say that spinal anæsthesia is now long past the experimental stage. It is one of the recognised means of producing anæsthesia. It is not a universal anæsthetic to be applied to all cases. It has its special dangers. It has its special merits, but used in its proper sphere it is a very valuable method of producing surgical anæsthesia.

Clarence Gate Gardens, N.W.

ROYAL FREE HOSPITAL FAIR.—The League of Nations Fair, held on Dec. 3rd and 4th at 16, Carlton House-terrace by permission of Lady Cowdray, resulted in a sum of £2500 for the Royal Free Hospital.

INFANTILE SCURVY:

THE ANTISCORBUTIC FACTOR OF LEMON JUICE IN TREATMENT.

BY A. HARDEN, F.R.S.,

HEAD OF THE BIOCHEMICAL DEPARTMENT, LISTER INSTITUTE;

SYLVESTER S. ZILVA, PH.D., M.Sc.,

ASSISTANT, LISTER INSTITUTE;

AND

G. F. STILL, M.D., F.R.O.P.,

PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT OSMOND-STREET.

Lemon juice has long been recognised as a powerful antiscorbutic. It has recently been demonstrated by Harden and Zilva (1918)¹ that, after removal of the free citric and other acids from lemon juice, the residue retains antiscorbutic activity. As far as can be detected by the methods now available for the quantitative estimation of antiscorbutic potency, the main, if not the entire, antiscorbutic potency of the juice is retained by this residue, which is slightly acid to litmus, but can be made neutral if desired without vitiating its potency, and contains about 15 mg. of solids per c.c.m. The method of preparation has been described elsewhere.¹ Experiment on animals has shown that with precautions as to the temperature used this preparation can be concentrated in bulk to any desired volume, or even evaporated down almost to dryness without losing its potency as an antiscorbutic.

Application of Experimental Findings in Treatment.

The application of these experimental findings to the treatment of human beings is of more than academic importance.

The treatment of infantile scurvy, thanks to the clinical and pathological observations of Sir Thomas Barlow and the late Dr. W. B. Cheadle, has long been highly satisfactory in its results, albeit empirical in its origin, but the rapidity of relief and cure has depended upon the quantity of certain foods of recognised antiscorbutic value which could be administered, and this quantity has necessarily been determined chiefly by the toleration of the patient. In the case of infants this imposes considerable limitation, for the articles chiefly used are orange juice, grape juice, and powdered potato beaten up with milk. Digestive disturbance, particularly diarrhoea, is apt to occur unless these are used with caution. The antiscorbutic potency of such foods cannot, therefore, be utilised to its full extent.

It was hoped that this difficulty might be overcome by the above mentioned preparation, on the assumption that the almost complete elimination of the acids from the fruit juice would remove or diminish its irritant property, and that the concentration of bulk would make it possible to give much larger quantities of the antiscorbutic factor than has hitherto been practicable. This preparation was therefore used in the treatment of the following four cases of infantile scurvy.

Notes of Cases.

In the first case to be recorded, a severe one, rapid recovery ensued.

CASE 1.—Male infant aged 7 months. Had been fed on sterilised "humanised" milk from birth until the present time; the juice of one orange was given once a week until the child was 5 months old, but not subsequently. At 4 months he cut two teeth and at 5 months two more, when the gums were first noticed to be swollen; a fortnight later the gums bled easily. At 6½ months he began to scream as if in pain when moved; the pain seemed to be in the legs.

On admission to hospital the upper gums were greatly swollen, dark purple, and fungating, projecting almost between the lips. The edge of the central incisors could just be seen almost buried in the swollen, projecting gums. The legs were motionless, except for movement of ankles and toes; some thickening of lower third of right femur and over corresponding part of left femur. Both legs seemed very painful to touch. There was some recent hæmorrhage into vaccination scars; urine contained red blood cells.

The infant was put upon a diet of undiluted boiled milk, which clinical experience has shown to have no curative effect on scurvy. One ounce of the concentrated preparation equivalent to double the bulk of original lemon juice was given three times a day, i.e., the equivalent of about 4 lemons daily. After 3 doses, about 18 hours after treatment was begun, there was "some improvement; not so distressed when bed is approached and is moving legs a little." After 4 doses, 25 hours after treatment was begun, "obviously better, moving both legs, especially the left, which is less swollen, the fungating upper gums project less and the teeth are less buried than yesterday." The dose was then increased to 1½ oz. of this concentrated preparation for 2 doses and then to ½ oz. of a much more concentrated

preparation = 7 times the bulk of lemon juice, so that the child has the equivalent of 6½ lemons daily. After two doses of the former and one of the latter, 48 hours after treatment was begun, the protrusion of the gums was less, the legs were moved much more freely, and the tenderness was "much diminished"; the child's colour was also improved.

The solution was continued 5½ days altogether; the child took in the first 24 hours the equivalent of 7½ lemons, in the next 24 hours the equivalent of 6½ lemons, in the next = nearly 9 lemons, next = 12 lemons, and next = 8 lemons.

The recovery was very rapid; 72 hours after treatment began all swelling had gone from the thighs, the legs were moved normally, and there was no pain. The gums were much less swollen and the blood had disappeared from the urine. After 5½ days the solution was stopped, the child being well except for slight swelling of the gums (which 2 days later became normal in colour and showed very little swelling).

The child had taken in 5 days the equivalent of the juice of 42½ lemons without the slightest disturbance of digestion.

In stopping the solution, 2 teaspoonfuls of grape juice were given three times daily, and the stools at once became too frequent 5 days. In contrast to the normal 1-3 per diem whilst taking the much more potent antiscorbutic preparation.

Case 2 was one of mild scurvy, with much less severe symptoms than in the preceding case, but the rapidity of the cure was none the less striking.

CASE 2.—Male infant aged 10 months. Was breast-fed two weeks, then on Glaxo for one month, and since then fed only on a mixed food, apparently a preparation of dried milk with malted cereal. For two weeks before admission began to cry as if with pain whenever the legs were touched. On admission he lay with legs flexed at hips and abducted; did not move them and seemed tender over lower ends of thighs, where perhaps slight thickening, but very vague. One tooth just showing, but gums normal.

The child was put on a diet of undiluted boiled milk. One and a half ounces of the concentrated preparation, equivalent to twice the bulk of lemon juice, were given three times daily. The first dose was given at 7 P.M., the second at 2 A.M. on the following day, the third at 10 A.M. Shortly after this the tenderness was found to have disappeared and there was more movement of the legs. Two and a half hours after the fourth dose—i.e., 28½ hours after treatment was begun—there was no tenderness and the child was moving the legs well, though not vigorously. The next day, after six doses, it was noticed that the child "looked much better." The legs were moved well. There was no looseness of the bowels, though the equivalent of 12 lemons was taken in 38 hours.

The solution was continued regularly in doses of 1½ oz. of the double strength until the infant had taken the equivalent of 18 lemons in 72 hours, after which only a few doses at irregular intervals were given, although really unnecessary, as the child was already well.

In the next case also there was rapid recovery.

CASE 3.—Male infant aged 8½ months. Fed on Savory and Moore's food prepared in the usual way with milk and water since 3 weeks old. For the last three weeks has cried when lifted, as if his legs hurt him. When first seen he did not move either leg, and was evidently afraid of being touched. No definite periosteal thickening could be detected. There were three teeth, but the gums were normal.

This case was seen in private consultation. No accurate record of the progress was obtainable, but on 1½ oz. doses of the concentrated preparation, = twice the bulk of lemon juice, there was a very rapid recovery.

Case 4 was one of severe scurvy, with much more subperiosteal hæmorrhage than was present in any of the three previous cases.

CASE 4. Female infant aged 11½ months. After the age of about 3½ months was fed on Savory and Moore's food for nearly 5 months, and then on Allen and Burry's No. 3 food prepared with pasteurised milk 3 parts, barley water 1 part. At about 10 months old some swelling of lower ends of tibiae and then just above wrists was noticed; the child seemed in much pain. At 11 months there was some blood in stools; more recently a large bruise-like mark had appeared over right buttock.

When the child was first seen there was over both femora and tibiae, especially the left, marked thickening with acute tenderness. There was no movement of either leg or thigh, except very slight flexion and extension of ankles. The gums were swollen and purple.

The child was put upon a diet of undiluted boiled milk. The concentrated preparation = twice the bulk of lemon juice was given, and after 2 doses the infant seemed "much brighter and happier." It was continued in doses of 1½ oz. three times daily, and 48 hours later, after 6 doses, the child was seen again. The child's colour was noticeably better; she had also laughed and made baby sounds for the first time that day for many days. There was more movement of ankles and toes, the gums were less swollen and less purple. The thickening over left femur was decidedly less, but that over left tibia was rather increased.

The child was next seen 5 days later, when the right leg was actually being kicked about freely; the left leg showed some motion, but only very little. The thickening over the left tibia and femur was still present, but much less; the gums were now only "purplish."

Eight days later the left leg could be moved and 5 days after this the infant was able to enjoy its bath, moving both legs almost normally, though the swelling in the left did not finally disappear until about 26 days after treatment began.

This last case was one in which there was evident a large amount of subperiosteal hæmorrhage, and, according to the history, this was probably of some weeks' duration, so that recovery of movement and disappearance of swelling was necessarily a slower process than in the other cases where the thickening, and therefore presumably the subperiosteal hæmorrhage, was much less in degree; the

¹ Harden and Zilva (1918), *Biochemical J.*, xii., 259.

improvement, however, as compared with other cases of similar severity treated by the ordinary methods, was undoubtedly unusually rapid.

Value of the Treatment.

The outstanding feature of this treatment was the use for the first time clinically of the antiscorbutic factor separated from the greater part of the inactive components of the foodstuff in which it occurs. Moreover, this antiscorbutic factor was given in concentration at least double—in one case seven times—as strong as that in which it occurs naturally in the foodstuff (lemon) from which it was obtained. The treatment was thus, so to speak, “intensive.”

As was hoped, the result was found to be extremely rapid amelioration of the symptoms. It is very difficult to give any accurate comparison between the results obtained and those which come from the ordinary treatment hitherto adopted, whether with “potato cream” (i.e., powdered cooked potato beaten up with milk) or orange juice or grape juice. No two cases of scurvy can be guaranteed to be of exactly the same severity; moreover, the effectiveness of the ordinary treatment has often been diminished by insufficiency of dose, and unless the maximum quantity which could be tolerated has been given it would be unfair to assume that the maximum effectiveness of such antiscorbutics has been demonstrated. Owing, however, to their tendency to cause looseness of the bowels these foods cannot be increased beyond certain limits, which vary with the particular infant. Even within these limits the results of their administration are so striking and rapid that it might have been thought hardly possible to improve on them; one of us (G. F. S.) has elsewhere mentioned that “under efficient antiscorbutic diet the tenderness and pain on movement is usually appreciably less in 48 hours.” With the use of the concentrated preparation of the antiscorbutic factor the improvement is even more rapid.

Consideration of Results.

In Case 1, which was severe, there was noticeable improvement—viz., diminution of distress and increased movement of legs about 18 hours after treatment was begun. In Case 2, a slight case, there was definite improvement in these respects in about 16 hours, and very marked improvement in 26½ hours. In Case 3, a very severe case, there was “a great change”—viz., diminution of distress within 22 hours.

This increased rapidity of improvement is not due to anything new in the essential element of the treatment, which is the so-called “antiscorbutic factor”; this was the curative principle in the ordinary antiscorbutic diet just as much as in the preparation we have used. The difference is that in the experimental preparation the unessential and irritant part of the foodstuff has been eliminated and the antiscorbutic factor left in an aqueous medium, associated with little extraneous matter, and this even when considerably concentrated seems to have no irritating effect upon the stomach or bowels. In this way it is possible to give quantities of the “antiscorbutic factor”—e.g., the equivalent of the juice of 6–12 lemons daily—which, if given in the ordinary form of potato or fruit juice, would set up very severe gastro-intestinal disturbance. In ultimate completeness of cure this mode of treatment offers no advantage over the ordinary antiscorbutic foods which only more slowly secure an equally satisfactory result, but it is no small matter if we can hasten even by a few hours the relief of the very acute distress caused by infantile scurvy.

The above results bring out another point of theoretical interest—namely, that they confirm the results obtained experimentally in animals. This antiscorbutic preparation was first tested by Harden and Zilva (1918) in the prevention of the disease in guinea-pigs and curatively in a monkey suffering from scurvy. The clinical course of the recovery in the infants described above was almost identical with that observed in the monkey, and there can now be little doubt as to the bearing results obtained in experimental scurvy with monkeys and guinea-pigs have on human scurvy.

MEDICAL APPOINTMENTS IN IRELAND DURING DEMOBILISATION.—The Local Government Board have intimated to the Omagh guardians that they will not sanction a permanent appointment of a doctor to a dispensary district until after demobilisation. As a result the proposal to fill up the Gortin Dispensary has had to be abandoned and the guardians decided to make a temporary selection.

HYSTERICAL VOMITING IN SOLDIERS.

By W. R. REYNELL, M.A., M.D. OXON., M.R.C.P.,

CAPTAIN, R.A.M.C.

(From the Seale Hayne Military Hospital, Newton Abbot.)

HYSTERICAL vomiting is comparatively common among soldiers. It is surprising how scanty are the references to this symptom in the very large literature on war neuroses. Besides being a most distressing condition in itself, it may lead to a severe degree of neurasthenia, with progressive emaciation and increasing mental distress, the loss of appetite with which it is associated finally leading in severe cases to a condition of anorexia nervosa. In many cases it is the only symptom, but the slighter forms of hysterical vomiting are common among patients suffering from all kinds of war neuroses. In a large number of cases which have come under our care the hysterical nature of the disorder has apparently not been recognised, and the patient has been diagnosed and treated as a sufferer from gastritis. From the only paper I have seen dealing with hysterical vomiting in soldiers, it would appear that the condition is usually very resistant to treatment and that a complete cure can rarely be expected in less than several weeks or months. Such has not been our experience at Seale Hayne Military Hospital. Out of some 600 cases of war neuroses admitted between June and October, 1918, 18 have suffered from hysterical vomiting of from four to twelve months' duration. All of these patients have been cured within three weeks of admission, most of them within ten days, and a few after a single treatment.

Etiology and Pathogenesis.

Hysterical vomiting is the perpetuation by suggestion of a symptom due in the first place to a pathological condition, such as that caused by gassing, dysentery, phthisis, or appendicitis. In a certain number of cases the exciting cause is purely emotional.

1. *Gassing.*—Gassing is the most frequent exciting cause of hysterical vomiting in soldiers. When a man is gassed, saliva is secreted abundantly as a result of a protective reflex, and when swallowed it carries in solution enough of the irritant to set up acute gastritis with frequent vomiting. The existence of acute gastritis in such cases has been proved by post-mortem examination of fatal cases. In the large majority of cases the inflammation of the gastric mucosa and the vomiting subside *pari passu* within a few days and at most within two or three weeks. In the predisposed neuropath or in a soldier, whose suggestibility has become exaggerated as a result of war strain, the vomiting may persist as an hysterical symptom after the organic disturbance which gave rise to it has disappeared, in the same way as aphonia and blepharospasm, which are the other common hysterical sequels of gassing.

2. *Infections and intoxications.*—In a number of cases the onset of the vomiting dates from an attack of dysentery, trench fever, and other infections. Post-mortem examinations have demonstrated the existence of a definite gastritis in bacillary dysentery, and perpetuation of the vomiting occurs in a certain proportion of patients in the same way as in gassing.

Hysterical vomiting following dysentery.—Pte. D., aged 29, a baker's assistant in civil life, had always been delicate and inclined to be nervous and excitable. He enlisted in September, 1914. After being in India for over two years he was transferred to Palestine in April, 1917. He was beginning to feel very run down as a result of malaria and a “touch of the sun,” when in June, 1917, he contracted dysentery. Vomiting occurred from the onset of the dysentery, and persisted to a slight extent after he left hospital. A few weeks later it became worse and he had to be readmitted. On admission to Seale Hayne Hospital in August, 1918, the patient stated that he had vomited after food for the past 14 months with the exception of short periods when the sickness had not been sufficient to incapacitate him and he had rejoined his unit. For the last three and a half months he had vomited three or four times a day. His weight was 8 st. 9 lb. 3½ st. less than on enlistment. Treatment was begun the day after admission to hospital; the vomiting at once became less frequent, and within ten days it had ceased entirely. There has been no relapse in the six weeks which have since elapsed.

Hysterical vomiting following trench fever.—Pte. P., aged 29, accountant, always suffered from “nerves and headache.” He had a nervous breakdown in 1912. He enlisted in July, 1916, and went to France in December, 1917. He was admitted into hospital in January with a severe attack of trench fever, for which he was kept in bed for four months. After he had been ill some weeks he began to suffer from sickness after food; he could retain nothing but small quantities of

peptonised milk. For several weeks he was treated by rectal feeding, but even then he was sick three or four times a day. On admission to Seale Hayne Hospital in July, 1918, he was in an extremely emaciated and depressed condition.

Treatment was begun at once, and a stomach-tube was passed once a day for a week. After the fifth day the patient vomited once a day, and at the end of a fortnight the sickness had ceased completely. There was no relapse, and when the patient was discharged from the Army three months later he was able to go back to his civilian work immediately.

Captain J. W. Moore has recently had under his care a case of hysterical vomiting following an anæsthetic, and he has kindly furnished me with the following notes of the case.

Hysterical vomiting following surgical anæsthesia.—Pte. B., aged 34, manager of a dairy in civil life, has never been robust or able to do hard work. His brother suffers from neurasthenia and has never been able to work. He was called up in March, 1917, and was sent to France the same month. He was classified B2 on account of his general weakness, and only did orderly work. A week after his arrival in France a shell burst near his hut and a piece of metal entered his buttock. He was operated on two days later and a piece of shell was removed. After the operation he vomited constantly for several days, and since then he had been unable to take any solid food without vomiting.

On admission in July, 1918, he was emaciated and weak, and it was with great difficulty that he was persuaded to eat solid food. Repeated explanations of his condition and constant encouragement were successful in stopping the vomiting 10 days after admission. There was no relapse and he was discharged seven weeks later completely cured.

3. *Reflex vomiting.*—Among the causes of reflex vomiting, which may be perpetuated and exaggerated as hysterical vomiting, phthisis and appendicitis are comparatively common.

Hysterical vomiting in phthisis.—Pte. B., aged 40, was admitted for "gastritis" on May 1st, 1918. He had vomited after every meal for more than 12 months. He was emaciated and looked very ill. Examination of his chest showed extensive tuberculous changes, but the condition was now one of smouldering activity with an evening pyrexia of 99° to 99.6° F. The patient was kept in bed until his temperature was normal. His vomiting was treated as if it were hysterical, and within ten days it had ceased completely and no relapse occurred. He rapidly gained in weight and was discharged from the Army in a satisfactory condition, not having vomited for two months.

4. *Emotional vomiting.*—In the genesis of all neuroses emotion is a factor of prime importance, and in a number of cases of hysterical vomiting this was the exciting cause. Thus a soldier was detailed to bury some decomposed German corpses. The work was of such a revolting nature that he was sick, and the vomiting continued for several months until, when the origin and nature of his illness were explained to him, he was able to control the habit.

Symptoms.

In most cases the patient vomits after every meal, but sometimes vomiting only takes place once or twice a day. In slighter cases several days may pass without sickness, and in such patients the vomiting can often be traced to slight emotional upsets, such as fits of temper, a disturbed night with nightmares, bad news, or sudden excitements. One of my patients, who had not vomited for three weeks, was sick twice after being moved from one ward to another, but after this there was no relapse. Sudden active movements, such as running, lifting, or even stooping to lace up boots, may be enough to cause sickness.

The vomiting is often preceded by epigastric pain, which is always relieved when the patient has been sick. Some patients are sick almost immediately after food. Others are only sick after an interval of half an hour or more. One patient of mine never vomited during the day, but was sick every night two or three hours after going to bed, four or five hours after his last meal. Water-brash is a common precursor of the actual vomiting; patients complain of a "rifting up," "repeating," and a feeling that their stomach contents are being "churned up."

A characteristic feature of hysterical vomiting is its independence of diet. Sometimes, however, a patient can take liquids but not solids. In others some particular article of diet, such as meat or potatoes, will always cause vomiting. But in severe cases sickness occurs when anything solid or liquid is swallowed, and I have had several patients who have been fed exclusively by the rectum for weeks without cessation of the vomiting. If the vomit be examined it will be found to consist of undigested or partly digested food, but the quantity is less than the amount of the meal last taken. It is often watery in character and may contain but little solid matter.

Examination of the patient reveals no sign of organic disease; some epigastric tenderness may be present, but this is unusual.

If the vomiting is of long standing, wasting may be considerable, and many of my patients had lost several stones in weight, but the loss of weight is rarely such as would be

compatible with organic disease of the same duration. If a barium meal be given and an X ray examination made, the size, shape, and movements of the stomach are found to be normal, and it is emptied at the normal rate, if vomiting does not take place.

Diagnosis.

The diagnosis is not usually difficult. It depends upon the absence of signs of organic disease, often with a characteristic history of the onset following gassing or emotional stress. Independence of diet is typical of hysterical vomiting, and as a rule the variety of diets that have been tried is in marked contrast with the monotonous regularity of the vomiting. The watery character of the vomit and the absence of pain both point to a functional disorder. In doubtful cases a barium and X-ray examination may be made, but this is rarely necessary.

The following case is instructive, and illustrates how important it is to be on the look-out for a slight organic focus of irritation in cases which do not recover completely under treatment.

Hysterical vomiting associated with reflex vomiting, due to dysenteric appendicitis.—Pte. M., aged 30, contracted dysentery in Egypt in November, 1917. During his illness he vomited ten or twelve times a day. He was transferred to England in March, 1918, still vomiting three or four times a day. On May 13th he was admitted to Seale Hayne in an emaciated condition. He said that he had never vomited less than three times a day during the last eight months. He was very weak and depressed, and had lost 3 st. in weight.

Examination revealed no sign of organic disease, and the condition was diagnosed as hysterical. Treatment was successful in reducing the vomiting to once a day, with occasional days in which the patient was not sick at all, but a complete cure could not be obtained.

Some weeks after admission the patient complained of a slight pain in the right iliac fossa. Examination showed definite though slight tenderness in this region and Bastedo's inflation test was positive. Appendicitis was diagnosed and the patient was transferred for operation. He was not sick after the anæsthetic and has been completely free from vomiting since, a period of six weeks.

It is quite evident that this patient suffered from chronic appendicitis, which, though insufficient to cause definite symptoms until it became acute, was enough to give rise to a habit of vomiting which was very largely hysterical in nature, as it was very greatly improved by psycho-therapy.

Prognosis.

A certain number of cases of hysterical vomiting recover spontaneously without treatment, but in a large proportion the symptom persists indefinitely unless suitable treatment is given. Elaborate dieting, drug-therapy, and especially rectal feeding, do more harm than good by confirming the patient in his belief that there is something serious the matter with his stomach. I know of one case in which a gastro-enterostomy had been done as the patient was supposed to have a duodenal ulcer as a result of gassing, but the natural consequence of performing such an operation on a normal stomach was to aggravate the vomiting and make it less amenable to psycho-therapy.

Treatment.

The method of treatment I have used for nearly all my patients with hysterical vomiting has consisted of psycho-therapy, reinforced by the suggestive effect of the passage of a stomach-tube. The patient is interviewed in a private room the day following his admission to hospital. A full history of the illness is taken and a thorough physical examination is made. In some of the earlier cases an X ray examination was carried out. The patient must be made to feel that his case has been thoroughly investigated and is thoroughly understood.

The origin of the hysterical symptoms is now fully explained to him. He is told that his illness began with a definite inflammation of the stomach, but that the inflammation subsided within a few weeks; at the end of that time the complex act of vomiting, which would be almost impossible to carry out by a normal person, had become very easy for him, so that what he is now suffering from is a habit. His stomach has acquired the bad habit of contracting soon after it has been distended with food, and all that is necessary is to break this habit. It is explained that a stomach-tube will be passed before his meals, and that this will cause retching and a contraction of the stomach, so that the organ will be given the exercise that it has grown used to about meal-times, but that having contracted before meals it will not have the same tendency to do so after meals. The explanation is, of course, not to be regarded as a scientific one, but simply as one which will appeal to the patient's mind. I tell him that it is a method of treatment that I have never known fail, and that it will depend on him how often the tube need be passed, as in many previous cases a single treatment has stopped the vomiting completely. I impress upon the patient particularly the importance of breaking the habit immediately, as much trouble will be saved thereby. In order to make his effort successful at once I

order that his first meal shall be dry, no fluid of any kind being taken for two hours after meals, which should consist at first of toast and butter and an egg. As soon as the patient can retain dry light meals the diet is gradually increased until a full diet can be taken. After that fluids are allowed with meals, beginning with small quantities. The vomiting becomes less frequent at once and usually ceases at the end of a week or ten days; in favourable cases it should stop after the first treatment.

In patients of superior intelligence it has often been possible to effect a rapid cure by pure psycho-therapy without the aid of suggestion. The patient is made to understand his condition exactly, and is told that in men of more than average intelligence success usually follows such an explanation, but that, failing that, a method of treatment is available which never fails, though it is somewhat unpleasant, and will therefore not be used unless it is absolutely necessary.

Note on Hysterical Vomiting of Civil Practice.

There is no doubt that many cases of chronic vomiting met with in civil practice are hysterical in nature, although this is not usually recognised. It is probable, though further research will be necessary to establish the fact, that most, if not all, cases of so called pernicious vomiting of pregnancy are purely hysterical, the accompanying acidosis being the result and not the cause of the vomiting. The following case is one of several seen by Lieut.-Colonel A. F. Hurst.

Hysterical (so-called pernicious) vomiting of pregnancy cured by psycho-therapy.—A patient, 21 years old, in her first pregnancy suffered during the first few weeks from the vomiting which is so common as to be regarded as physiological. Instead of ceasing, however, at the usual time, it continued in an aggravated form, so that by the third month she was quite unable to retain any solid food. When first seen by Lieut.-Colonel Hurst, at the end of the fifth month, she had become extremely emaciated and weak. She vomited fluids as well as solids, and during the last three weeks she had been fed by rectum, but the vomiting returned directly anything was taken by mouth as well as independently of this. Her urine contained diacetic acid and acetone, and a trace of albumin; her breath smelled of acetone. As all drug treatment had failed, the gynaecologist who saw her at the same consultation urged immediate emptying of the uterus. Lieut.-Colonel Hurst asked for 24 hours' delay. He explained to the patient how her symptoms had arisen as a habit, maintained after the normal vomiting during the first weeks of pregnancy had ceased, and how after its long rest her stomach could now deal with ordinary diet in spite of its failure with slops and fluids, which were not the normal food of an adult. She was thoroughly convinced, took a good luncheon, tea, and dinner the same day, and never vomited again. The signs of intoxication, which were simply the result of starvation, rapidly disappeared, and she was delivered of a healthy boy at full term. She had gained so much in strength that she was able to nurse him, and had lived a normal life during the last three months of pregnancy.

It seems probable that many cases of persistent vomiting after operations are purely hysterical, and the well-known efficacy of gastric lavage in such cases may be more the action of suggestion than due to the removal of mucus or other irritant from the stomach. On several occasions patients, who have suffered so severely from vomiting after previous anaesthetics that they have only been persuaded with difficulty to undergo a further operation, have not vomited at all when told convincingly that the anaesthetist, who was going to give them ether on this occasion, had a special method which was certain to prevent vomiting, although it was quite indifferent what special modification he used.

In the same way the vomiting associated with gastritis, gastric ulcer, chlorotic anaemia, and appendicitis may in suggestible individuals continue or recur as the result of auto-suggestion after the original cause has disappeared, as Lieut.-Colonel Hurst has pointed out. In all such cases it can be rapidly cured by pure psycho-therapy.

Dr. Vermeylen, a Belgian physician who has been for the past three years house surgeon at the North Devon Infirmary, Barnstaple, was recently presented with a cheque to defray his expenses of returning to Belgium by the committee of the institution. The gift was accompanied with a resolution expressing appreciation of his services. The medical staff presented Dr. Vermeylen with a case of surgical instruments.

THE LATE DR. J. MICHELL CLARKE.—As a memorial to the late Dr. Michell Clarke it has been decided to enlarge and continually to add to the medical library controlled by the Bristol University and the Bristol Medical-Chirurgical Society. The cost of the scheme is estimated at about £2000. The subscription list will shortly be closed. Mr. Rafter, registrar of Bristol University, is acting as honorary treasurer, and donations should be forwarded to him.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

FRACTURE-DISLOCATION OF ASTRAGALUS, WITH POSTERIOR DISPLACEMENT OF SUPERIOR FRAGMENT.

BY H. C. ORRIN, F.R.C.S. EDIN.

THE following case appears of sufficient interest and rarity to merit record.

Patient, private, aged 46, came under my care in hospital within seven days of his injury in France, and was said to be suffering from a "swollen and contused right ankle." During a bomb raid he was rendered unconscious, but thinks he was struck on the ankle by a flying missile. So severe, however, was the injury sustained that doubts have arisen as to whether he was hit direct on the ankle or, the foot being fixed, his body was laterally forced away from his foot by the bursting of the bomb. Personally I incline to the latter view.

On examination upon arrival here, there was marked swelling and ecchymosis of the right calf, inner side of foot, ankle, and tarsal region. No movement whatever could be elicited at the tibio-astragaloid articulation. Through the

Fracture dislocation of astragalus.

oedematous tissue on the inner side of ankle could be felt a bony mass, situated laterally between posterior aspect of internal malleolus and tendo Achillis. At a later date, when the swelling had subsided, this mass could be defined as hemispherical in shape. Stereoscopic X ray plates were taken, and the injury was found to be one of fracture of the astragalus, with posterior dislocation and displacement of upper half on to superior surface of os calcis.

Operative measures were not undertaken until all swelling and ecchymosis had subsided. I then investigated the condition by making an incision on inner side of ankle, between internal malleolus and tendo Achillis, and through which I removed the fractured and dislocated half of the astragalus. When the bone was fully exposed, its position was still more remarkable, for not only had a fracture-dislocation occurred, but in its displacement backwards the upper half was found rotated on itself, so that its superior articular surface was looking inwards. No tendons or important structures were divided in the operation, and the wound was closed without drainage. Healing was by first intention.

Passive movements and massage were commenced early, and when ten weeks later the patient walked out of hospital his range of movement at the ankle-joint was most remarkable.

A PERMANENT CRITERION FOR THE STANDARD AGGLUTINATION TEST.

BY A. D. GARDNER, D.M. OXON., F.R.C.S.
(From the Department of Pathology, University of Oxford,
Standards Laboratory.)

ONE of the difficulties in obtaining absolutely uniform results with the macroscopic agglutination test (Dreyer's technique) lies in the fact that different observers may adopt different degrees of agglutination as "standard agglutination." In the directions sent out with standard agglutinable cultures this is defined as "marked agglutination, without sedimentation." But a considerable range of size of flocculi is covered by this definition, and it is desirable, if possible, to introduce greater uniformity in this section of the technique. Even a single experienced worker cannot always keep in his mind's eye precisely the degree of flocculation that he is accustomed to take as "standard," though his error from this cause will be small. The divergence of the standards of any two observers, however, may give rise to discrepancies in the calculation of standard agglutinin units amounting to 20 per cent. or more.

A satisfactory way of overcoming this difficulty would be found in the issue from the central laboratory of permanent tubes showing the precise degree of flocculation that is best adopted as standard agglutination for the various types of bacilli.

The writer has found a way of preparing such tubes in the following manner:—

Tubes.—Special agglutination tubes are made double the length of the small agglutination tubes used in Dreyer's method, but of the same calibre.

Gelatin Solution.—A 20 per cent. solution of gelatin in normal salt solution. This is used for diluting the serum. It must be made as clear as water.

Culture.—Standard agglutinable culture of the bacillus to be agglutinated.

A suitable dilution of the specific serum is made with the melted gelatin solution. One c.c.m. of Oxford standard serum mixed with 9 c.c.m. of gelatin solution answers well. Ten drops of this are thoroughly mixed with 15 drops of standard culture in each tube, and the tubes are incubated until the desired degree of agglutination appears. Then the tubes are immediately stood in cold water and one small drop of commercial formalin is added to each. Such tubes as show, on further minute inspection, the precise degree of agglutination desired are sealed off in the blow-pipe flame. The formalin fixes the gelatin, which will not again melt even at boiling temperature.

Thus we have a tube presenting all the appearances of an ordinary agglutination tube with the agglutinated fluid contents, but actually containing a solid and permanent block of fixed gelatin. I have observed no alteration in the appearance of these tubes over a period of six months or more. If desired, a series of such tubes may be made showing every degree of agglutination from total to the finest trace. A series of this kind may be very useful for reference in fine experimental work.

Different emulsions of the same organism may present variations in the quality of agglutination they show. And particularly in the case of *B. paratyphosus A* and *B. typhosus* are found to agglutinate somewhat imperfectly. Standard agglutination tubes ought, theoretically, to be prepared for each species of bacillus, but for practical purposes it is quite sufficient to use one species of a group as type for the whole group—e.g., *B. typhosus* for the "enteric" group of bacilli and *B. dysenteriae* (Shiga) for the dysentery group. "Standard" agglutination of the latter group is finer than that of the former.

Oxford.

A CASE OF TRAUMATIC ANEURYSM OF THE EXTERNAL CAROTID.

BY S. C. DYKE, M.B., B.CH. OXON.,
CAPTAIN, R.A.M.C. (T.O.).

THE following case seems to show several points of surgical interest:—

Private —, age 34, was wounded by a bullet on August 8th. Bullet entered on left side of nose, just below the root, passed through upper part of nasal cavity, across right side of face, and made its exit through the right external auditory meatus.

On August 13th he was admitted to a hospital in England. He then had little pain. Entrance and exit wounds were both clean; there was considerable swelling of right side of face, over parotid region, and apparently limited by the parotid fascia. This swelling showed no signs of inflammation, and was ascribed to extravasated blood. X rays showed some fragments of bullet casing in right parotid region and a fracture of the right ascending ramus of inferior maxilla. There was some paresis over distribution of upper branch of right facial nerve. This had disappeared by August 21st.

On August 22nd patient complained of much pain in right side of face, and on examination it was found that the parotid swelling was now pulsatile. A diagnosis of traumatic aneurysm was made, though whether of internal or external carotid it was impossible to say.

The patient was seen by Major Cecil Bevers, R.A.M.C. (T.F.), who decided, in view of the impossibility of learning by other means, to expose the carotid and determine by occlusion of the vessels whether the external or internal carotid was involved. Further, in view of the manifest difficulties in the way of performing distal ligation on a vessel lying in the midst of a large extravasation of blood deep in the parotid gland, it was decided to try the effect of proximal ligation of the affected vessel.

Operation was performed the following day. The carotid was exposed through usual incision. The operation was rendered difficult by the shortness of patient's neck, the bifurcation of the carotid being right up under the angle of the jaw. It was found that pulsation of the swelling was completely stopped by occlusion of external carotid; this vessel was accordingly ligated immediately above bifurcation. The establishment of a collateral circulation through the branches of the external carotid of the other side, as feared, did not occur. The swelling decreased in size immediately after operation, and 10 days later, except for the fracture of jaw, condition of patient was normal.

The case is of interest as showing the successful result of early proximal ligation in traumatic aneurysm, even of a vessel forming such free anastomoses as the external carotid. The successful result was probably due to the rapid development of the aneurysm, which outran the widening of the anastomosing vessels and gave no time for the formation of a collateral circulation. In an aneurysm of slower growth the result would probably have been different.

Medical Societies.

SOCIÉTÉ DE BIOLOGIE, PARIS.

THE following is a summary of some of the papers read at the meetings of the society held on Dec. 16th and 21st:—

P. CARNOT.—The Question of Antiseptics.

1°. Antiseptisme des milieux extérieurs: la dose et la spécificité des antiseptiques, la production des formes de résistances du microbe: sporulation, etc. sont des notions importantes à acquérir. Une même espèce microbienne peut se comporter différemment vis à vis d'un même antiseptique suivant la dose. Lors du passage dans l'économie, il peut y avoir augmentation de résistance aux antiseptiques et accoutumance à cet antiseptique. Avec une dose d'antiseptique inférieure à la dose mortelle, on peut obtenir une action antiseptique seulement. C'est l'action atténuante d'antiseptique. En diminuant les doses l'antiseptique devient accélérant. A dose minuscule l'action se poursuit. La question des relations des propriétés physicochimiques et des propriétés antiseptiques est complexe: les phénomènes de dissociation, d'ionisation, de solubilisation ont un rôle complexe à jouer. L'action du milieu extérieur, électrolyte, protéine, cellules vivantes du milieu, est importante et modifie considérablement l'influence des antiseptiques. 2°. Au début de la guerre, l'aseptisme chirurgical dominait. Puis l'antiseptisme a dominé. Beaucoup de chirurgiens la considéraient comme nulle, la discussion reste ouverte. La stérilisation des plaies semble ne réussir que d'une façon précoce et dans de bonnes conditions: méthode Carrel. Sur les suppurations anciennes aucune substance ne semble avoir l'action. L'action curative se fera d'autant plus sentir que le contact avec le germe sera plus prolongé et plus intime. Action sur la plaie: (1°) Antiseptique à action antibiotique générale sur microbe et cellules. (2°) Action antitoxique peu intense. (3°) Action antiseptique de plus en plus spécifique mais ayant un rôle empêchant indirect sur l'organisme: action exsudative, lymphorée, &c. 3°. *Antiseptisme interne.* Antiseptisme des canaux et des cavités: on cherche à porter directement l'antiseptique faible au contact du germe à combattre. Dans les infections générales, on emploie des substances à action antiseptique indirecte.

A series of papers followed on the action of particular antiseptics:—

PHILARDRAU.—Sodium Fluoride.

A. LATARJET and Mlle. FROMSY.—Antiseptic Action of Ionisation.

E. FOURNEAU and E. DONARD.—Chlorides of Iodine.

W. MESTREZAT and Th. CASALIS.—Monochloride of Iodine.

W. MESTREZAT.—Chlor-alum.

OL. REGAUD.—Artificial Serum under Pressure.

MAURICE CAZIN and Mme. S. KRONGOLD-VINAVER.—
Electivity of Antiseptics for Particular Organisms.

LOUIS BAZY and FAURE-FREMIET.—Wound Zones
Accessible to Antiseptics.

PLULB and FAURE-FREMIET.—Paraffined Dressings.

GATE and DECHOSAL.—Vaccination against Influenzal
Complications.

Résultats fournis par 105 recherches portant sur 82 cas de grippe, dont 37 sévères et compliqués. 1°. Le B. de Pfeiffer s'est montré une seule fois dans les crachats. 2°. Le pneumocoque fréquent dans les crachats a été trouvé 5 fois seulement dans des pus pleuraux au début, de l'épidémie, jamais dans le sang. 3°. Le *Streptococcus hemolyticus* a été vu 18 fois dans les crachats, 12 fois dans des pus pleuraux, 4 fois dans les hémocultures. Très virulent pour l'homme (6 décès sur 12 pleurésies, 3 sur 4 septiciémies). Ce streptocoque a montré peu de virulence pour le lapin. 4°. Des essais peu nombreux de vaccination curative anti-streptococcique ont paru donner des résultats assez nets, quand il s'est agi de gripes compliquées de streptocoques.

MERY and GIRARD.—Action of Antiseptics on Virulent
Germs in the Naso-pharynx.

Chez trois enfants porteurs de pneumocoques, virulents pour la souris, dans le rhino-pharynx, le collargol au 1/100 et l'huile goménolée au 1/10, versés par les narines largement dans le cavum pendant plusieurs jours de suite, n'ont réussi qu'à diminuer le nombre des colonies microbiennes ensemencées avec le mucus sur boîtes de Petri, sans atténuer la virulence des germes, notamment du pneumocoque, qui demeure virulent pour la souris.

POMMAY-MICHAUX, B. MICHAUX and MOUTIER.—A Diplo-
coccus Occurring in the Hæmocultures of Influenzal Cases.

Dans vingt quatre, les hémocultures de grippés ont décelé un diplo-coccus prenant le Gram, poussant lentement en milieux ordinaires, très bien en milieux à l'ascite, qui rappelle les caractères morphologiques du pneumocoque, mais qui n'est pas pathogène pour les animaux usuels de laboratoire (souris, cobaye, et lapin).

BRUNTZ and SPILLMANN.—Trench Feet a Vitamine
Deficiency.

Le manque de vitamines entraîne des troubles scorbutiques ou névritiques. Ces accidents suffisent pour expliquer le mal des tranchées, qui de ce fait peut-être considéré comme une avitaminose.

NORTH OF ENGLAND OBSTETRICAL AND GYNECO-
LOGICAL SOCIETY.—A meeting of this society was held in Liverpool on Dec. 13th, Mr. Miles Philips, of Sheffield, the President, being in the chair.—Mr. W. W. King showed Two Cystic Tumours of the Vulva of somewhat doubtful pathology. The first was probably a cystic adenoma of Bartholin's gland, and the other a cystic endothelioma.—Dr. Blair Bell showed an Abscess in a Fibromyoma undergoing Red Degeneration, and Encephaloid Cancer of Abdominal Wall secondary to paracarcinoma abdominalis for ascites due to intra-abdominal carcinoma.—Dr. J. H. Willett showed a case of Ectopic Gestation in which the mole, about the size of a hen's egg, was lying in the pouch of Douglas, and both Fallopian tubes apparently normal, except that on the right side a salpingotomy had been done some years previously, and this was found to be closed. He also showed a specimen of a Uterus with a large number of fibroids, in which there was an early pregnancy, in which hysterectomy had been necessary on account of severe pain.—Dr. Leith Murray showed a specimen of Sessile Red Fibroid weighing one pound on the anterior wall of the uterus, causing acute symptoms during pregnancy and enucleated at the twenty-first week without interruption of gestation.—Dr. Fletcher Shaw read the notes of a case of Extra-uterine Pregnancy which had progressed to the fifth month, and for which he had had to do an abdominal section on account of severe pain.—Dr. Briggs read a short note on the Radical Cure of Complete Proctentia, illustrating his paper with diagrams and photographs and reading the notes of several illustrative cases.

NATIONAL FOOD REFORM ASSOCIATION.—"Dietaries Suitable for Secondary Schools, Colleges, Hostels, Clubs, &c., with Recipes, Notes, Quantities, and Weekly Expenditure. Approximately, 8s. per head," 1s. 3d. net, is about to be published by the National Food Reform Association, Danes Inn House, 265, Strand, W.C. 2.

LIVINGSTONE COLLEGE, LEYTON.—This college, which normally exists for the training of men who are, or intend to be, foreign missionaries in an elementary knowledge of medicine and surgery, has been used since August, 1915, as a hospital for wounded soldiers. In a little over three years more than 2000 patients have been received from the Bethnal Green Military Hospital to which Livingstone College is an auxiliary. It has now been decided, temporarily, to close the institution, and it is hoped that the ordinary work of the college will be resumed next October. In the meantime the Hospital Council are appealing for funds in order that they may be able to hand over their accounts to the college with no deficit. About £300 is required.

Reviews and Notices of Books.

A *Text-book of Pharmacology and Therapeutics*. By A. R. CUSHNY, M.A., M.D., LL.D., F.R.S. Seventh edition, thoroughly revised. London: J. and A. Churchill. 1918. Pp. 712. 18s. net.

IN revising his text-book for its seventh edition Professor Cushny has not found it necessary to introduce modifications so extensive as those which distinguished the sixth edition from its predecessors. The classification of drugs—adopted in the sixth edition—on the basis of the organs most characteristically affected by them has justified itself, and is retained. Only closer study of the new edition reveals how much has been done, by deft re-statement here and addition there, to ensure that the book keeps pace with the progress of knowledge and continues to justify its reputation as a storehouse of practically all that is of proven significance in pharmacology.

The immediate need for this new edition was created by the issue of the Ninth Revision of the United States Pharmacopœia. The inclusion in this of biological standards for certain remedies necessitated a short chapter on methods of biological assay. This chapter goes hardly at all beyond description of the methods thus rendered official in America; and such a restriction was probably almost inevitable, for the sake of the American student, to whom a discussion of unauthorised methods might have proved confusing. More than one opinion is possible, however, concerning the validity of some of the methods adopted by the U.S.P., and the optimist may look forward to the possibility that before another new edition of the text-book is required a more progressive spirit among those responsible for such matters in this country will have widened the scope of this chapter. Only those who have tried for themselves to cope with it can form any estimate of the vast crop of pharmacological and therapeutic observation to be gathered in the world's medical and scientific literature, or of the extent to which it is scattered through journals devoted to the neighbouring sciences of physiology, chemistry, pathology, and practical medicine. The attempt at gleaming over these immense fields, to say nothing of the threshing and winnowing, means bewilderment for most of us. Professor Cushny's power of surveying a wide range of the literature, not only of avowed pharmacology but of the kindred sciences as well, of seizing instinctively what is new and significant among so much which is neither, and of presenting it in the light of his ripe experience as teacher and investigator, has given to his book the position of unique authority which it has long held among text-books of pharmacology in the English language.

Pharmacology, as an independent science, is a comparative novelty in the medical curricula of this country. The gradual displacement of the medley of *materia medica*, pharmacy, and clinical empiricism, with odds and ends of toxicology, which at one time took its name and its rightful place; the growing recognition of experimental pharmacology as the necessary basis of the scientific therapeutics which all desire—no changes have had more importance than these in the recent developments of medical education and practice. No influence has been stronger in promoting this change, and its logical outcome in the transference of exact methods to the clinical study of therapeutic effects, than that exercised by this text-book and by its distinguished author. It is to be hoped that more and more students will make it their teacher and guide. They may gain from it not merely equipment for examination tests, but a habit of mind which will be a lasting possession, an insight into methods which will enable them in turn to use their opportunities of practice for the advancement of medical science, as well as for the immediate benefit of their patients.

The Practice of Medicine. By SIR FREDERICK TAYLOR, Bart., President of the Royal College of Physicians. Eleventh edition. London: J. and A. Churchill. 1918. Pp. 1091. 24s.

IT is a high and arduous task to supply the needs of the average medical student for a systematic text-book of internal medicine during a period of 23 years, but Sir Frederick Taylor has done it. The first edition of the "Practice of

Medicine" appeared in 1890; the eleventh edition is now before us. During this period most one-man text-books have become systems with a number of contributors, and it is now recognised to be impossible for any one man to cover adequately and equally the whole ground of internal medicine. It may be that no other will attempt it. But in that case the fortunate student of the future will still have one cause of regret, for a one-volume one-author text-book gives a bird's-eye view of a subject which is obtainable in no other way.

Sir Frederick Taylor has added to the present edition short paragraphs on the new diseases, or new aspects of diseases, arising during the war. A certain number of new charts and illustrations also appear; but their selection is arbitrary, and it is doubtful whether 85 blocks are of any real value in illustrating so enormous a field. The lecture diagram, the ward, and the clinical laboratory are the proper illustrations to a book on the practice of medicine.

A few verbal errors have, as is natural, crept into the text, but on the whole the book is a marvel of accuracy.

Orthopædic Treatment of Gunshot Injuries. By LEO MAYER, A.M., M.D., Instructor in Orthopædic Surgery, New York Post-Graduate Medical School and Hospital. Illustrated. London and Philadelphia: W. B. Saunders Company. 1918. Pp. 250. \$2.50.

THIS book is largely the outcome of Dr. Mayer's experience as orthopædic surgeon to the Urban Red Cross Hospital and to the Oscar Helene Home for Crippled Children. But although he follows the methods of German orthopædic surgeons to a considerable extent, he pays a tribute to the work of Sir Robert Jones, and in various parts of the book shows evidence of a wide acquaintance with the work of British surgeons. While illustrations of Professor Sauerbruch's operative technique for utilising the muscles of the stump are given, no mention is made of the further developments in this direction made by Signor Putti.

The book deals with the treatment of war injuries before and after admission to the base hospital. Before admission the essential requirement is the proper fixation of the injured part; in the base hospital the problem is to determine the proper time to discontinue fixation and restore motion. In the first part Dr. Mayer discusses the best methods of fixation of limbs with fractures of the bones or injuries to joints, the diagnosis and immediate treatment of injuries to nerves, and the orthopædic treatment of injuries to muscles, tendons, and cutaneous tissues; in the second part he deals with the subsequent treatment in the base hospital. Dr. Mayer emphasises the fact that gunshot injuries to bones do not heal so rapidly as fractures due to indirect violence; after removal of the immobilising splint he advocates the use of an apparatus to protect the injured bone and to restrain the movement of adjacent joints. Macewen's view that the periosteum acts only as a limiting membrane is not upheld by the author; his experiments support the conclusions of Ollier—viz., that the most important of the osteogenetic cells are those lying between the outer fibrous layer of the periosteum and the surface of the bone, the so-called cambium layer of the periosteum. In bone-grafting Dr. Mayer insists on the importance of postponing the operation till all signs of infection have been absent for four months. He refers to his investigations on the anatomy and physiology of tendons and points out the importance of the "paratenon," a name given to the loose areolar tissue containing an unusually large number of elastic fibres, which separates the tendon from the fascia outside the tendon sheath and extends downward into the sheath in the form of a tongue-like fold, the plica. On contraction of the muscle, the plica allows the tendon to glide freely and at the same time maintains the sheath wall intact. The author does not find that electrical tests assist in deciding as to the necessity of an operation on an injured nerve; he places reliance on alterations in sensory symptoms or in the extent of paralysis and the probability of the nerve being directly injured its anatomical course and the direction of the bullet being taken into consideration. Dr. Mayer insists on the value of workshop therapy and lays especial emphasis on the necessity of the Military Orthopædic Hospital including a workshop for the manufacture of artificial limbs and appliances. This shop allows the hospital to make its own splints; it affords opportunities for workshop therapy; it enables every patient to learn how to

mend his own artificial limb or appliance; it teaches some of the men a well-paid trade.

Although the choice of words and phrases is not always happy, the subject-matter is excellent. The book is extraordinarily well illustrated; the text below the figures affords complete explanations.

Medical Ophthalmology. By ARNOLD KNAPP, M.D. *International System of Ophthalmic Practice*, edited by WALTER L. PYLE, A.M., M.D. London: Heinemann. 1918. Pp. 509. 21s.

THE aim of this book is to give the essentials of what is known of the relations of ophthalmology with every other branch of medicine and surgery. The most prominent place is naturally taken by diseases of the nervous system, since in them the presence or absence of optic neuritis may be essential to the diagnosis. Of almost equal importance is an efficient ophthalmoscopic examination in late syphilis, albuminuria, and diabetes, and in many other conditions, especially circulatory. On all these subjects and on others, including ocular tuberculosis, poisons affecting the sight, and the relations of heredity to eye diseases, the volume before us, although from the nature of the subject it contains but comparatively few pronouncements which can be considered final, will be found useful both by the general practitioner and by the ophthalmic surgeon.

The author's endeavour is to give an impartial expression to varying views rather than to press his own conclusions on the reader. It must be confessed that such a book is lacking in the interest which belongs to one in which first-hand observation predominates, such, for instance, as Gowers's "Medical Ophthalmoscopy." On the other hand, it is more comprehensive and necessarily more up to date, though in this latter respect it will doubtless need revision if it is to become a permanently valuable text-book. The section, for instance, on ocular symptoms of head injuries is principally based on pre-war writings in the Graefe-Saemisch text-book, and ignores many important observations which have already been published by English and French surgeons within the last four years. We may suggest, too, that the addition of illustrations and ophthalmoscopic pictures to the text would greatly add to the quick comprehension of the book. The illustrations already there are entirely confined to the preliminary chapter on the anatomy and physiology of the visual paths and ocular nerves. The subject of treatment is entirely outside the scope of the volume.

Medical and Surgical Reports of the Episcopal Hospital. Vol. IV. Philadelphia: W. J. Dorman. Pp. 326.

TEN short articles in this volume refer to ophthalmic subjects. The most valuable of them is a description of a case of implantation cyst of the anterior chamber by Dr. Goldberg, illustrated by two good drawings. Dr. F. Kraus contributes an article on bilateral choked disc following thyroidectomy of some speculative interest, and another on a method for the ligation of the ophthalmic vein for exophthalmos, with the report of a case. The clinical report of a case of mirror writing, by Dr. S. H. Brown, is also of interest as showing what can be effected by a painstaking teacher in counteracting this rare abnormality.

The Ship Captain's Medical Guide. Edited by CHARLES BURLAND, M.D. BRUX., F.R.G.S., Senior Medical Inspector to the Board of Trade. London and Edinburgh: His Majesty's Stationery Office; Dublin: E. Ponsonby, Ltd. Pp. 172. 2s. net.

THE ideal in which no ship would put to sea without having a competent surgeon on board can never be realised, and the need of such a manual as this will always be necessary. The various accidents and diseases that are likely to occur on board ship are explained as completely as possible, having regard to the fact that the practitioner will be a layman; if the instructions are intelligently carried out, much avoidable sickness and suffering among the crews will be obviated. Scales of medicine and lists of the medicinal stores issued by the Board of Trade are given, as well as invalid diets, while stress is laid on the importance of watchfulness in preventing disease. We note with satisfaction that careful attention has been paid to those diseases which, owing to the exigencies of war, may prove more than ordinarily troublesome—infectious diseases, plague, malarial

fevers, and venereal disease. Regarding this last matter attention is called to the importance of instructing the crew in the dangers of infection and the value of prophylaxis. Together with a knowledge of first-aid (which all candidates for master's and mate's certificates must now possess), the book should prove useful to travellers in places where skilled medical advice is unobtainable. The last edition of the book was published in 1912, a new edition having been called for in consequence of a large number of copies having been destroyed with the ships that contained them.

Transactions of the Sixth International Dental Congress.
Published by the Committee of Organisation, 19, Hanover-square, London, W. Pp. 753.

THE Sixth International Dental Congress was held in London in August, 1914, but owing to the outbreak of war the work of the Congress was considerably curtailed. The transactions of the various meetings have been issued recently and form a useful contribution to the science of dentistry. Although the majority of the papers deal with purely technical subjects there are a few communications of interest to those not engaged in the practice of dentistry. The paper on the Teeth of the Australian and Tasmanian Aborigines, by B. Nicholls, should be of great value to anthropologists, and the paper on the Evolution of the Human Dentition, by J. Humphreys, is a useful résumé of our present knowledge of this subject. In the section on oral surgery there are several papers well worthy of careful perusal; of these, the most interesting are those on Cysts of the Dental System, by L. Widman, of Stockholm; Regeneration of the Mandible after Caries and Necrosis, by H. M. Oryer (America); and Dental Sepsis as a Predisposing Cause of Cancer, by F. St. J. Steadman.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

ITALIAN ICHTHYOL—SYN. AMMONIUM SULPHO- ICHTHYOLATE.

(SOCIETÀ INDUSTRIE CHIMICHE, NAPLES. AGENCY: PAUL BEHREND, 4, ADRIA ROAD, DIDSBURY, MANCHESTER.)

THE discovery of ichthyolitic shales in the mountainous regions of Giffoni Vallepiiana, Salerno, has opened up a supply of Italian ichthyol which, according to our examination, is not in any degree inferior to that produced in the Tyrol (Seefeld). The therapeutic importance of ichthyol probably depends upon the presence of "sulphidic" sulphur associated with an organic group. Sulphuretted hydrogen itself has marked bactericidal properties. The sulphur in this Italian ichthyol, according to our analysis, is distributed as follows: As sulphionate, 1.9 per cent.; as sulphate, 2.0 per cent.; and as sulphidic sulphur, 4.5 per cent.; giving a total amount of 8.4 per cent. of the element. It is easily soluble in water, yielding a dark brown, practically clear fluid without deposit. The sulphur compound is possibly present in the colloidal form, which adds to its activity as a therapeutic agent, to quote some cases of its application in gynaecological, urological, and dermatological practice. The ammonia set free by magnesia amounted to 4.60 per cent., and the loss on prolonged heating at 100°C. was 56.60 per cent.; this includes a small proportion of volatile matter, the bulk of this loss being due to moisture. The manufacture of ichthyol consists in the distillation of the shale and the subsequent sulphonation of the resulting oil.

INFLUENZA VACCINE (MIXED).

(BURROUGHS, WELLOOME, AND CO., SNOW HILL BUILDINGS, E.C.)

This mixed vaccine is based on the directions which resulted from the Conference on Preventive Vaccination for Influenza held at the War Office on Oct. 14th, 1918.¹ Each cubic centimetre contains 60 millions *B. influenzae*, 200 millions pneumococci, and 80 millions streptococci, and includes, it is stated, more than 20 strains isolated from cases occurring during the present epidemic. The "first dose" is represented in 0.5 c.cm. and the "second dose" in

1 c.cm., as laid down by the Conference. The vaccine is contained in 1 c.cm. phials and 25 c.cm. rubber-capped bottles.

ETHYL CHLORIDE FILMS.

(HEDLEY AND CO. (LEYTONSTONE), LTD., 120, HARROW-ROAD, LEYTONSTONE, LONDON, E. 11.)

The ready solubility of so many useful medicaments in the easily volatile ethyl chloride has suggested an interesting method of employing these drugs for local application. The following are examples of ethyl chloride solutions which we have examined, but the list is an extensive one: Iodine (3 per cent.) menthol, salicylic acid, resorcin, phenetol et satrol, and iod. form. The liquid sprayed on the skin rapidly evaporates and leaves a perfectly uniform film of the active constituent which, unlike a loose powder, adheres firmly. The useful applications of this method will readily occur, but mention may be made of such examples as the employment of antiseptics, vesicants, or soothing agents to the skin, local analgesics (menthol), parasiticides, and plastic protectives. The merits of this ingenious and effective method may well claim attention.

GENASPRIN.

(GENATOSAN, LTD., 12, CHELSEA STREET, LONDON, W.C. 1.)

The purity of acetyl-salicylic acid is of importance if its dissolution is required to be deferred until the drug reaches the alkaline intestinal juice. We found neither free salicylic nor acetic acid in this preparation. The tablet disintegrates satisfactorily in water, and gives absolutely no violet colouration with ferric chloride. On adding 0.2 per cent. hydrochloric acid, representing the acidity of the gastric juice, there is still no response to the iron test, slight hydrolysis only taking place after several hours. The claim is substantiated that this preparation is a particularly pure specimen of acetyl-salicylic acid.

"COFECTANT" LOZENGES.

(EDWARD COOK AND CO., LTD., BOW, LONDON, E.)

The germicidal efficiency of "cofectant" a non-toxic coal-tar derived phenoloid, was definitely established in our inquiry on disinfectants some years ago. It is well adapted to form the antiseptic basis of a lozenge coupled with some eucalyptus and peppermint. The lozenges are well designed and are free from any harsh effect in the mouth, where, in fact, they are agreeably demulcent. Apart from their value in keeping the mouth clean in a real aseptic sense, and relieving irritable conditions of the throat, they serve also as an antifermentative, and they therefore prove useful in certain dyspeptic conditions.

(1) FEROXAL; AND (2) VERONIDIA.

(MODE-N PHARMACEUTICALS, 48, MORTIMER-STREET, CAVENTISH-SQUARE, LONDON, W. 1.)

(1) We are not aware that protoxalate of iron has been prescribed in this country to any extent, though Mr. W. Martindale mentions it as being included in Spanish and Hungarian pharmacopœias and as having been given in anaemia and as a nerve tonic. Combined with the alkaline phosphate of sodium under the name of "feroxal" it is reported, chiefly in French clinics and recently, to be of peculiar value in the anaemia and chlorosis of pregnancy and in debilitated conditions generally. We found the composition of "feroxal" to be as stated. The dose is small, as otherwise the toxicity of the oxalic group might give rise to apprehension, although the acid is present in many foods, notably cocoa, tea, spinach, and rhubarb. (2) Veronidia provides an agreeable way of administering a well-known hypnotic, under, of course, the direction of the physician. It is a syrupy preparation containing aromatic, glycerine and spirit as solvents, preservatives, and flavouring agents.

BRIGHTON HOSPITAL SUNDAY FUND.—The allocation of the sum collected in the churches and chapels of Brighton, Hove, and Preston, on Hospital Sunday (Oct. 27th) has just been made. The total sum collected was £1220 12s. 1d., and the highest grants made have been as follows:—Royal Sussex County Hospital, £528; Royal Alexandra Hospital for Sick Children, £135; Brighton, Hove, and Preston Dispensary, £132; Queen's Nurses, £102 10s.; Hospital for Women, £98. Two circumstances told against the previous year's total of £1527 15s. 3d. being reached—the wet Sunday, and the fact that the day before was one of many "flag" days.

¹ THE LANCET, Oct. 26th, 1918, p. 562.

THE LANCET.

LONDON: SATURDAY, JANUARY 4, 1919.

A New Year's Wish.

THE New Year opens with so much immediately ahead of the medical profession that no one can say what matters call most urgently for attention, or what particular developments will be the first to receive the public interest without which progress can be but hardly made. We have a new world and a new sort of Parliament to direct our energies for national and for international good, and in this challenging environment medicine takes a stand, ready to alter in the cause of truth, while strong to maintain the proven essentials of science. And this much is certain, the public will expect from medicine an amount of prevision and guidance which has never before been sought from us. That the good health of the people is the people's greatest asset is now universally admitted, from which it follows that legislation with such an objective will be warmly welcomed, and from which it *should* follow that medical advice will be sought and acted upon by Parliament to an increasing degree. Our professional voice in the new Parliament cannot be a loud one—this will be apparent from the result of the polls in which medical men were concerned, and which we publish elsewhere; but if what the medical Members say within the Senate is found to reflect a solid consensus of scientific opinion without benefit to the nation of supreme value should follow. May the New Year bring, out of the many schemes to the same end, a real union of medical men, in which our national services may be properly recognised and fully utilised.

Lessons of a Great Epidemic: the Pathology of Influenza.

THE second wave of a great and—let us be frank about it—unexpected epidemic has passed over our heads and left us breathless, indeed, but seized of a firm resolution to get even with the greatest plague of modern times. On the clinical aspect of influenza fresh light is thrown by the important work done at Aldershot which we print at the front of this issue of THE LANCET. On this, as well as on the epidemiological aspect of influenza, we reserve comment until next week. For while the morbid chain may be broken at any of its links—epidemiological, etiological, pathological, or clinical—it is, at the moment, to pathology that the thoughts of many have turned with the greatest prospect of result. To the October number of the *Medical Supplement* there was contributed an admirable review of the etiology and pathology of influenza. We can recall no more masterly review in our language of this or, indeed, any other "war disease" during the last four years, so that discussing the more recent developments it is fitting

to take it as a basis. As a result of his study of the literature, European and American, the author (Dr. RAJKMANN) concludes: "The cold logic of the post-mortem room in the dispassionate home surroundings does not leave, however, any doubt that *B. Pfeiffer* when present did not play any more important part than the ubiquitous diplo-streptococcus. The real virus, classified *faute de mieux* as 'invisible,' or a 'filter-passer,' so as to cloak our ignorance of its nature, remains to be discovered." How far are these conclusions borne out by the later studies? As indicated by more than one of the articles which appear in this and last week's issues of THE LANCET, the diplo-streptococcus is still with us. But two, at first sight directly contradictory, series of observations deserve note. On the one hand, whereas the earlier literature of this epidemic laid stress upon the infrequency, or at least inconstancy, of the discovery of the influenza bacillus in the sputum, its rare recovery from the lungs in cases of influenzal pneumonia, its still rarer recovery from the blood, and this on the part of trained bacteriologists of the first class, to-day with a striking unanimity those who have succeeded in preparing sterile trypsinised blood media along the lines laid down by MATTHEWS,¹ or who, following LEVINTHAL,² have employed heated blood media, announce that Pfeiffer's bacillus is obtainable in abundance from the sputum of practically every case of the disease. On the other hand, we have the series of observations which from various sources, confirming one another, appear to establish a "filter-passer" as the primary agent and essential cause. This series was begun by SELTER,³ who sprayed his own throat and that of his assistant with a saline filtrate of throat swabbings and throat washings of several patients. Each developed a typical though mild attack of influenza. Next, NICOLLE and LEBAILLY,⁴ in Algeria, making a similar saline filtrate through a Chamberland (porcelain) L. bougie, conveyed the disease to monkeys by intranasal and conjunctival introduction of the filtrate, intravenous injection producing no results. Subcutaneous injection of the filtrate into two volunteer subjects induced the typical disease. At the meeting of the Académie des Sciences a week later, DUJARRIC DE LA RIVIÈRE⁵ reported that the filtered mixed defibrinated blood of four patients inoculated subcutaneously induced in himself a well-marked attack of the disease. More recently GIBSON, BOWMAN, and CONNOR,⁶ working under the Adviser in Pathology of the British Forces in France, Colonel CUMMINS, A.M.S., at an Army laboratory in France, with the aid of the Medical Research Committee, confirmed the observations of NICOLLE and LEBAILLY as regards the effects of intranasal and conjunctival injections upon monkeys, and call special attention to the development of pulmonary hæmorrhages and hæmorrhagic

¹ THE LANCET, 1918, II., 104.

² Ztschr. f. Hygiene, 1918, lxxxvi., 1; and Berl. klin. Wochenschr., 1918, IV., 712.

³ Deutsche med. Wchnschr., 1918, xlv., 932. It deserves note that in 1917 Major G. B. Foster, junior, of the U.S. Army, had brought forward evidence that a "filter-passer" is the active agent in the production and spread of common "colds" (Jl. of Infectious Diseases, 1917, xxi., 461).

⁴ Ctes. Rend. Acad. des Sciences, Oct. 14th, 1918, 617, and Presse Méd., Oct. 17th, 1918.

⁵ Ibid., Oct. 21st, 1918.

⁶ Brit. Med. Jour., 1918, II., 645.

exudates into the alveoli of the inoculated animals. The affected animals afforded no cultures of the influenza bacillus.

How are these apparently opposing sets of facts to be harmonised? To this all pathologists who have studied the lesions of fatal cases are agreed—namely, that, in Dr. RAJKMANN'S words, "The essence of the whole pathological picture consists in the abundance of hæmorrhages seen in the mucous and serous membranes and in the lungs. The whole process seems to be primarily a bacteriæmia localised in particular in the pulmonary blood-vessels. Hæmorrhages in the lungs pave the way for secondary infections." Now characteristically the influenza bacillus is absent from the blood in the early stages of the disease. It cannot, therefore, be the cause of the outstanding vascular lesions. Accepting the influenza bacillus as constantly associated with the disease—at least in this later phase of the epidemic—we are met thus with the alternative, either that we deal with one organism which presents itself in two phases, a minute filterable form which becomes hæmal and a bacillary form mainly developed in the air-passages, or we deal with a symbiosis, and are to regard the filterable form as gaining entrance through the air passages, and by its presence favouring the coincident growth of Pfeiffer's bacillus, and this in such a way that the two viruses are conveyed together from individual to individual. Such symbiotic growth of the filterable virus and the diplo-streptococcus was first suggested by SELTER, and, remembering the so frequently recorded presence of a "diplo-streptococcus" there presents itself a third possibility—namely, that minute forms of this small organism constitute the filter-passers, and that we deal pre-eminently with a symbiosis of a two-phased streptococcus and the influenza bacillus. In favour of this view is the fact that streptococci as a group are hæmal organisms, with a tendency to multiply and form bacterial emboli in capillaries, and that LITTLE, employing the diplo-streptococcus isolated by him from a large proportion of fatal cases⁷ (a form identical with or closely allied to the *Diplococcus epidemicus*, which BERNHARDT⁸ regards as the essential cause of the disease), has been able to set up in rabbits a fatal condition in which early pulmonary hæmorrhagic lesions are the characteristic feature.

It is along these lines, it would seem, that the problem is to be solved. Will the "filter-passers" remain invisible, or, when grown under suitable conditions, will it develop into a visible streptococcal or a bacillary form? If it will not, then the symbiotic theory will have to be accepted, or the closely allied view, which has gained much support from French workers, of composite and successive infection. Here one organism, the filter-passers, preparing the ground for another, the influenza bacillus, which for a time flourishes and has the upper hand, and in its turn prepares the way for, and is replaced by, a member of the streptococcus group, or by the

pneumococcus, just as in the maturation of a dung-heap we find a succession of forms replacing each other until the cellulose of the straw and the proteids of the excreta are broken down stage by stage into their elementary constituents. Of these two views the symbiosis hypothesis, with coincident conveyance from throat to throat of two or more species of micro-organisms, appeals to us, we confess, as meeting more closely the observed facts of the epidemic.

A Fellowship of Medicine.

AT the beginning of last month Sir ARBUTHNOT LANE presided over a meeting held at the house of the Royal Society of Medicine to consider the desirability of forming an association for coöperation in medicine among the English-speaking countries. It was understood that the national limitations thus indicated would not be insisted upon, though for the time being the promotion of mutual understanding between the medical profession in the United States and the British Empire was the main objective of the movement. The meeting at the Royal Society of Medicine grew out of an earlier and informal gathering held at the invitation of Lord EUSTACE PERCY, at which it was urged that the opportunity presented by the coming together of medical men from America and all parts of the British Dominions should be utilised to organise some permanent form of organisation. At that meeting the obvious arguments for the advancement of some plan mutually beneficial to the medical profession of both nations were ably stated by the host and convener, and by others present, and as a result Sir STCLAIR THOMSON and Mr. J. Y. W. MACALISTER were asked to act as honorary secretaries and requested to formulate a scheme. These two well-chosen representatives of science and organisation having consented to do their best, at the meeting at the house of the Royal Society of Medicine a short report was submitted by them on Dec. 4th, and from this report it appears that the Royal Society of Medicine has generously agreed to let the new organisation have office room in the house of the Society, so that 1, Wimpole-street, may now be regarded as the official headquarters of the movement.

The Royal Society of Medicine has now issued a cordial invitation to the medical men of the Dominions and America, as well as to the medical men of all the Allies, to use the buildings of the Society as the home of a Fellowship of Medicine, which henceforth has a local habitation with a tentative name—"The Inter-Allied Fellowship of Medicine." Further support of the movement has been reported on the part of the Director-General of the Army Medical Service, Surgeon-General GOODWIN, who has arranged that in all the commands the medical officers from overseas should be cordially invited to attend clinics, lectures, and demonstrations, and be given every facility for imparting as well as obtaining information. As regards London, the principal hospitals have been invited to extend the teaching of their institutions to overseas medical officers, and a general invitation has been accordingly given to our medical colleagues to come to the hospitals at stated hours and to attend lectures or operations. We wish we could add that the London hospitals

⁷ See Little, Garofalo, and Williams, THE LANCET, 1918, II., 34; and Little, 1918, II., 707.

⁸ Med. Klin., 1918, xiv., 683.

were with one accord ready to welcome American medical men, medical men from the Dominions, and representatives of our science from among all our Allies to a properly arranged course of post-graduate instruction. As yet no such organisation exists, and the pity of this is now terribly apparent. Here, in London, we have unexampled opportunities. Our pathological material is unrivalled. The local centre of the medicine of six millions of people, London is the metropolis of an empire beneath whose sway—no statement to be proud of—every disease in nosological nomenclature occurs daily, and the meeting place of the doctors of civilisation, and of the tropical disorders of the world. No centre offers such clinical opportunities to the post-graduate student, and no city has taken less trouble to display its wealth for the benefit of those, who, by obtaining a share of it, might disseminate what they thus obtained to the incalculable advantage of the world. The Fellowship of Medicine was founded because the congregation, in circumstances of war, of medical men from all parts of the United States and of our Dominions called for some practical outcome of the reunion. The most practical issue conceivable would be that those who joined the Fellowship would find themselves post-graduate students of the Metropolitan Medical Schools, and we trust that this is what may occur. This is said with no ignorance of the severe task of organisation that lies before those who would put any scheme of the sort into being. There is a great deal of spade work to be done before the London hospitals can provide some symmetrical yet flexible post-graduate scheme from which we and our Allies could derive real profit. But before the war Berlin and Vienna could give solid reasons why post-graduate students from other countries should resort to their clinics. Berlin and Vienna will issue no invitations in the immediate future, and if they did the invitations would be declined. The opportunity of New York and London is unparalleled: speaking only for London, why should it not be taken? Dr. HALE WHITE, on another page, asks the same question in pertinent manner.

To return to the doings of the Fellowship, the report, presented by Mr. MACALISTER, was supported by Sir STCLAIR THOMSON, who, in recommending its adoption, urged the desirability of establishing individual coöperation. He said that if volunteers would offer to take personally conducted parties to visit institutions a permanent *entente* would be created. This is true, but a series of disconnected and desultory visits to London hospitals will count for nothing that is permanent in pathology, however deep the memory of the casual hospitality may be. At the end of the meeting at the Royal Society of Medicine a general committee was nominated, Sir ARBUTHNOT LANE being appointed honorary treasurer and Sir STCLAIR THOMSON, Mr. DOUGLAS HARMER, and Mr. J. Y. W. MACALISTER honorary secretaries. To the officers of the new movement we would point out earnestly that one objective of the Fellowship is clear. It is the institution of a real post-graduate medical school in London, but the preparatory labour will not be light. Moreover, it will have to be undertaken with full knowledge of existing designs in the same direction. It will be necessary that the Fellowship should come into *rapport* with Sir WILLIAM OSLER and others, so that previous thought and accomplishment may not be wasted, and overlapping may be avoided.

Annotations.

"Ne quid nimis."

A SURVEY OF CRIPPLES.¹

BEFORE the participation of the United States of America in the war a survey of all the cripples of Cleveland, Ohio, was made (1915-16) under the auspices of the Welfare Federation of Cleveland. The cripples were located by house-to-house canvassing; to make the objects of the survey known, and to ensure a satisfactory reception of the canvassers the public were informed of the movement through the medium of the daily papers. A section of the public were too helpful; many of the poorer families went to great trouble to produce somebody who would pass for a cripple. The canvasser was followed very closely by the investigator who filled up the carefully drawn-up schedules. The whole of the expenses in connexion with the survey amounted to approximately £2400. As the result 4186 cripples were enumerated, a ratio of 6 per 1000 inhabitants. Of this number 2638 were males and 1548 were females, the preponderance of males being caused by accidents, especially occupational accidents. Seven per cent. of the disabilities were due to congenital causes, 43 per cent. to accidents—one quarter of which, at least, occurred during occupation—and 47 per cent. to disease, 3 per cent. being unclassified. As regards age distribution 22 per cent. were children under 15 years of age, 61 per cent. of working age (15-60 years), and 17 per cent. over working age. Each of these groups present different problems.

Of the children of school age, 246 out of the total 771 were not at school, although special classes for cripples were available. The combined needs of these children for education and care can only be met, the writers consider, by a hospital school. The solitary life of the crippled child at home does not afford the opportunity for the healthy competition upon a footing of equality which the cripple must have to gain the self-assurance and the self-reliance required to care for himself and manage his own affairs. The Massachusetts Hospital School is held up as a model. At this institution over 300 temporarily and permanently crippled children are cared for; the authorities pride themselves on the number of children restored to the ordinary public elementary school with their education as advanced as the sound children of their own age. An outstanding feature of the institution is vocational training by the apprenticeship system. In addition to the routine training by vocational instructors who devote the whole of their time to teaching, children who manifest an interest in a particular trade or occupation are attached to the institution as apprentices. One of the most gratifying results of the survey was its disclosure of the large proportion of cripples who were at work in some gainful occupation. No less than 1743 (59 per cent.) were earning a living; more than half of these were supporting a family or relations. A discount, however, should be made for those cripples not seriously handicapped for normal occupation.

Of the cripples of working age, an estimate of working capacity was made by the directors of the survey; they considered that 29 per cent. were

¹ Education and Occupation of Cripples: A survey, reported by Lucy Wright and Amy Hamburger, in Cleveland, Ohio. Publication of the Red Cross Institute for Crippled and Disabled Men, Series II., Number 3.

not seriously handicapped for normal occupation, 45 per cent. were capable of working at selected trades and processes, while 26 per cent. were too disabled to be able to work alongside normal persons. An analysis of the physical disability in relation to employment showed three groups with a large proportion of unemployed; these were combined defects of arm and leg, combined defects of limb and body, and defects of both feet or legs; many of these cripples used crutches or wheel-chairs, which hindered their finding employment. The unemployed included a small group—either invalids or aged—eager for occupation who could carry on home industries and make some contribution to their own support if they could be taught in their homes. An attempt was made to analyse the reasons for unemployment in the case of 859 cripples. Of these, 22 per cent. were in need of placement at selected trades or processes, 15 per cent. in need of special training or special conditions of work, and 5 per cent. in need of home employment. These are minimal estimates; further information would place in one of these three groups some of the 58 per cent. which, for various reasons, could not be classified; this number includes those who were not helpable, and the inevitable accumulation of those whom it was too late to help with any substantial hope of economic success. In addition to those unemployed, a number were found who were only partially employed or fit for better employment.

The directors of the survey recommend the establishment of a central bureau in Cleveland to represent all the forces touching the lives of cripples most closely—medical, educational, and industrial—and to promote the welfare of all cripples by devising means for providing the latest methods of surgical treatment, industrial training, and placement. Such a bureau would assist any effort in the way of research, educational campaigns, or legislation to prevent crippling. The report serves as a timely reminder that peace produces cripples no less than war. During reconstruction it is to be hoped that the efforts that were being made, notably by Belgium, to provide for the cripples of industry, but which were interrupted by the war, will be renewed with greater force, and that the lessons we have learnt from the treatment of the injured in war may be applied in their entirety to those injured in the battle of life.

THE HOUSING PROBLEM.

MEMBERS of the new House of Commons, when they take their seats, will have fresh in their memories numerous and pointed questions asked by their constituents as to their intention to support and press forward legislation for the better housing of the working classes, and the election will have made it clear to them that the working classes themselves are very keenly alive to the importance of this branch of social reform. In the metropolis the problems presented are perhaps more difficult of solution than elsewhere owing to the largeness of the areas covered by insanitary dwellings, but there exists everywhere the difficulty of providing homes for the inhabitants of such dwellings during the period of demolition and reconstruction, and apparently the policy likely to be adopted by some of the London boroughs is one of building outside their own areas for the benefit of their poorer inhabitants. This will, of course, necessitate increased provision of rail and tramway accommodation.

A recent inquest held by Dr. F. J. Waldo in the borough of Southwark illustrated the shortcomings of the existing system under which it is possible for slum areas to drag out their existence as such long after their shortcomings have been officially recognised and condemned. A chimney-sweep, 52 years of age, was proved to have died from natural causes, chronic bronchitis accelerated by self-neglect, in a single room, 9 feet by 6 feet in size, which he inhabited in a house in Tabard-street. Another chimney-sweep who had lived in the house for 53 years had allowed the deceased to occupy his room rent free, being himself the tenant of the county council at 8s. 6d. a week. The house had long ago been condemned, but apparently had been patched up pending its rebuilding, and these persons had been allowed to continue to inhabit it. The coroner, in addressing the jury, referred to the Tabard-street area as one to which he had frequently called attention—in this we can certainly bear him out—as having been for many years a source of danger to the public, and the jury in returning a verdict in accordance with the medical evidence, expressed their surprise at the continued use of houses after their condemnation as unfit to be inhabited. The war has no doubt put a stop during the past four years to building operations, but the conditions obtaining in Tabard-street were recognised and acknowledged by the local authorities responsible many years before August, 1914, and it certainly seems difficult to say what may be the importance of "condemnation" if it leads to no substantial improvement of the conditions which call for it. The houses of Tabard-street, however, do not stand alone in their unfitness to be the homes of working men and women in a great and wealthy city, and the delay in reconstructing them is not unprecedented or without parallel. The difficulty of dealing with the whole matter of re-housing is now complicated by the cessation of building operations due to the war, but the hopeful feature of the situation is to be found in the apparently general recognition of it to which we have referred. There should be no unemployment in the building trade or in those trades which provide building materials for many years to come.

MIGRATION OF A ROUND WORM INTO THE EAR.

THE entrance of a round worm into the ear from the alimentary canal is a recognised phenomenon, but so rare that the details of any case are of considerable interest. In the *Revue de Laryngologie, d'Otologie et de Rhinologie* Dr. H. Coussieu has reported the following case. A girl, aged 4 years, was brought to him for pain in the right ear which began suddenly eight hours previously. In spite of popular topical remedies she never ceased to cry, and the pain seemed to be paroxysmal. Dr. Coussieu suspected otitis media, but was surprised by the results of the local examination. The tympanic membrane was certainly red and bulging, but the latter condition was limited to the posterior half, and there was no pain in the position of the mastoid and no fever. Examination of the nose and pharynx was negative. Instillations of hot carbolic glycerine and hot compresses were prescribed, with instructions to bring the child on the following day if these means did not give relief. Twenty-four hours later the child was brought again. She had suffered much since the previous day. The membrane was redder and more bulging.

Under local anæsthesia paracentesis was performed, and Dr. Coussieu was surprised not to obtain pus. Hoping the pain would subside after the paracentesis, he left the child in charge of a colleague who was summoned on the following day. The pains became worse and worse, and during the night an attack of syncope, crises of nystagmus, and general convulsions occurred. The meatus was blocked by a vermicular body, like that produced by pressure on a tube of pomade. The practitioner seized the body with a forceps and brought away a living male ascaris, 15 cm. long. The child went to sleep and slept for the greater part of the day. The tympanic incision quickly healed, and recovery was complete. No history could be obtained of the passing of worms. Dr. Coussieu thinks that the pain began when the worm entered the Eustachian tube. On the first examination, eight hours later, it had entered the tympanum and produced bulging of the membrane. It finally escaped by the incision.

MOTORING—PRESENT AND FUTURE.

THE release of petrol, which is to take place on Jan. 10th, should ensure to the medical motorist that sufficiency to carry on his arduous duties which has been denied to him for some months past. Many have had to give up their cars altogether, and most of the remainder have been harassed by the tiny quantity doled out to them. Add to the deficiency of the supply its execrable quality, and the medical motorist may well look forward to better times in more directions than one. Not the least pressing consideration at the moment is the problem as to what cars are likely to be on the market in the near future, and how far and how soon they will offer advantages over pre-war designs. Post-war cars will consist, first, of those produced directly the makers are able to supply anything to the public, and of these there is little to say. But cars produced later as the result of experience gained with motor-car and aero engines during the war will embody many new features and possibly startling novelties; but—only in the future. The first cars to be placed upon the market will not differ very much in appearance or design from their predecessors—except, perhaps, in price. War conditions will have taught the manufacturers to improve the springing and strength of the axles. The present low quality of petrol, which tends to engine fouling and difficult starting, suggests that combustion heads will be detachable and machined, so as to permit of more easy cleaning and less likelihood of carbon deposit. Some device, too, will be fitted to assist the vaporisation of the heavier fractions of the imperfect fuels. Ignition on the cheaper cars may be by coil and accumulators charged by a generator, but the satisfactory high-tension magneto will continue on most cars. Lubrication will probably be automatic, and mechanical starters and electric lighting will form part of the standard equipment. Makers may have embodied many new features in prepared designs, but they have mostly been engaged on munition work and cannot have given such designs practical tests. Before doing so they are not likely to make use of them for the public, at the possible risk of damaging the reputation of their products.

Three points are just now exercising the minds of many motoring doctors—viz., whether to continue with their present cars, having them overhauled if needful, or to dispose of them and try to buy a second-hand War Office car, or to order a new car. The condition of the present car should

certainly influence the decision. The pre-war car must by now have revealed its good and bad points, and often the ills we know of are better than those we know not of! Many of the 1913 and 1914 cars are excellent, and, if desired, can be brought up to date. Shock absorbers or spring gaiters will ensure smooth running, even on our present rough roads. An extra air-inlet on the intake pipe will permit the use of benzol, while a compromise for a mechanical starter may be found by priming the engine with a mixture of equal parts of petrol and ether, which will help to do away with the morning starting exercise. As to the second-hand war cars, it is said that the Government have some 100,000 to dispose of. It has been suggested that it would be a good idea if the respective makers repaired them prior to their disposal, or even took them over and sold them on behalf of the authorities after putting them into thorough running order. If this be done it will not be so great a lottery, though even then some blanks may be drawn. Paint and varnish may camouflage a badly worn engine.

A certain number of makers have already a 1919 programme, but few can give actual dates of delivery. Some, though they are willing to put names on the waiting list, cannot yet state the price. For six months after peace is declared war wages will have to be paid, and materials are at present rationed and high in price. The car-buyer must expect to pay this increase in cost of production. In the meanwhile improvements will be experimented with, and ultimately, when materials and wages reach the normal, though it may never be a pre-war level, then with standardisation a fairly cheap and reliable automobile will be obtainable. It is doubtful, however, whether this position will be reached before 1920. After production really starts there should be a tendency with each month for prices to drop.

"ROYAL" ARMY VETERINARY CORPS.

His Majesty's approval of the prefix "Royal" to the title of the Army Veterinary Corps marks a distinct advance in the status of the military side of the veterinary profession; and, inasmuch as by far the greater bulk of the A.V.C. is at present composed of civilian practitioners with temporary commissions, it is an acknowledgment of the present position of British veterinary science in general. All professions have been afforded an opportunity by the war to prove their worth, and the veterinary profession has responded manfully. Quite recently Major-General Sir Frederick Smith made public some of the work which has been done by the British A.V.C., and it is gratifying to learn from other sources that the French and American Veterinary Corps have acquired much from British methods. The organisation of the corps has been perfected under war conditions, and hospitals have been erected and equipped at the various fronts in a manner that has called forth unstinted praise. It is announced that in regard to the animals treated at the various surgical and special hospitals and at the convalescent depôts on the Western front, recent figures show that 72 per cent. have been evacuated to the Remount Department for re-issue to the front. The percentage of discharged animals has been higher than this, but after four years of war the age of the animals has had its effect on the number of patients judged fit for further active service. As in all previous campaigns, contagious diseases have accounted for a large proportion of admissions

to hospital; these, however, have been so successfully dealt with that contagious diseases of all kinds were responsible for less loss at the time of signing of the armistice than at any other period of the war.

ACIDOSIS AND ITS SIGNIFICANCE.

THE seventh report of the "Special Investigation Committee on Surgical Shock and Allied Conditions," which was appointed by the Medical Research Committee in August, 1917, deals with the controversial question of "acidosis." The name itself is a somewhat unfortunate one for the state which it is used to designate—namely, that in which the normal reserve of potential alkali, practically sodium bicarbonate, in the blood has become reduced below about 70 per cent. of its proper value. It suggests that the reaction of the blood has been changed towards the acid side. This is very rarely the case. We have but to remember that, putting the matter somewhat crudely, blood is made alkaline by the sodium bicarbonate, acid by the dissolved carbon dioxide; so that, if the former goes down, it is only necessary to reduce the latter in proportion in order to maintain the hydrogen-ion concentration at its normal value. The removal of carbon dioxide is effected, as is well known, by increased activity of the respiratory centre. Since it is actual increase of hydrogen-ion concentration that is responsible for the physiological effects of acidity, as shown in Section VI. of the report, it is difficult to see how, apart from this, a reduction in the concentration of sodium bicarbonate should have such serious results as are attributed to the state of acidosis. But it has been found that not only in wound-shock, but after anaesthesia and in diabetes, the alkaline reserve is reduced, and certain observers have held the state of wound-shock to be essentially due to this factor. It is obvious that an important question of treatment is involved. If the decrease in bicarbonate is the actual cause of the state, no further treatment should be required than the administration of alkali. It was therefore necessary to subject the question to a thorough experimental and critical examination. The results of this are given in the report before us. The original report must be consulted for the methods used and details of the experiments. We must be content here with a summary of the conclusions arrived at.

The first point tested was whether the reduction of the alkaline reserve in normal animals has any serious consequences. Although this was reduced by the injection of acid to a lower level than that of the most severe cases of diabetic coma reported, the cats and rabbits used showed no abnormal symptoms, except some slight dyspnoea on exertion. This conclusion is the more convincing because some members of the committee had at one time obtained shock-like symptoms by the injection of acid, but they were ultimately completely convinced that their results were not due to acidosis. The next question discussed is, "Does acidosis favour the production of shock by other agencies, such as hæmorrhage, histamine, peptone, adrenalin, vaso-motor paralysis?" No evidence was found that there is any such effect, except perhaps that acid may exaggerate the depressant action of some anaesthetics. If, then, we are led to the conclusion that acidosis does not produce shock, either directly or indirectly, it is necessary to account for the fall of bicarbonate reserve observed in shock. Evidence is given in

the report that this is the result of defective supply of oxygen to the tissues, brought about by the slowed circulation. Details are given of experiments in which a low blood pressure was produced in different ways, with the result of acidosis of varying degrees of severity. The experiments of Wright and Colebrook, published in these pages,¹ confirm this conclusion. The next section is a valuable account of the factors controlling the reaction of the blood, showing the distinction that is to be made between a reduction of bicarbonate reserve and a real increase in acidity; while the final section describes briefly the methods in use for the actual determination of either of these properties. From the practical point of view emphasis is laid on the cardinal importance of maintaining an adequate oxygen supply to the tissues. Since an increase in the acidity of the blood stimulates the respiratory centre to increased ventilation of the lungs, the production of acid in the tissues tends to correct itself in this way, so that the introduction of alkali may even be injurious. But a significant conclusion drawn from experimental evidence is that "oxidation in the tissues is far more easily rendered inadequate by defective circulation through the capillaries than by a reduction either of the oxygen-carrying power of the blood or of oxygen-tension in the inspired air." As much as 75 per cent. of the total blood volume can be removed from the circulation without harm, provided that it is replaced by gum-saline solution. The value of measurements of the bicarbonate reserve is that they indicate deficient circulation and the need for increasing the volume of the blood. A good supply of oxygen by the blood to the tissues is obviously of importance in restricting the spread of infection by anaerobic organisms. The question of gas gangrene is discussed in a special section, and experiments are given which show that the failure of the circulation cannot be attributed to the production of acid.

MR. HENRY SANDFORD.

ON Christmas Eve, at his house, Bladen, Bromley, Mr. Henry Sandford, the solicitor to this journal, died in the 86th year of his age. Nearly ninety years ago Thomas Wakley, the Founder of THE LANCET, in one of the worst of his many legal embroilments, turned to the firm, of which Mr. Henry Sandford was the senior representative at his death, for help and advice. The firm then included one of Wakley's cousins, and from that time the same firm, now under the style of Potter, Sandford, and Kilvington, has advised the proprietors and editor of THE LANCET to our great benefit.

ALOIS EPSTEIN.

Professor A. Epstein, whose recent death in his seventieth year has escaped general notice, was not only director of the principal children's clinic in Bohemia but had at his disposal the whole of the Prague Foundling Institute for teaching purposes. This combination accounts for the fact that his clinical teaching was so fruitful in result at home and so widely accepted over the world. Epstein's life was, in fact, devoted to the physiology and pathology of the new-born child, and the immediate result of his medical direction of the foundling institution was a drop in mortality from almost incredible figures to 5 per cent., where it has since

¹ THE LANCET, 1918, I, 763.

remained. Excellency Czerny, who writes of the great loss to German pediatrics from Epstein's death, fears that his clinic at Prague will be lost as a German teaching institution. That may well be, but the work which he initiated in Bohemia is, nevertheless, likely to outlive him. Epstein was himself a Bohemian, born at Neuhaus, and graduating M.D. of Prague University. Later he became a corresponding

1. Bohn's palatine nodules. 2. Bednař's pterygoid ulcers. 3. Epstein's pseudo-diphtheria.

member of medical academies in many lands. The pseudo-diphtheria of the new-born specially associated with his name he showed to be the end-stage of the palatine nodules described by Heinrich Bohn and the pterygoid ulcers of Alois Bednař, and all of them due to the mechanical cleansing of the mouth practised by the ignorant midwife or mother. The comparative series of three illustrations of this interesting infection is taken from Dr. A. R. von Reuss's "Diseases of the New-born." Stomach lavage in the suckling and sepsis occurring within the first few days of life were other subjects which Epstein made peculiarly his own. In a single year among 702 children at the Prague Foundling Institute he had 61 cases of septic gastric hæmorrhage. He was also an authority on the manifestations of tuberculosis at an early age.

Dr. I. D. Chepmell, who died on Christmas Eve at his house in Worthing at the advanced age of 90, practised for many years in London and in Paris. He ascribed his long maintenance of robust health to the practice of fencing, of which he was a keen exponent. One of his most distinguished and ever grateful patients was Robert Louis Stevenson. While he was in Paris he acted as Paris correspondent to THE LANCET.

A FIRST instalment of the usual New Year Honours contains the names of three medical men upon whom knighthoods have been conferred. These are Dr. William Leslie Mackenzie, medical officer to the Scottish Local Government Board; Dr. George Dancer Thane, professor of anatomy at University College, London, and principal inspector to the Home Office under the Cruelty to Animals Act, and Lieutenant-Colonel John Hewart, Member of the House of Assembly of the Union of South Africa and Assistant Director of Medical Services of the Union. Sir George Anderson Critchett has been promoted to knighthood in the Victorian Order, and the services of Dr. Robert Bruce Low, late assistant medical officer to the Local Government Board, are recognised by a Companionship of the Bath. To these and others whose names are recorded elsewhere in this issue we offer in the name of the medical profession hearty congratulation.

ON THE TEACHING OF MEDICINE.

BY W. HALE WHITE, M.D. LOND. & DUB.,

COLONEL, R.A.M.C. (T.); CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

RECONSTRUCTION is in the air and it is much to be hoped that ere long the teaching of medicine will be reconstructed and improved. No one should take part in rebuilding the means by which those who study medicine are taught unless he has studied "Some Notes on Medical Education in England" by Sir George Newman, K.C.B. Every reader will feel, when he has finished this admirable pamphlet, that medicine demands such wide knowledge, such high training in clear thinking, such experience in the art of observation, such fostering of research, such judgment in separating the true from the false, and is withal of such importance, not only to individual sufferers but to the well-being of the community, that no trouble or expense is too great to get it taught as well as we know how. Most of us who have had experience of teaching medicine will surely agree with nearly all Sir George Newman's suggested improvements, radical as they are, and would like to see them carried into practice forthwith. The following comment is put forward partly in the hope of keeping alive interest in the matter and partly because the writer has for many years devoted much energy to the teaching of clinical medicine.

Post-graduate Teaching.

Towards the end of the "Notes" Sir George Newman tells us of four main things lacking, and the fourth is post-graduate teaching. It is in this that we are most deficient. Up till now the ordinary medical student has been taught, often by no means as well as he should be, teachers have been found, but frequently they have been atrociously paid, research has been carried on, but under difficulties that should never have hampered it, but the post-graduate in this country has been left without guidance and without any but the poorest encouragement except in the Services. We all trust that one result of the war will be a friendship between those speaking the French, Italian, and English languages, which will make some of us wish to go to our friends' countries and some of them to come to us to study medicine. The wealth of clinical material in London is so great that it is to this city they should be attracted, but unless we make things very different from what they were before the war there is little to tempt them here.

The first improvement in medical education should be to put post-graduate teaching in London on a proper footing, not only for the sake of our visitors and our own doctors who want to come back for a few months to bring themselves up to date, but for the sake of our own prestige. But if it is to be efficient it must be separated from the teaching of ordinary students; at least, that is my experience. Two courses are open, either to have a large hospital and medical school, complete in all clinical departments, devoted to post-graduate teaching only, and this is probably the best, or to have post-graduate teaching at ordinary medical schools, but during the months that the clinical teachers are engaged in post-graduate work they must be absolved from teaching the ordinary student either at the bedside or by lectures. He is best taught in most cases by the clinician who is not past 45 or 50; on the other hand, a post-graduate clinical teacher is probably at his best from 45 to 55, for then he has a wealth of experience, and let us hope has not become unprogressive and discursive. It might be a good thing if there were a separate post-graduate teaching institution, to promote a teacher who had been successful in interesting ordinary medical students in any British school to a clinical post in the post-graduate school, for we should thus be able to secure for it teachers who had already proved their capability to teach.

To put post-graduate instruction in London on an entirely new and a thoroughly efficient basis will require much money and much hard work, but most emphatically it ought to be done and on a large scale, for if first-rate teachers are provided a post-graduate school will attract large numbers of students. Should it be decided to have such a school separate from the ordinary medical school, the difficulty will be to find a large hospital, and it must be large, to provide sufficient clinical and post-mortem material. It must contain all the special departments of a modern hospital, including, if possible, buildings for infectious cases, mental cases, and a lying-in charity. Professors in the clinical subjects

must be appointed, and in addition, there must be professors of clinical chemistry, pathology, and bacteriology, each with well-equipped laboratories. All the professors must be so well paid that they will be able to devote their whole time and energy to teaching and research in the school. Teachers in clinical subjects other than the professors might be allowed private consulting practice. Wherever the post-graduate school is situated there should be close to it a large hostel, with a library, common rooms, and sleeping accommodation for the students who come to it.

The Medical School.

In a medical school teaching ordinary medical students there certainly should be properly paid professors of anatomy, physiology, pathology, bacteriology, clinical chemistry, and pharmacology, and if the preliminary subjects of chemistry, biology, and physics are taught at the school professors of these also. All should be experts in their science, capable of teaching, skilled in investigation, and able to help students to investigate and to think for themselves. It may be said that, judging by our experience, it will be difficult to find enough suitable teachers. The answer is that these posts have up till now in most cases been miserably paid. Let each of these professors have proper status and pay and plenty of men will be found. Supply follows demand. Hitherto many who would have enjoyed a life devoted to these subjects have been forced to the clinical side of their profession in order to gain a livelihood. It seems often to have been thought that all that is necessary to make an efficient school is to build laboratories. The man matters far more than the buildings in which he is housed. Sir George Newman would ensure proper payment by State aid, others prefer the addition to students' fees to be by endowment by private benefaction, but, be that as it may, the fundamental fact is that you cannot expect able men to take these posts unless you give them the position and income to which their ability entitles them. If it is objected, with regard to London, that with so many medical schools as there are there, it would be impossible to pay, as they should be paid, the large number of professors required, the answer is that there ought to be in some cases amalgamation between certain of the present schools; it is well known that something has already been done in this direction with regard to the earlier subjects.

Outline of Scheme.

Turning now to the purely clinical subjects, and taking medicine as an example, some such plan as the following would be, it is suggested, the best way to deal with it, and might, with necessary modifications, be applied to other clinical branches. To teach to the best advantage it is necessary to have plenty of material, and for a large medical school there ought to be, say, 220 medical beds. There should be a professor of clinical medicine who should be physician to 80 of these beds, and two other physicians with 50 beds each. There should be four assistant physicians, each seeing out-patients once a week, two corresponding to the professor, each with 10 beds, so that these assistant physicians should have beds into which they could send, from out-patients, patients whom they wished specially to watch. Of the other two assistant physicians one should correspond with each of the other physicians, and should in addition have 10 beds of his own, for the purpose just mentioned. When the professor is away on a holiday or from illness, his work in the wards should be shared by his two assistant physicians, and when either of the other two physicians is away his corresponding assistant physician should take charge of his beds.

In addition to his ward work, the professor should see out-patients one day a week, so that on five days a week medical out-patients will be seen; he and the four assistant physicians should do out-patient teaching on the days on which they see out-patients. Students will be appointed as out-patient clerks, who will make notes of the cases, and generally assist, and learn at out-patients from the professor or the assistant physician, as the case may be. The two physicians other than the professor should each do bedside teaching three days a week, and the professor should do bedside teaching five days a week. Every ordinary student will work in the medical wards as medical ward clerk for six months, for three of these with the professor and for three with one of the other physicians, half of the students being with each of these physicians; but as every student will work in the wards under the professor, he, having double the number assigned to each

of the physicians, will divide his clerks into two sets. Some of the abler students will have longer than six months in the medical wards, for they will hold the post of clinical assistant, and if qualified that of house physician. Both physicians and the professor will give clinical lectures, one being delivered each week.

The professor will devote his whole time to the duties of his office, he must have what laboratory accommodation he needs, he should be of such a temperament that he can teach clinical medicine and undertake research, and he must do everything he can to encourage and help all who wish to do research under him. It is to be hoped that the assistant physicians will pursue investigations with his sympathy.

Consideration of Some Details.

In details this scheme is a little different from Sir George Newman's. In the first place, the professor is not to engage in private practice. This, I feel, is the right line to adopt. If a man has an aptitude for private practice it is almost impossible for him to say he will only do a little. Quite apart from the fact that if it becomes part of his source of income he can hardly be blamed if he pursues it honourably, there are many cases, and often the most trying, which if he is asked to see he must see; he cannot refuse to go. The professor ought to be so well paid that he can always say he does not engage in private practice. He will then be freed from all its thousand and one worries, and he will have time to think out the problems of medicine that need investigation; he will not be liable to be called off from his laboratory work, and he will have leisure to direct research amongst those working under him.

In the second place, there are other physicians and assistant physicians than the professor. The advantages of this are many. It is desirable that the student should learn medicine from more than one teacher, for it is an art as well as a science, and it will be of distinct benefit to the learner to hear different opinions, to see different methods of treatment and diagnosis, and to observe different lines of thought. Every student on the plan suggested will get part of his training from the professor, a physician, and an assistant physician; this must widen his horizon and help to give him that breadth of outlook which is such a desirable part of real education. Further, no single professor could possibly treat and look after the numerous medical in-patients that a large school ought to possess. The student cannot have too much actual contact with patients, and each should have enough cases assigned to him for note-taking to keep him busy in the wards. He will pay special attention to his own cases, and will at the same time observe and learn under the direction of his teacher from the cases of his fellow-clerks. Also no single teacher can properly teach more than about ten clinical clerks at the same time, for he ought to get to know the minds of each of his clerks so as to help each individual one over his particular difficulties. Other students may come round with the professor and physicians, the more the better, for a large audience brings out the best in a teacher, but his particular attention must be his own clerks.

Lastly, it is much better for the professor himself to have others in the same school teaching medicine; both he and the others mutually stimulate each other. If there is more than one teacher of medicine, each is prompted to try his hardest, so that his teaching may be as valuable as, if not more valuable than, that of his colleagues.

Conditions of Appointment of Staff.

The assistant physicians should be well paid for their teaching, but they should be allowed private practice. In medicine this does not come in great amount to the young, so that the assistant physicians being properly paid would be able to throw nearly all their energy into teaching and investigation. The two physicians, other than the professors, should receive good payment for their bedside teaching and clinical lectures, but this need not be on the scale of the professor's pay, for they should be allowed private practice, and in order that they should be saved from the temptation in later years of neglecting their teaching for private practice they should retire from the hospital at an age certainly not later than 55, the precise age depending on how their private work interfered with that in the hospital and upon the quality of their teaching. The professor should retire at the age of 60. If something of the plan here sketched for medicine were applied to surgery perhaps other ages for retirement would be more suitable.

An advantage of this early retirement would be that the promotion of the assistant physicians would be quicker than it is now. Of the four assistant physicians, two might look forward, if they had proved their value to the school, to a full physician's post, one to a professor's post at his own or some other school, and perhaps one out of the four would ultimately teach at a post-graduate school or practise some special branch of medicine, and, bearing in mind such transference, possible losses from early death or ill-health, and the failure of some to be good teachers, four is often not more than enough to replace three. When an assistant physician is appointed the appointment should at first be for three years only, so that if it were discovered that he had not the art of teaching he need not be reappointed unless it were desirable for other reasons—such as brilliant research—that he should. Those on such a hospital staff who are allowed private practice should confine themselves to purely consulting practice. My object is only to give a general outline of the teaching of clinical medicine, as no mention has been made of how far assistants or demonstrators shall be employed for rudimentary teaching; the practice would vary in different schools.

Special Departments.

In a properly equipped medical school the special departments of medicine should present little difficulty. There should be a physician for children's diseases, who would see out-patients and have charge of a good-sized children's ward, and a physician for mental diseases, also with charge of out-patients and suitable wards for the treatment of early cases. The physician for skin diseases should also see out-patients and have some beds. Many of the commoner nervous diseases, such as cerebral hæmorrhage and chorea and tabes, are best taken into ordinary medical wards, so that the students can learn from them in the course of their ordinary medical work, for such cases will come before them very frequently in general practice, but probably it would be well to have a separate out-patient department for nervous diseases. It would be a great advantage to a medical school to have a fever hospital near to it. The students attending their course of fevers would not waste time going long distances, and those in charge of the general hospital and those in charge of the fever hospital would be able to meet frequently to interchange ideas, and the advice of the professors of medicine, pathology, and clinical chemistry, and the use of the corresponding laboratories would be of help to the physicians in charge of the fever hospitals for any investigations they might want to undertake. I am aware that in this sketch more beds have been assigned to medicine than is possible in some hospitals, but I have put forward the numbers here mentioned as the ideal number when the students are numerous.

Pharmacology and Therapeutics.

The complete medical school must have a properly paid professor of pharmacology with a well-equipped laboratory. The great want is a closer connexion between the professor and clinical work. It would not be wise to give the pharmacologist charge of beds, for he has usually done little clinical work, and before the drugs can be given to a patient the physician in charge must find out what is the matter with him; this is the duty of a clinician, who can usually do it better than a pharmacologist, whose training lies in devising experiments to discover the mode of action of drugs. But there should be close friendly coöperation between the clinician and the pharmacologist, who should be encouraged to go to his clinical colleagues and say, "I want to observe the effects of such and such drugs on such and such diseases; let me know when you have suitable cases, and I will come and make the observations I desire." The clinician would, by seeing the results of the observations, be adding to his own knowledge. Often, too, he would be able to suggest to the pharmacologist fruitful lines of research; it would be a great gain to the progress of medicine if researches at the bedside were made hand-in-hand between the pharmacologist and clinician and published under their joint names.

Sir George Newman has been unfortunate in the impression he has formed about the teaching of therapeutics. He says, "The case is diagnosed and its treatment prescribed, but such treatment is but rarely closely observed or assessed by the student," and again, "Is he a doer of the word, or only a hearer?" Every good clinical teacher, after he has explained to the students how the diagnosis is reached, goes on to talk

over with them the details of the treatment, not only by drugs but by many other methods; he discusses what kind of life the patient should lead, what he should eat and drink, where he should live, and what occupation he should follow; what therapeutic means other than drugs should be employed, such as massage, remedial exercises, electricity, X rays, and so forth; and while the patient is under observation in the hospital he from time to time points out the success or the failure of the therapeutic means that have been adopted. Every single patient that comes into the hospital ought to be the subject of a therapeutic discourse.

A first-rate medical school will have attached to it the necessary therapeutic departments—e.g., massage, remedial exercises, electrical and others, in which the student can see the carrying out of all these special treatments, but it will be a bad thing to have a special teacher of therapeutics—bad for the professor of medicine and the other physicians attached to the hospital, for they will cease to be first-rate physicians if they do not fully know how to treat their patients, and if they do know, why should they not impart their knowledge direct to the students, instead of its filtering through a professor of therapeutics? Should this subject be taken away from clinicians it will have an evil effect upon the students, for they will be encouraged to believe that the treatment of the patient is a thing apart. There has been too much of that in the past. The duty of the physician is to find out what is the matter with the patient, and to treat when possible the condition found. He should frequent the departments where special treatments are carried out, and he must keep himself abreast of all new therapeutic suggestions. He should have an open mind and be able to assess each mode of treatment at its right value. Sir George Newman quotes with approval a lecture course and the accompanying therapeutic clinic thus: "(3) to discuss the pathology of the case and the precise purpose of treatment; (4) to review the relative value of the means of accomplishing the object." This is exactly what the clinical instructor should do as part of his bedside and lecture teaching. If he does not do it he ought, and I hope that it is rare for the student to be "actually unaware of the medicinal treatment to which the patient is subject." If his clinical teacher has not made him aware of it great blame attaches to the teacher, and the cure lies not in appointing a professor of therapeutics, but in getting a better man to do the clinical teaching. However, there is little difference of opinion between Sir George Newman and myself, for although his report covers the whole of medical education, this is the only principal point in which I differ from him.

Pathology and Bacteriology.

Just as the clinical teacher will discuss with his hearers the diagnosis, prognosis, and treatment, so he should indicate to them the pathology of the disease from which the patient is suffering, for this will be necessary to explain the symptoms scientifically. Although the key to many symptoms is to be found in the pathological laboratory rather than the dead-house, yet there are few diseases without some morbid anatomy, and the bedside teacher will, out of hearing of the patient, indicate to his class what might be expected to be found on post-mortem examination, and if the patient dies he should take the students to the post-mortem room and point out how far the conditions found there can be correlated with those observed during life. The most essential thing in teaching medicine is to train the students to visualise what is wrong inside the patient. I frequently take my students away from the bedside to say to them, "Supposing we this very afternoon killed this patient, tell me what you would see on post-mortem examination, for unless you can do that you have not really conceived what is the matter with him."

The professor of pathology will not be the least busy of the professors; pathological research is so fascinating that he will have plenty of enthusiasts working under him whose work he will direct. In addition, he will have his own original work and lectures, so that while, of course, he will have complete control of the dead-house, and, if he likes, make some post-mortem examinations, a great many should be made by the assistant physicians, for, other things being equal, the man who has made most post-mortem examinations is the best physician and the best teacher of medicine. The greatest corrective to any slovenly habits of diagnosis is the knowledge that if the patient dies it may be open to all to see if the diagnosis is correct; therefore students must be taken into the post-mortem room as much as possible, and particularly

when a post-mortem examination is made on any of the cases they have seen during life. The advantage of this in training them to proper diagnoses cannot be overestimated.

The precise relationship of the professor of bacteriology to the professor of pathology will, no doubt, vary in different schools, but ample provision must be made for bacteriology, and the head of the department should be well enough paid to render private practice unnecessary. Indeed, in a large school he should not have time for it as there will be laboratories to be controlled, numerous investigations from in- and out-patients, classes for students, his own research, and many doing research under him who will need advice.

Modern advancements have made a clinical chemistry department absolutely necessary. Good laboratories are essential, and the professor should be on the same footing as those already mentioned. Experience has shown that a large hospital and school will keep him fully employed in routine work from the wards, in teaching, in his own researches, and in those of others.

Examinations.

Before we can get the medical students properly taught the prevailing system of examinations must be altered. There is no doubt that, as at present conducted, they impair teaching, especially the best, and frequently fail to separate the goats from the sheep. I have conducted many examinations, and am fully aware of their shortcomings. It is difficult to frame questions that cannot be as well answered by a student with a retentive memory for what he has read or been taught by a coach, as by one who has gained his knowledge by bedside observation. It is even more difficult to devise a clinical examination that shall fairly test the candidate who, when left quietly to himself, is quite good at his clinical work, yet "goes to pieces" when he feels that everything depends upon his hearing particular murmurs in a limited time. A teacher's opinion as to the fitness of a particular candidate to pass ought to be at least as good as that of the examiner who only knows his man for as many minutes as the teacher knows him for months. Somehow or other, a plan must be devised in which the bedside and laboratory work done by the candidate during his training counts in the examination. This will stimulate the teacher and stimulate the student.

"University Education."

There is no need here to try to explain what is meant by the phrase "university education," for it is fully and admirably expounded by Sir George Newman in Section 3 of his "Notes" and is there illustrated by noble quotations, of which perhaps the finest is that from John Henry Newman's Lectures. But this is certain, that in medicine of all professions the teaching should endeavour to reach the high ideals denoted by the phrase "university education," for he who practises medicine has to deal with a science as well as an art, his mind must be accustomed to the hard facts of the dissecting room and the laboratory, to the process of reasoning required to reach a diagnosis, to the skill necessary to conduct correct treatment, and to the judgment of the proper way of dealing with human beings. His education must not only have taught him facts but must have trained his mind how to think, how to appreciate the relative value of facts, and how always to be receptive of new discoveries and new aspects of old questions. Indeed, it is doubtful whether any profession requires that width of training implied by "university education" more than that of medicine.

The teachers themselves should remember, too, that all through their lives they must educate themselves. It has been too much the habit of some to remain in their wards, others in their laboratories. They should frequently meet; half an hour's conversation between a physician and a physiologist or chemist does immense good to both. In a medical school aspiring to reach a university standard there should be a common room in which all the teachers can meet and exchange views, and each should know the others well. Frequent meetings will have this further great advantage, it will encourage "team-work." In order to solve almost any medical problem it must be regarded from several standpoints. It is to be hoped, therefore, that in the future we shall see much more "team-work" than we have in the past. Speaking generally, "team-work" papers are more complete than those of individuals and contain fewer mistakes, for before publication each author has been able to be a friendly critic to the others.

THE STANDARD ILLUMINATION OF SNELLEN'S TYPES.¹

THE Council of British Ophthalmologists have been well inspired in investigating the circumstances under which Snellen's types are used in testing the vision of candidates for the public services. It has long been realised that in the absence of any standard method of illumination great injustice might be done to candidates. The conditions, for example, on a November day on a ground floor are hardly comparable to those of a well-lighted upper room in summer. The Council of British Ophthalmologists, which consists of the Presidents, past and present, of the Ophthalmological Society of the United Kingdom and of the Section of Ophthalmology of the Royal Society of Medicine as permanent members, is reinforced by elected members both from the society and from the section, and for the purpose of carrying out the investigation the following were appointed as a committee:—Sir George Berry (chairman), Sir Richard Glazebrook, O.B., F.R.S. (Director of the National Physical Laboratory), Mr. O. C. Paterson, O.B.E. (National Physical Laboratory), Mr. Leon Gaster (secretary of the Society of Illuminating Engineers), Mr. J. Herbert Fisher, Colonel J. Herbert Parsons, Mr. A. B. Oridland, and Mr. W. H. MacMullen, O.B.E. (secretary).

The report runs as follows:—

The effect upon visual acuity of variations in the illumination of test objects has been the subject of a series of careful investigations since the time of Tobias Mayer (1744). Two chief facts emerge from these researches: (1) That there is a rapid rise in acuity as the illumination is increased from zero up to about 2 foot-candles; (2) that above 2 or 3 foot-candles there is scarcely any appreciable rise in acuity. The results obtained by different observers are not entirely concordant, the discrepancies being attributable to variations in the test object, contrast, size of pupil, &c. So far as the testing of visual acuity for clinical purposes is concerned, it appears to be sufficiently accurate to regard the results obtained with an illumination of 3 foot-candles or more as valid and comparable under the ordinary conditions of clinical testing.

There is, however, no doubt that this minimum is by no means always ensured under the actual conditions in which the testing of candidates for military or other public services occurs. Apart from the fact, which should be borne in mind, that the test types often do not conform to Snellen's criteria, they are frequently dirty, the diminishing contrast, are tarnished, thus giving rise to disturbing direct reflection of light and are viewed under very great variations of daylight in rooms which are often ill-suited for the purpose.

It is possible to lay down precise and simple rules for the efficient illumination of test types, and we see no reason why these rules should not be generally adopted. For the public services it is, in our opinion, unfair to the candidates and detrimental to the services themselves that examinations should take place under unsatisfactory, and often hurriedly improvised, conditions. The testing of visual capacity is now an essential part of the physical examination of candidates for a large number of the public services, such as the Navy, the Army, the Mercantile Marine, the Indian Civil Service, and so on. We are of opinion that these tests should be conducted under approved conditions, and that this object would be best attained if the examinations were held at properly equipped centres.

We fully recognise that variations of visual acuity arise from many causes other than the actual illumination of the test types, such as the condition of retinal adaptation, contrast between the test object and its background, the size of the pupil, lateral illumination, and so on. We think, however, that these effects can be minimised sufficiently for practical clinical purposes if the testing takes place in a moderately well-illuminated room, with the test types efficiently lighted, and with the careful elimination of any glaring lights, or bright objects from the candidate's field of vision.

We consider that the requirements are sufficiently well satisfied by the following means: Two ordinary 20 watt tungsten lamps (see diagram, L1, L2) with straight filaments are fixed vertically 15 inches in front of the plane of the test card (A, B), one on each side, at a horizontal distance of 12 inches from the vertical plane normal to and bisecting the card. One lamp is placed higher than the other, one being opposite the junction of the upper and middle thirds of the card, the other opposite the junction of the middle and lower thirds. Opaque non-reflecting screens (S, S') are fitted, so as to prevent direct light from the lamps reaching the candidate's eyes.

This method ensures:

(1) Sufficient illumination. With new lamps the illumination on the test types will be of the order of 10 foot-candles. The ordinary variations of current, deterioration of lamps, and the darkening of the test card with age will not reduce the brightness of the test card so illuminated to a value less than that of a perfectly white surface receiving an illumination of 3 foot-candles.

(2) Sufficient uniformity of illumination. Whilst we are aware that the same result can be achieved by the employment of properly designed and carefully placed reflectors we have had to recognise in making these proposals that the testing of visual acuity must often be carried out in circumstances which do not admit of the use of

¹ Report on Standard Illumination of Snellen's Types used in Testing the Vision of Candidates for Public Services. Published for the Council of British Ophthalmologists by G. Pulman and Sons, Ltd., 24, Tavener-street, London, W. 1. Price 6d.

* One foot-candle is the illumination received from a source of one candle-power falling perpendicularly on a surface at a distance of 1 foot from the source.

special lighting arrangements, requiring technical skill in their installation or upkeep. We have, therefore, endeavoured to prescribe a method of ensuring the necessary illumination which is simple to erect, is not liable to become deranged by subsequent treatment, and which enables ordinary lamps on the market to be employed.

Where electric light is not available a similar arrangement can be installed, using other illuminants.

Daylight illumination.—There is no theoretical objection to the use of diffuse daylight so long as the illumination on the test types is adequate—i.e., does not fall below 3 foot candles. In cases of doubt it would be necessary to apply tests requiring the skilled use of some form of photometer. We are, therefore, of opinion that in order to secure uniformity and comparable results artificial illumination should in general be used, and invariably in testing for the public services.

Diagram to illustrate the arrangement recommended to illuminate the test-card.

We therefore make the following recommendations.

I. **The test types.**—The test types shall be of the dimensions laid down by Snellen and printed on a matt white surface.

II. **Illumination.**—(a) The minimum illumination on the test-card shall be such that its brightness shall be equivalent to that of a new card illuminated to at least 3 foot candles. (b) The illumination of the test types shall be as uniform as possible. (c) Artificial illumination shall be used in preference to daylight. (d) The testing-room shall be moderately illuminated, and care shall be taken that there are no glaring lights or bright objects in the candidate's field of vision. (e) Extreme contrast between the illuminated test-card and the background shall be avoided.

III. **Method of lighting.**—(a) The method of lighting described in this report shall be in general adopted. (b) This method shall be made compulsory for sight testing in all public services.

As an appendix there is a note on the illumination of test types by gas or oil lamps.

Gas lighting.—Two "medium" inverted incandescent burners, consuming 2½–2½ cub. ft. of gas per hour, are fixed 2½ ft. in front of the test card, one on each side, at a horizontal distance of 12 inches from the vertical plane, normal to and bisecting the card. One burner should be higher than the other, one being opposite the junction of the upper and middle thirds of the card, the other opposite the junction of the middle and lower thirds. Burners should be equipped with clear glass globes, and care should be taken to ensure, by regular maintenance, that mantles and burners are kept in good order and in clean condition. Opaque non-reflecting screens are fitted so as to prevent direct light from the burners reaching the candidate's eyes.

Oil lighting.—Two standard "Duplex" oil lamps, each having a double straight wick, 1 inch in width, and a chimney 10½ inches in length, are fixed 2 ft. in front of the test card, one on each side, at a horizontal distance of 12 inches from the vertical plane, normal to and bisecting the card. One lamp should be higher than the other; one being opposite the junction of the upper and middle thirds of the card, the other opposite the junction of the middle and lower thirds. The wick should be turned up as high as is possible without smoking, and the face of the wick should be turned towards the card. The distance from top of wick to level of oil in reservoir should not exceed 5 inches. The lamp should be lighted 20 minutes before the test, so as to ensure steady conditions of burning. Opaque, non-reflecting screens are fitted, so as to prevent direct light from the lamps reaching the candidate's eyes.

The Council of British Ophthalmologists was founded in May, 1918, at a general meeting of all ophthalmic surgeons of the United Kingdom held at the Royal Society of Medicine. It was empowered to act in all matters of ophthalmological interest arising in connexion with public affairs and to be ready to provide when called upon a body of expert opinion to advise on any ophthalmic subject. The council, whose constitution has been given above, was founded on a basis which should ensure its authoritative character. The first report of the council, given above, will be seen to deal with an important subject—types used in testing the vision of candidates for public services. The regulations at present in existence with regard to the standard illumination of test types say that these tests shall take place in "ordinary daylight" (Army Regulations) or "in a good light, but not in direct sunlight" (Board of Trade Regulations for Mercantile Marine). In practice (as has been said above) this may mean anything, and a more definite standard was obviously required in the interests of the public and the candidates alike. The council was fortunate in securing valuable scientific co-operation in the preparation of its report. The suggestions are straightforward, and the object aimed at should be secured at very small cost.

MEDICAL CANDIDATURE FOR PARLIAMENT.

SUCCESSFUL AND UNSUCCESSFUL.

MEMBERS of the medical profession were candidates for Parliamentary suffrage in at least 32 constituencies in the British Isles during the recent General Election. From the results made public last Saturday, Dec. 28th, it will be seen that in more than a third of these contested elections they were successful. We append a complete list, so far as we know it, of the constituencies in which a medical man took part in the contest, giving in each case his position in the poll (in black figures), the total number of voters (in square brackets), and the number of votes secured by the medical man and his competitors, along with the political labels by which they were known. An asterisk is placed against the name of any medical man who sat in the last Parliament. Whether successful or not, the experience gained should be of use to others.

along with three others who have already established their position there:—

DR. CHRISTOPHER ADDISON, SIR WATSON CHEYNE,
SIR AUCKLAND GEDDES.

On behalf of several of these successful candidates we have been asked to express gratitude to their professional colleagues for help freely rendered.

MEDICINE AND THE LAW.

Illicit Traffic in Drugs.

THE inquest, which has not yet been concluded, upon the body of a young actress named Stewart and known upon the stage as "Billie Carleton" has already produced as one of its results the prosecution and conviction of two persons—Len Ping You, a Chinaman, and his wife Ada, a British subject by birth. They were mentioned in the early stages of the inquest upon Miss Stewart, with allegations as to the wife having assisted the deceased and others in the smoking of opium, and owing to the facts thus disclosed they were recently charged simultaneously at two different police-courts. The Chinese husband was arrested at Limehouse Causeway, where he lived, and brought before Mr. Rooth at the Thames police-court, who sentenced him to pay a fine of £10 for having opium in his possession without authority, and also for having an opium pipe and other utensils connected with this use of the drug, the offence, to which he pleaded guilty, being one against a regulation made under the Defence of the Realm Act. The wife, Ada, was brought before Mr. Mead, at Marlborough-street, and charged with supplying opium prepared for smoking to Miss Stewart, and also with being in possession of prepared opium at 16, Dover-street, where rooms were occupied by a man named De Veuille and his wife. To the latter charge she pleaded guilty, having denied supplying the opium at the time of her arrest and afterwards. The facts narrated by the solicitor for the prosecution as to the use which the prisoner made of a drug, which possibly, if she told the truth, she found already provided on the premises, were of a character to earn for her a sentence of five months' imprisonment with hard labour. Acting as a "priestess of unholy rites," to adopt the phrase of Mr. Mead, the magistrate, she filled and lit the opium pipe which passed from mouth to mouth in an opium-smoking debauch lasting from 10 o'clock one Saturday evening until 3 o'clock on the following afternoon. The party to whom she thus ministered consisted of five or six young men and women, for whom cushions were spread upon the floor, and who before taking part removed their clothes and put on pyjamas and night-dresses respectively. Miss Stewart, who arrived late after a performance at the theatre where she was engaged, was one of these. The observations made by the magistrate upon what he characterised as a disgraceful orgy, and the sentence which he passed upon the woman who took so leading a part in promoting it, can hardly be criticised as too severe. It is to be noted also that he described

indulgence in opium as a prevalent form of vice, and expressed the hope that the imprisonment which he was ordering the prisoner to undergo would act as a warning to others. The frequency of prosecutions for this kind of offence recently to be observed in police reports may to some extent be due to there being more space than formerly for the publication of such items of news, but whether this is so or not it is evident that the use of opium, cocaine, and other drugs in late years has attained substantial proportions, in spite of the efforts made by the authorities under the Defence of the Realm Act to hinder the illicit traffic. It is to be hoped that whenever that statute may become obsolete permanent provision will be made to protect the willing victims of drug-taking from themselves and from the temptations placed in their way by others. The use of cocaine by soldiers, to prevent which a special effort has been made through the regulations under "D.O.R.A.," is said to be due to an alleged effect of the drug in producing a reckless indifference to environment and disregard of danger. The circumstances of war service have ceased, but the desire for temporary relief from anxiety or discomfort will contribute even now to render men and women anxious to obtain drugs, the surreptitious importation and sale of which it is very difficult to prevent. Among typical recent cases we note one of a Chinese cook caught with two pounds of opium, which he might have sold for anything up to £60, under his shirt. He was fined £22 at Tower Bridge police-court, and another Chinaman was charged on the same day at the Thames police-court for keeping an opium den at Limehouse and fined £10. Cocaine is even more easily carried and concealed than opium, and perhaps on this account and for the reasons above suggested commends itself to many drug-takers, who, however, do not appear at once to adopt a particular form of intoxication, but prefer to experiment for a time with whatever opportunity may throw in their way. This, at least, is the impression conveyed by the reports of the inquest upon Miss Stewart and the other cases which have arisen out of it. In connexion with the use of cocaine we call attention to the conviction at Liverpool of a woman for stealing a bottle of cocaine from the consulting room of a dentist who was treating her. This should be a warning to medical men who dispense their own medicines of the great importance of keeping all dangerous drugs beyond the reach of their patients.

An Ingenious Impersonator.

At the Bromley (Kent) police-court recently a man named James Allan was ordered to pay a fine of £20 and £10 costs after being proved to have used medical titles and practised as a medical man in somewhat unusual circumstances. The name of a Mr. James Allan, who had duly qualified at Edinburgh University, appeared with the usual particulars of his qualifications in the Medical Register from 1892 to 1898, when he died. In 1901 there were published in the "Medical Directory" the same name and qualifications, "James Allan, M.B., C.M. Edinburgh," and they continued so to appear until the conferring of the order of Officer of the British Empire upon a gentleman so described attracted the attention of the Registrar of the General Medical Council, who was unable to find a corresponding entry in the Medical Register. At or about the same time one of the usual forms issued for the purpose of corrections or additions by the publishers of the Medical Directory was sent to Mr. James Allan at his address at Chislehurst, and was returned by him with the addition of the letters O.B.E. After inquiries had been made by the Registrar of the General Medical Council, the matter was laid before the Director of Public Prosecutions with the above result. The defendant was stated by counsel to be the son of a farmer in Ireland, who had been at one time a shop assistant and had afterwards studied medicine. He had not qualified as a medical practitioner, but had acted as an unqualified assistant to medical men, and since 1902 had practised at Chislehurst as James Allan, M.B., C.M. Edin., and in that capacity had signed death certificates. A charge made in respect of these was not proceeded with by the prosecution. A detail which was mentioned in the case should be noted by the personal representatives of medical men. After the death of the real James Allan, referred to above, his sister was asked by someone who wrote from Glasgow and was stated to be an acquaintance of the defendant, whether she would sell her brother's medical diplomas, the

writer stating that he had a hobby for collecting such documents. The object of the offer, in so far as it proceeded from the defendant, is obvious, and as the diplomas of deceased medical men cannot, except perhaps in the case of a few distinguished personages, be of any interest except to their children or other relatives, willingness to pay for them on the part of a stranger should at once excite suspicion on the part of the possessor. James Allan, of Chislehurst, cannot complain that the punishment inflicted upon him was in excess of his deserts, in spite of the fact that witnesses, including the rector of Chislehurst, expressed themselves satisfied with the skill with which he treated his patients. This was a bad case of impersonation, and if the prosecution had laid stress upon the points involved the proceedings could hardly have stopped where they did. We feel sure that those responsible for so carefully edited a work as the Medical Directory must keenly regret the inaccuracy which in some way was admitted to its pages.

Frost v. King Edward VII. National Memorial Association for the Prevention, Treatment, and Abolition of Tuberculosis.

In this action, in which Mr. Justice Eve granted in last May an injunction to restrain the defendants from using Cardigan House, at Newport, Monmouthshire, as a hospital for surgical tuberculosis, a settlement has been arrived at. This was announced by counsel when the case was called in the Court of Appeal, the terms being stated to be that the house should continue to be used as before until the expiration of six months after peace, and then should become a residence for one of the physicians of the association and a central dispensary for their work in Newport and Monmouthshire. Conditions were added such as should make the settlement a binding one and prevent any further litigation in the future, and it was provided that the defendants should pay the taxed costs of the plaintiff.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

A MEETING of the Committee was held at THE LANCET Offices on Dec. 23rd, 1918, when Dr. SQUIRE SPRIGGE reported that he had received through Lord Hardinge the necessary forms to secure a passport for a representative of the Fund to go to Belgium, the only preliminary formality being the favourable recommendation of the Belgian Control Office. Dr. Sprigge also reported a visit from Dr. Théo Huyberechts, who had come as a member of the Belgian Doctors' and Pharmacists' Committee sitting in Brussels, to express the gratitude of that Committee to the Fund, testifying that the help of the Fund had been "beyond words valuable."

Sir RICKMAN GODLEE called the attention of the Committee to the fact that there remained at their disposal many instruments still housed at the Apothecaries' Hall. One selection, he said, had been packed and sent, under the superintendence of Mr. Samuel Osborn, to a Belgian hospital at Bruges, but many more, and some of very good workmanship, remained. Mostly they were old-fashioned but of excellent steel and make. He instanced some knives by famous makers, and thought that metal might be substituted for the wooden handles, when they would be serviceable instruments to-day.

An article published in *Le Belge Indépendant* was received by the Committee describing the establishment of the dispensary in Aldwych for the Belgian refugees at the opening of the war and the foundation of La Société Belge de Médecine en Angleterre. Dr. Clément Philippe, with the assistance of Dr. J. H. Philpot and Dr. H. A. Philpot, organised the former movement, and for some time the Drs. Philpot and Dr. Des Vœux, with the assistance of certain refugee Belgian doctors, carried on very useful work. It may be remembered that this work was afterwards transferred to the Metropolitan Asylums Board, and now that the Belgian doctors are returning to their homes the Board will continue its supervision over the remaining patients. The article also described the preliminary circumstances which led to the establishment of the Belgian Doctors' and Pharmacists' Relief Fund. This Fund came into being upon representations made, by Dr. Charles Jacobs mainly, to the Editors of THE LANCET and the *British*

Medical Journal, and the article in *Le Belge Indépendant* bears witness to the generosity of the members of the British professions, by whom some £25,000 has been subscribed, the bulk of which has been expended on Belgian sufferers in Belgium.

As just sufficient money remained in hand it was decided to send to Belgium the full mensuality of £800 for next month.

The following subscriptions have been received:—

PARIS.

(FROM OUR OWN CORRESPONDENTS.)

Diet Kitchens for Military Hospitals.

AN interesting experiment in the organisation of diet kitchens has been made during the last two years in French military hospitals. Begun in a tentative way to meet an obvious need in one of those hastily improvised establishments dotted about the provinces in the early days of the war, the experiment has now crystallised into a definite work of undoubted importance in the caring for the sick and wounded, and will possibly form the basis of a radical change in the dietary treatment of hospital patients throughout France.

Even before the war the food given to the patients in French civilian hospitals was bad enough to justify the writer of a Paris guide-book in stating that "the catering is the worst possible. patients being fed almost exclusively on a beef diet with vegetables, mostly of the dried order, beef being given three times a day in the form of soup once and boiled beef twice." The war naturally aggravated these conditions, and in many of the hurriedly organised military hospitals the cooking was entrusted to unskilled people whose knowledge of catering for large numbers of wounded was sadly deficient.

The initial difficulties of this new phase of hospital administration were hard to overcome, but a reform movement was supported by General Rouget, the Director-General of the Service de Santé, Dr. Mourier, the under-secretary, Mr. Joseph Reinach, and many highly-placed persons, and the scheme from a small beginning is now assuming a definite importance. One difficulty lay in the fact that the cooks in military hospitals are nearly always soldiers; and in France a soldier is theoretically supposed to be master of all trades, and credited with a superhuman versatility, while his military duties come before all others. A woodcutter or a bricklayer may be detailed to do the cooking for several hundred men, and when he gained a working knowledge of the job he may be moved to the other side of France for purely military reasons to attend the stoking of furnaces in a dépôt. It was realised that while the food supply was quite adequate, everything was spoiled by this use of unskilled labour, and that the only remedy lay in the appointment of specially trained cooks working under a surveillante.

Early in January, 1917, Miss M. Oliver, daughter of the late Dr. George Oliver, received permission from the French Service de Santé to open the first diet kitchen of the "Service des Régimes" at Hospital No. 75 at Vichy. Two ladies took charge of the cooking with some voluntary help in the distribution. The hospital was the medical centre of the 13th Region, and offered a good deal of variety in the clinical work, so the workers gained much experience in satisfying the individual needs of each case. The work was carried on till the following July, when the hospital was taken over by the Americans. By May the Government authorisation had been gained for starting a diet kitchen at the Villemin Hospital in the rue des Récollets, Paris. At that time there were there about 500 beds. The majority of the cases were tuberculous, and the diet kitchen was opened for these and for two wards of abdominal cases.

Two months later a diet kitchen was started by two lady workers in the Val-de-Grâce Hospital, the oldest and biggest military hospital in France, principally to provide additional purées and soups for Dr. Morestin's famous surgical division of wounded in head, jaw, and throat. As

these men can only be fed through tubes, it is particularly necessary that attention should be paid to the assimilative qualities and to the nutritive value of the food. The success of this experiment was so marked that in November the work was enlarged so as to include the whole hospital: a large refectory was turned over to the Service des Régimes, as the diet kitchens are called, and fitted up by the hospital authorities with a range, two gas stoves, and every up-to-date contrivance for a model kitchen. The whole of the 14 divisions of this great hospital, as well as the annexe containing another large division of head, jaw, and throat cases, is now provided with special diet, when necessary, by the diet kitchen.

The next experiment was made at Epernay, where a diet kitchen was opened on Jan. 1st, 1918, in the principal bone fracture hospital in France. Unluckily, the German offensive in June put a stop to the excellent results obtained by the extra nourishment given through the diet kitchen, for the entire hospital had to be evacuated to a field ambulance far behind the lines—the kitchen was trampled down and the outfit scattered. The hospital will, however, soon go back to its old quarters when the diet kitchen will be re-established. A fifth diet kitchen was opened in the Le Vénet Hospital, near Paris, on July 1st, 1918, where the work done in providing gassed patients with suitable nourishment has saved many lives. Diet kitchens have also been well started in St. Jacques Hospital, at Besançon, and in the military hospitals at Troyes and Reims. The working of the diet kitchens in each case is practically identical. The directress of the work goes round the wards and notes the diet cards filled in by the doctor, and measures out the quantity of food required by each case. The cooking is done by paid workers under the supervision of the directress. The regular hospital fire is provided by the authorities, but the expense of the special diet is covered by Miss Oliver's "Service des Régimes," which also pays the salaries of the workers.

The excellent results shown since the establishment of these kitchens have evoked unrestricted appreciation from the doctors in charge of the hospitals, as well as of the heads of the French Service de Santé. The success is so notable that Miss Oliver is now hoping to develop her work so as to provide every hospital in France with a Service des Régimes. The only difficulty is the lack of funds. Once this is overcome, and each hospital has its special diet kitchen, Miss Oliver wants to coöperate with the "Service de Santé" in the formation of a "Service de Cuisine," where women cooks and women inspectors might be trained to specialise in hospital cookery.

French authorities, with a fine defiance of Voltaire, have welcomed this practical aid, and the endowment of every military hospital with a properly organised "Service de Cuisine" will form one more link in the friendship between England and France.

Medical Demobilisation in France.

Dr. Mourier, Under Secretary of State for the Service de Santé, has already made some progress with demobilising his own department. Red Cross hospitals have been dealt with first, and in Paris alone eight closed their doors last week. A knotty point is the allocation of the enormous accumulation of surgical material. As regards beds and furniture, the proposal is to devote them to help rehabilitate the devastated communes in the north of France. Medical officers themselves belonging to the earliest classes will be demobilised at once and replaced by more recent classes, who will as far as possible be detailed to their own districts, where they can get in touch with their practices. On demobilisation pay will be continued for some little time. Those who desire to remain will be retained in the services, as well as a certain number of indispensables. In Paris the larger proportion of consultants attached to military hospitals have asked to continue their work.

Influenza in France.

Influenza, which seemed to be dying out, has had a new lease of life the last three weeks with the prolongation of the warm moist weather. The number of severe and fatal cases has, however, been much smaller than two months ago. Disinfection leaves much to be desired on account of shortness of sanitary staff. A wealth of new suggestions for treatment have been made to the Academy of Medicine and other learned societies. M. Armand Gautier has advised the

injection of quinine and arnéual dissolved in normal saline. M. Albert Robin has obtained excellent results with this remedy. M. Sou de Rouville and M. Netter have used inoculations of oxide of tin in colloidal suspension. They have had success in certain desperate cases, observing that the inoculations have produced the maturing of fixation abscesses, provoked by turpentine injection after the method of Fochier, in cases in which such injections had evoked no reaction—a condition tantamount to a fatal prognosis. Finally, MM. Grigant and Moutier have employed injections of blood serum from patients convalescent of influenza, obtaining remarkable results when the injections were given practically from the onset of the fever.

Maternal and Infantile Protection in Paris during the War.

A central office was set up in Paris at the outset of the war to assure protection for necessitous mothers and infants in Paris and its neighbourhood in intimate relation with all the maternities and with every local authority. M. Pinard recently reported to the Academy on the work done by this central office. More than 100,000 mothers and babies have received assistance during the last four years. In the last year of all 31,262 mothers claimed help before, during, or after their confinement, a large proportion of the 34,125 births registered in Paris. Australia's contribution to the work has been invaluable. From Dec. 18th, 1915, to June 22nd, 1918, the Franco-Australian League at Sydney remitted to Mme. Michel, honorary president of the work, a sum of more than 150,000 fr., and the same League at Melbourne a total of 550,000 fr., for which M. Pinard in his report tenders the warmest thanks. Mortality in Paris during the first year of post-natal life has sensibly diminished in the last 12 months; from 155 per 1000 births in 1914 the figure has fallen to 140, or less than what it was before the war. Deaths due to enteritis fell from 1363 in 1914 to 762 in 1918, a result attributed to the increase of breast-feeding and to the special cow's milk reserved by the Government for hand-fed infants. Congenital debility has, alas, increased as a cause of early death in the last two years. This mortality stands in close relation to the exhaustion of the mothers by arduous work, a condition which did not exist in the first year of the war.

French Doctors and the Excess Profits Tax.

A considerable levy has been made on war profits in all professions. The Association of Medical Societies of France has recently held a reunion at which the unanimous demand was made for the exemption of the medical corps from the tax. Except in the rarest cases the medical profession has, it is alleged, during the war only made paltry profits, since the overwhelming proportion has been mobilised and of the remainder most have given much of their time gratuitously to Red Cross work. The question has been submitted to the highest financial authority, but should its decision be unfavourable to the doctors the Association has decided to memorialise the Council of State, asking that the basis of fiscal control should be the medical man's ledger, the production of which is now contrary to the law of professional secrecy.

Dec. 28th, 1918.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

The Influenza Scourge.

COMMENCING in late September, Canada has passed through a terrible epidemic of influenza. It is yet impossible to give any figures for the whole country, but the deaths in Toronto reached as high as 150 on one day. In Canada the disease has not been made reportable or notifiable and no quarantine has been practised, but isolation has been put into force to some extent by private practitioners and in hospitals. Toronto grappled with the epidemic by rapidly preparing two emergency hospitals, one of which has not been used. Toronto's health officer claims that that city reached the crest of the epidemic much earlier than other Canadian and American cities. Some physicians used a prophylactic vaccine and speak well of it, and the Ontario Board of Health participated in the making of such vaccine. That board discussed reporting, isolation, and quarantine in regard to influenza before the epidemic invaded the

province, but concluded that these measures were impracticable. There was much disruption of business and educational life, but, speaking generally, each municipality was left to its own resources in fighting the disease. Evidence is strong that the mass of the people still cling to alcohol in the treatment of influenza. In Prince Edward Island clergymen were empowered to write prescriptions for alcoholic liquors, and temperance laws were in general more plastic than at other times. In Toronto there are two licensed vendors of liquors under the Ontario Temperance Act, and the long lines of waiting citizens testified to the number of prescriptions written by physicians. The Montreal Board of Health had prepared a circular advising the public to take to bed and send for the physician at the first sign of the disease. In regard to vaccines, the public was informed that the treatment was still in an experimental stage, and that no body of medical opinion was prepared to endorse their use as a prophylactic measure. The opinion has been widely expressed that the epidemic of influenza "has taken a terrible fall out of" preventive medicine. It is scarcely understandable how medical officers simply waited for the inevitable.

Some Mental Statistics in Canada.

6931 patients were in the hospitals for insane in Ontario in one recent year, which would make in proportion 20,000 for all of Canada. Represented in money this would be an economic loss to Canada annually of more than \$16,300,000. While the exact numbers of the feeble-minded in Canada have not at any time been determined, in certain centres they have been, for in Toronto, with a population of more than 500,000, 2500 cases have been discovered; and figuring on this basis, approximately there are 36,000 mental defectives in the Dominion. The late Dr. Gilmour, parole officer for Ontario, estimated that 33 per cent. of prisoners in Ontario institutions were mentally abnormal. The Toronto General Hospital psychiatric clinic, in three years, had 1300 mental defectives referred to it by the juvenile court of that city. Thus, about 40 per cent. of the total number of children found guilty of repeated offences against the law are defective delinquents. Take prostitution at the venereal clinic in the same institution—between 50 and 75 per cent. of all the loose women are mentally defective. In one institution of the city that cares for girls of weak moral nature 90 per cent. of one hundred odd cases examined were of the feeble-minded order. Of 10,000 school children examined by Dr. Hincks, psychiatrist of the Board of Health, 2 per cent. were feeble-minded, and 100 of these were guilty of evil sexual practices.

Canadian Association for the Prevention of Tuberculosis: The Eighteenth Annual Report.

The secretary of this association (Dr. George D. Porter, Toronto) reports that nine years ago there were just six institutions in Canada for the care and treatment of the tuberculous. There was only one institution of this character west of Hamilton, Ontario, to the Pacific coast—in British Columbia—with 16 beds. Now there are ten institutions west of Hamilton, and a proportionate growth east of that city to Halifax and Prince Edward Island. The total accommodation throughout Canada nine years ago was about 350 beds; to-day it is about 3500. The association has abundantly justified its existence. The money spent in maintenance was about \$150,000 per annum; to-day it totals over \$900,000 per annum. Some \$3,000,000 have been spent in plants. The National Sanatorium Association was the pioneer organisation, and some interesting figures are given of it below. It has the largest number of patients. The first provincial sanatorium was established in Nova Scotia; and at Hamilton, Ontario, was erected the first local or county institution in all Canada.

The National Sanatorium Association.

The following institutions are controlled by this association: Muskoka Free Hospital for Consumptives, Muskoka Cottage Sanatorium (both near Gravenhurst, Ontario),¹ Toronto Free Hospital for Consumptives, King Edward Sanatorium for Consumptives, Queen Mary Hospital for Consumptive Children, Free Dispensary-Gage Institute, Toronto, the Sanatorium Club, the Weston Sanatorium Club. It has been a serious problem to manage all these institutions during the war period, owing to the advanced prices of foods

and the shortage of trained nurses. Four years ago, at the beginning of the war, the daily average number of patients in residence was 485, now it is 688. The annual expenditure advanced in that time from \$275,000 to \$510,000; a conservative estimate for the present year's requirements is \$585,000. The per capita cost of maintenance in the Muskoka and Weston institutions advanced from \$10.50 to \$14.52 per week. For the present year \$55,000 has been received from appeals to the public, and for the past hospital year the expenditure for maintenance exceeded the income by \$52,000. The doors of these institutions are open to residents of the province of Ontario, and during the past hospital year they have cared for 1707 patients, making a total of 11,679 cared for in all the hospitals since establishment.

Tuberculosis Toll in Canada.

Almost as many people died in Canada of tuberculosis during the four years and three months of war as there were Canadian soldiers killed in battle in the same period. It is also claimed that as many civilians at home were stricken with the disease as the number of soldiers who went overseas. Dr. Harding, the secretary of the Royal Edward Institute, Montreal, has made this statement. During the past hospital year of that institution 11,000 patients had consulted the dispensary, and there had been 1063 new patients, of whom 391 were found on examination to be tuberculous. Two hundred and forty soldiers had been treated in the military annexe, preparatory to being sent to Ste. Agathe Sanatorium. Some of these were advanced and hopeless cases, and 21 of them had died of the disease.

New Military College.

The National Cash Register Building in Toronto, which was purchased by the Canadian Government a short time ago for an orthopaedic hospital, will probably be opened early in 1919. It is to be the centre for orthopaedic work in Canada and will also be used for teaching clinical orthopaedics. It is to accommodate from 1500 to 2000 and is equipped with all modern apparatus. The hospital will have an assembly hall to accommodate 850.

Toronto, Dec. 20th, 1918.

URBAN VITAL STATISTICS.

VITAL STATISTICS OF LONDON DURING NOVEMBER, 1918.

In the accompanying table will be found summarised statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to an annual rate of 4.0 per 1000 of the population, estimated at 4,026,901 persons; in the three preceding months the rates had been 3.2, 4.7, and 5.9 per 1000. Among the metropolitan boroughs the lowest rates from these notified diseases were recorded in St. Marylebone, Hampstead, the City of London, and Greenwich; and the highest rates in Bethnal Green, Poplar, and Southwark. The prevalence of scarlet fever was 29 per cent. lower than in the preceding month; this disease was proportionately most prevalent in Bethnal Green, Poplar, Southwark, Bermondsey, and Lambeth. The Metropolitan Asylums Hospitals contained 1107 scarlet fever patients at the end of the month, against 690, 931, and 1184 at the end of the three preceding months; the weekly admissions averaged 146, against 101, 164, and 178 in the three preceding months. The prevalence of diphtheria was 32 per cent. lower than in October; the greatest prevalence of this disease was recorded in Stoke Newington, Hackney, Stepney, Poplar, and Southwark. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 886, 1051, and 1155 at the end of the three preceding months, had declined to 1000 at the end of November; the weekly admissions averaged 129, against 107, 166, and 169 in the three preceding months. The prevalence of enteric fever declined 60 per cent. compared with the previous month; of the 16 cases notified 4 belonged to the City of Westminster, 3 to Fulham, and 2 each to Greenwich and Woolwich. There were 33 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 32, 43, and 56 at the end of the three preceding months; the weekly admissions averaged 3, against 6, 6, and 9 in the three preceding months. Erysipelas was proportionately most prevalent in St. Pancras, Shoreditch, Bethnal Green, Poplar, and Bermondsey. Of the 5 cases of puerperal fever notified during the month 2 belonged to Lambeth: 4 cases of cerebro-spinal meningitis were notified from Islington; and 1 of poliomyelitis from Poplar.

The mortality statistics in the table relate to the deaths of civilians belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased had previously resided. During the four weeks ended Nov. 30th the deaths of 13,061 London residents were registered, equal to an annual rate of 42.3 per 1000; in the three preceding months the rates had been 10.1, 11.4, and 27.3 per 1000. The death-rates ranged from 27.7 in Hampstead, 28.5 in Lewisham, 28.9 in Stoke Newington, and 30.8 in Woolwich to 50.0 in Poplar, 51.7 in Southwark, 53.4 in Bermondsey, 56.5 in Finsbury, and 62.0 in Holborn. The 13,061 deaths from all causes included 211 which were referred to the

* Including membranous croup.

principal infectious diseases, and comprised 70 from infantile diarrhoea, 66 from diphtheria, 38 from measles, 17 from whooping-cough, 15 from scarlet fever, and 5 from enteric fever. No death from any of these diseases was recorded in Hampstead and only one in Paddington, in the City of Westminster, and in the City of London; the highest rates were recorded in Hammersmith, St. Marylebone, St. Pancras, Holborn, and Bethnal Green. The 38 deaths from measles were 43 below the average number in the corresponding period of the five preceding years, and included 8 each in Hammersmith and St. Pancras, 4 each in St. Marylebone and Camberwell, and 3 in Kensington. The 15 fatal cases of scarlet fever were 6 below the average, and included 3 each in Southwark and Lambeth, and 2 in Hackney. The 66 deaths attributed to diphtheria were 8 above the average, and included 8 in Lambeth, 7 in Hackney, 6 in Poplar, and 5 in Southwark. The deaths from whooping-cough numbered 17, and were 16 below the average; of these, 2 each belonged to Islington, Hackney, Stepney, Bermondsey, and Lambeth. The 5 fatal cases of enteric fever were 4 below the average, and included 2 in Hammersmith. The 70 deaths from infantile diarrhoea were 67 below the average, and included 11 in Islington, 7 each in Stepney and St. Marylebone, and 5 in Woolwich. In conclusion, it may be stated that the aggregate mortality from these principal infectious diseases in London during November was 38 per cent. below the average.

(Week ended Dec. 14th, 1918.)

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 16.4, against 23.7 and 19.8 per 1000 in the two preceding weeks. Of the 756 deaths from all causes, 18 were classified to influenza, which was also stated as a secondary cause in 108 deaths classified to other diseases; in the previous week these numbers were 24 and 165 respectively. The 322 deaths in Glasgow corresponded to an annual rate of 15.1 per 1000, and included 6 from infantile diarrhoea, 4 from whooping-cough, and 2 from diphtheria. The 103 deaths in Edinburgh were equal to a rate of 16.1 per 1000, and included 2 from diphtheria and 1 from whooping-cough.

(Week ended Dec. 21st, 1918.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality was 16.8 per 1000, against rates declining from 36.5 to 20.2 per 1000 in the three preceding weeks. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was 16.0, or 2.2 per 1000 below that recorded in the previous week; among the remaining towns the rates ranged from 4.0 in Swindon, 5.1 in Hornsey, and 7.2 in Ipswich, to 27.9 in Dewsbury, 32.8 in West Hartlepool, 41.2 in Sunderland, and 48.9 in Barnsley. The principal epidemic diseases caused 154 deaths, which corresponded to an annual rate of 0.5 per 1000, and included 52 from infantile diarrhoea, 47 from diphtheria, 21 from whooping-cough, 17 from measles, 13 from scarlet fever, and 4 from enteric fever. Diphtheria caused a death-rate of 1.1 in Liverpool and 2.9 in Oxford. The deaths from influenza, which had declined from 7557 to 1885 in the six preceding weeks, further fell to 1014, and included 186 in London, 68 in Birmingham, 55 in Manchester, 43 in Liverpool, 32 in

Bristol, and 31 in Sunderland. There were 2 cases of small-pox, 1030 of scarlet fever, and 1056 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital; the two latter were 59 below and 39 above the respective numbers remaining at the end of the previous week. The causes of 41 deaths in the 96 towns were uncertified, of which 8 were registered in Birmingham, 6 in Liverpool, and 3 in Gateshead.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 14.8, against rates declining from 24.3 to 16.4 per 1000 in the four preceding weeks. Of the 683 deaths from all causes, 7 were classified to influenza, which was also stated as a secondary cause in 74 deaths classified to other diseases; in the previous week these numbers were 18 and 108 respectively. The 299 deaths in Glasgow were equal to a rate of 14.0 per 1000, and included 4 each from diphtheria and infantile diarrhoea, and 1 from whooping-cough. The 81 deaths in Edinburgh were equal to a rate of 12.7 per 1000, and included 3 each from scarlet fever and whooping-cough, and 1 from diphtheria.

Irish Towns.—The 145 deaths in Dublin corresponded to an annual rate of 18.9, or 3.1 per 1000 below that recorded in the previous week, and included 14 from influenza, 2 from infantile diarrhoea, and 1 from measles. The 145 deaths in Belfast were equal to a rate of 19.2 per 1000, and included 2 from infantile diarrhoea and 1 from diphtheria.

(Week ended Dec. 28th, 1918.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had declined from 36.5 to 16.8 in the four preceding weeks, further fell to 14.8 per 1000. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was 13.8, or 2.2 per 1000 below that recorded in the previous week; among the remaining towns the rates ranged from 6.0 in Darlington, 7.3 in Enfield, and 7.6 in Ilford, to 28.1 in Sunderland, 27.3 in Bootle, 28.2 in Bury, and 45.7 in Barnsley. The principal epidemic diseases caused 137 deaths—the lowest number recorded in any week of the year; this number corresponded to an annual rate of 0.4 per 1000, and included 45 from infantile diarrhoea, 35 from diphtheria, 22 from measles, 13 from whooping-cough, 13 from scarlet fever, and 4 from enteric fever. The deaths from influenza, which had steadily declined from 7557 to 1014 in the seven preceding weeks, further fell to 581, and included 95 in London, 44 in Liverpool, 39 in Manchester, 25 in Birmingham, and 24 in Barnsley. There were 2 cases of small-pox, 1101 of scarlet fever, and 1105 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital; the two latter were 71 and 49 above the respective numbers remaining at the end of the previous week. The causes of 38 deaths in the 96 towns were uncertified, of which 10 were registered in Liverpool, 5 in Birmingham, and 3 in Gateshead.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 16.1, against rates declining from 24.3 to 14.8 per 1000 in the five preceding weeks. Of the 744 deaths from all causes, 6 were classified to influenza, which was also stated as a secondary cause in

(Continued at foot of next column.)

The War and After.

DEMobilISATION OF THE BRITISH RED CROSS.

We have received from Sir Arthur Stanley, chairman of the Joint War Committee of the British Red Cross: Lord Plymouth, vice-chairman of the Joint Committee; Sir Robert Hudson, chairman of the Joint Finance Committee; and Mr. E. A. Riddale, chairman of the Central Demobilisation Board, a statement on the financial position of the Red Cross, which begins to be demobilised with the New Year. The signatories ask that all collections in this country may be wound up and remitted to the Joint War Committee by the end of January, and those from overseas not more than a month later. The annual report of the Finance Committee will appear shortly.

THE CASUALTY LIST.

THE names of the following medical officers appear among the casualties announced since our last issue:—

Died.

Capt. H. R. Lawrence, M.C., South African M.C., qualified at Edinburgh in 1908, and was in practice at Newlands, Cape Province, South Africa, when war broke out. He at once volunteered for service, which he did in German South-West Africa, in England, and in France. He died in France of pneumonia.

Capt. A. J. Milne, South African M.C., qualified at Aberdeen in 1901, and was at one time M.O.H. of Mauritius. At the time of joining the Expeditionary Force he was acting M.O.H. of Johannesburg.

Wounded.

Lieut. M. S. Ullah, I.M.S.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported:—

Capt. H. R. Lawrence, M.C., South African M.C., died from pneumonia, only son of the late Dr. T. G. Lawrence, of George, S. Africa.

Lieut. E. A. F. Hawke, Royal Field Artillery, died at Woolwich, son of Dr. E. D. H. Hawke, of Shortlands, Kent.

Flight Capt. E. R. H. Beaman, R.A.F., killed in an aeroplane collision, son of the late General A. H. Beaman, I.M.S.

THE HONOURS LIST.

A long list of promotions and awards for valuable services rendered in connexion with military operations in the field and in connexion with the war was issued on Wednesday. We give here some of the awards to medical officers, and the remainder will be given in our next issue:—

K.C.B. (Military Division).

Maj.-Gen. (temp. Lt.-Gen.) C. H. Burtchall, C.B., C.M.G., K.H.S., A.M.S.

C.B. (Military Division).

Col. C. A. Young, C.M.G., A.M.S.; Temp. Col. A. Fullerton, C.M.G., A.M.S.; Temp. Col. H. A. Ballance, A.M.S.; Col. T. P. Jones, C.M.G., A.M.S.; Maj.-Gen. R. C. Munday, R.A.F.

C.B. (Civil Division).

Surg.-Capt. W. G. Axford, R.N.; Surg.-Capt. A. S. Nance, R.N.

K.C.M.G.

Surg. Rear-Admiral G. Welch, C.B.

C.M.G.

Temp. Col. (Maj., R.A.M.C.) G. E. Gask, D.S.O., A.M.S.; Col. J. Poe, D.S.O., A.M.S.; Temp. Col. J. A. Nixon, A.M.S.; Temp. Col. (Lt.-Col., R.A.M.C., T.F.) W. H. Hume, A.M.S.; Lt.-Col. W. K. Clayton, T.D., R.A.M.C., T.F.; Lt.-Col. (temp. Col.) A. J. MacDougall, R.A.M.C.; Lt.-Col. (temp. Col.) H. G. Martin, R.A.M.C.; Lt.-Col. (temp. Col.) S. de C. O'Grady, D.S.O., R.A.M.C.; Lt.-Col. (temp. Col.) H. Herrick, D.S.O., R.A.M.C.; Lt.-Col. (temp. Col.) H. S. Roch, D.S.O., R.A.M.C.;

(Continued from preceding column.)

50 deaths classified to other diseases; in the previous week these numbers were 7 and 74 respectively. The 355 deaths in Glasgow corresponded to an annual rate of 16.6 per 1000, and included 8 from whooping-cough, 6 from diphtheria, 3 from infantile diarrhoea, and 2 from scarlet fever. The 94 deaths in Edinburgh were equal to a rate of 14.7 per 1000, and included 5 from whooping-cough and 1 from diphtheria.

Irish Towns.—The 156 deaths in Dublin corresponded to an annual rate of 20.4, or 1.5 per 1000 above that recorded in the previous week, and included 9 from influenza, 4 from infantile diarrhoea, and 1 from measles. The 146 deaths in Belfast were equal to a rate of 19.4 per 1000, and included 2 from infantile diarrhoea and 1 from diphtheria.

Temp. Hon. Lt.-Col. H. Cabot, R.A.M.C.; Temp. Maj. (acting Lt.-Col.) J. Dalrymple, O.B.E., R.A.M.C.; Col. R. P. Wright, D.S.O., Canadian A.M.C.; Lt.-Col. S. Campbell, Canadian A.M.C.; Lt.-Col. J. F. Kidd, Canadian A.M.C.; Col. J. A. Dick, Australian A.M.C.; Lt.-Col. O. J. Martin, Australian A.M.C.; Col. D. J. McGavin, D.S.O., N. Zealand M.C.; Lt.-Col. D. N. W. Murray, D.S.O., N. Zealand M.C.; Surg.-Comdr. R. D. Jameson, R.N.; Surg.-Comdr. H. S. Burniston, R.N.

K.B.E. (Military Division).

Temp. Col. Sir A. E. Wright, Kt., C.B., F.R.S., A.M.S.; Col. (temp. Maj.-Gen.) S. Hickson, C.B., A.M.S.

MENTIONED IN DESPATCHES.

The names of the following medical officers are mentioned for distinguished and gallant services and devotion to duty in a despatch, dated Nov. 8th, 1918, received from the Commander-in-Chief of the British Armies in France:—

ARMY MEDICAL SERVICE: STAFF.

Lt.-Col. (temp. Col.) H. P. W. Barrow, C.M.G., D.S.O., R.A.M.C.; Lt.-Col. (temp. Col.) W. Bennett, D.S.O., R.A.M.C.; Col. E. W. Bliss, O.M.G., D.S.O.; Capt. and Bt. Maj. (acting Maj.) L. G. Bourdillon, D.S.O., M.C., R.A.M.C.; Lt.-Col. (temp. Col.) G. W. Brazier-Osagah, C.B., C.M.G., R.F.; Lt.-Col. (temp. Col.) B. E. Burke, D.S.O.; Maj.-Gen. (temp. Lt.-Gen.) C. H. Burtchall, O.B., C.M.G.; Maj.-Gen. H. Carr, C.B.; Capt. (acting Maj.) S. J. Clegg, R.A.M.C. (T.F.); Lt.-Col. (temp. Col.) H. Collinson, C.M.G., D.S.O., R.A.M.C. (T.F.).

Capt. (acting Maj.) W. H. Davison, R.A.M.C. (T.F.); Capt. (acting Maj.) T. I. Dun, M.C., R.A.M.C.

Capt. and Bt. Maj. (temp. Maj.) G. W. Ellis, R.A.M.C. (T.F.); Lt.-Col. (temp. Col.) O. W. A. Elsner, D.S.O.

Lt.-Col. (temp. Col.) H. B. Fawcous, C.M.G., D.S.O.; Lt.-Col. (temp. Col.) T. Fraser, D.S.O., R.A.M.C. (T.F.); Lt.-Col. (temp. Col.) R. S. H. Fuhr, C.M.G., D.S.O., R.A.M.C.

Lt.-Col. (temp. Col.) J. S. Galle, C.M.G., D.S.O.; Maj. (temp. Col.) G. E. Gask, D.S.O.; Capt. (acting Maj.) G. F. P. Gibbons, R.A.M.C. (S.R.); Col. H. W. Grattan, D.S.O.; Temp. Capt. A. H. Greg, R.A.M.C.

Lt.-Col. (temp. Col.) J. A. Hartigan, C.M.G., D.S.O., R.A.M.C.; Lt.-Col. (acting Col.) H. Herrick, D.S.O.; Lt.-Col. (acting Col.) H. Hewetson, D.S.O., R.A.M.C.; Col. (temp. Maj.-Gen.) S. Hickson, C.B.; Maj. (temp. Lt.-Col.) F. D. G. Howell, D.S.O., M.C.; Col. W. M. Hudleston, C.M.G., D.S.O.

Col. (temp. Maj.-Gen.) Sir J. M. Irwin, K.C.M.G., C.B.

Col. T. P. Jones, C.M.G.

Lt.-Col. (temp. Col.) L. N. Lloyd, C.M.G., D.S.O.

Lt.-Col. (temp. Col.) A. J. MacDougall; Capt. (acting Maj.) E. B. Marsh; Lt.-Col. (temp. Col.) H. G. Martin; Lt.-Col. (temp. Col.) F. McLennan, R.A.M.C.; Temp. Capt. (acting Maj.) L. Meakin; Col. (temp. Maj.-Gen.) S. G. Moores, C.B., C.M.G.

Capt. (temp. Col.) J. A. Nixon.

Col. D. M. O'Callaghan, C.M.G.; Capt. (acting Maj.) B. A. Odium, R.A.M.C.; Lt.-Col. (temp. Col.) S. de C. O'Grady, D.S.O.; Maj.-Gen. Sir M. W. O'Keefe, K.C.M.G., C.B.; Lt.-Col. and Bt. Col. G. J. A. Ormsby, D.S.O., R.A.M.C.

Capt. (acting Maj.) M. W. Paterson, M.C., R.A.M.C. (S.R.); Col. R. H. Penton, D.S.O., R.A.M.C.; Col. J. Poe, D.S.O.; Lt.-Col. (temp. Col.) J. Powell, D.S.O.; Col. O. W. Proffitt, C.M.G., D.S.O.; Col. H. V. Pryne, D.S.O., R.A.M.C.

Capt. (acting Maj.) A. L. Robertson; Lt.-Col. (temp. Col.) H. S. Roch, D.S.O., R.A.M.C.; Maj. (temp. Col.) D. Rorie, D.S.O.; Capt. (acting Maj.) W. H. Rowell; Maj. and Bt. Lt.-Col. (temp. Lt.-Col.) E. Ryan, C.M.G., D.S.O.

Lt.-Col. (temp. Col.) A. H. Safford; Maj. G. F. Sheehan, D.S.O.; R.A.M.C.; Lt.-Col. (temp. Col.) J. P. Silver, D.S.O., R.A.M.C.; Col. E. W. Slayter, C.M.G., D.S.O.; Temp. Capt. (acting Maj.) G. W. Smith; Temp. Col. A. B. Soltau, C.M.G.; Lt.-Col. R.A.M.C. (T.F.).

Col. G. St. C. Thom, C.B., C.M.G.; Lt.-Col. (temp. Col.) A. G. Thompson, C.M.G., D.S.O.; Maj.-Gen. H. N. Thompson, C.B., C.M.G., D.S.O.; Col. (temp. Maj.-Gen.) J. Thomson, C.B.; Col. H. S. Thurston, C.B., C.M.G.

Capt. (temp. Maj.) J. Walker, M.C., R.A.M.C. (S.R.); Capt. (acting Maj.) W. L. Webster; Lt.-Col. (temp. Col.) B. F. Wingate, D.S.O., R.A.M.C.; Capt. (temp. Maj.) A. E. Wright, D.S.O.

Col. C. A. Young, C.M.G.

CONSULTANTS.

Temp. Col. H. A. Ballance; Temp. Maj.-Gen. Sir J. R. Bradford, K.C.M.G., C.B., F.R.S.; Temp. Col. A. Fullerton, C.M.C.; Temp. Maj.-Gen. Sir W. P. Herringham, C.B.; Temp. Lt.-Col. G. M. Holmes, C.M.G.; Temp. Col. W. B. Hume; Temp. Col. W. T. Lister, C.M.G.; Temp. Maj. (acting Lt.-Col.) H. MacCormac; Temp. Col. S. M. Smith, C.B.; Temp. Col. Sir A. B. Wright, C.B., F.R.S.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. W. J. P. Adye-Curran; Temp. Capt. (acting Maj.) J. Alexander; Capt. (acting Maj.) J. A. Andrews, M.C.; Temp. Capt. (acting Major) W. B. G. Angus, M.C.; Temp. Capt. (acting Maj.) J. S. Arkle.

Temp. Lt.-Col. J. L. Birley; Temp. Capt. (acting Maj.) A. J. Blake, M.C.; Capt. and Bt. Maj. (acting Lt.-Col.) H. H. Blake; Temp. Capt. W. H. Blakemore; Temp. Capt. (acting Maj.) L. R. Broster; Temp. Capt. (acting Lt.-Col.) L. G. Brown, M.C.; Maj. and Bt. Lt.-Col. (acting Lt.-Col.) C. G. Browne, D.S.O.; Maj. (temp. Lt.-Col.) R. A. Bryden, D.S.O.

Temp. Hon. Lt.-Col. H. Cabot; Capt. (acting Maj.) N. Cantile, M.C.; Maj. (acting Lt.-Col.) J. C. G. Carmichael; Temp. Capt. H. H. Carter; Capt. (acting Lt.-Col.) F. Casement, D.S.O.; Temp. Capt. (acting Maj.) R. Charles; Temp. Capt. T. Clapperton; Temp. Capt. N. A. Coward; Temp. Capt. R. L. Crabb; Temp. Capt. R. Crothers.

Temp. Lt.-Col. J. Dalrymple, O.B.E.; Temp. Capt. (acting Maj.) W. S. Danks; Maj. (temp. Lt.-Col.) H. A. Davidson, D.S.O.; Temp. Maj. R. Dick; Temp. Maj. W. S. Dickie; Temp. Capt. F. Dillon; Maj. (temp. hon. Lt.-Col.) G. Dreyer.

Maj. (acting Lt.-Col.) C. T. Edmunds; Temp. Capt. E. F. Emswiler, D.S.O.; Temp. Capt. J. E. English; Capt. (acting Lt.-Col.) T. S. Eves, D.S.O.

Lt.-Col. (acting Col.) F. G. Fitzgerald, D.S.O.; Capt. W. Foot, M.C.; Maj. (acting Lt.-Col.) W. H. Forsyth; Maj. J. R. Foster; Temp. Maj. T. M. Frood.

Temp. Capt. D. S. Graham; Temp. Maj. (acting Lt.-Col.) G. D. Gray; Temp. Capt. H. A. Grierson; Capt. J. H. Gurley.

Temp. Hon. Capt. F. Hall; Maj. (temp. Lt.-Col.) P. J. Hanafin, D.S.O.; Temp. Capt. C. G. Harmer; Capt. (acting Maj.) W. C. Hartgill, M.C.; Maj. (temp. Lt.-Col.) T. E. Harty, D.S.O.; Temp. Capt. (acting Maj.) J. H. Hebb; Capt. (acting Lt.-Col.) C. Helm, M.C.; Temp. Capt. W. J. Henry; Temp. Capt. S. P. Hodgkinson; Temp. Hon. Maj. T. Houston; Capt. (acting Lt.-Col.) I. R. Hudleston; Temp. Capt. J. B. Hunter, M.C.

Temp. Capt. (acting Maj.) R. C. Irvine.

Temp. Capt. T. B. Johnstone.

Capt. A. White; Maj. (acting Lt.-Col.) G. F. Whyte; Maj. (acting Lt.-Col.) P. G. Williamson, M.C.; Capt. (acting Lt.-Col.) T. B. Wolstenholme.

Capt. (acting Lt.-Col.) J. Young.

CANADIAN ARMY MEDICAL CORPS.

Maj. (acting Lt.-Col.) W. A. G. Bauld; Lt.-Col. R. A. Bowie; Lt.-Col. E. H. Brown; Capt. M. G. Brown; Lt.-Col. P. G. Brown; Maj. J. F. Burgess; Lt.-Col. S. Campbell; Capt. G. F. Denyes; Lt.-Col. A. S. Donaldson, D.S.O.; Hon. Capt. J. A. Dougan; Capt. (acting Maj.) G. J. Gillam; Capt. J. Graham; Capt. S. E. Holmes; Lt.-Col. J. F. Kidd; Capt. W. J. MacKenzie; Capt. T. A. Malloch; Lt.-Col. B. Maxwell; Maj. R. J. McEwen; Maj. D. W. McKechnie, D.S.O.; Lt.-Col. H. E. Munroe; Lt.-Col. T. J. F. Murphy, D.S.O.; Maj. H. Orr; Maj. S. G. Ross, D.S.O., M.C.; Lt.-Col. E. Seaborn; Capt. A. H. Veitch; Lt.-Col. C. W. Vipond; Capt. R. E. A. Weston; Capt. T. Whitmore (died of wounds); Maj. (acting Lt.-Col.) J. H. Wood.

AUSTRALIAN ARMY MEDICAL CORPS.

Maj. A. W. H. a'Court; Maj. H. I. Carlile; Lt.-Col. R. W. Chambers; Maj. A. J. Collins, D.S.O., M.C.; Lt.-Col. W. E. L. H. Crowther; Col. J. A. Dick; Lt.-Col. (temp. Col.) T. P. Dunhill; Maj. C. N. Finn; Lt.-Col. H. K. Fry, D.S.O.; Lt.-Col. A. H. Gibson; Capt. A. J. de S. Howard; Lt.-Col. A. F. Jolley; Maj. F. D. H. B. Lawton; Maj. (temp. Lt.-Col.) F. N. Le Messurier, D.S.O.; Maj. G. B. Lowe; Lt.-Col. G. W. MacArthey; Maj. (temp. Lt.-Col.) A. F. MacLure; Lt.-Col. C. J. Martin, F.R.S.; Maj. A. McKillop; Maj. J. B. Metcalfe, D.S.O., M.C. (died of wounds); Maj. C. Morlet; Maj. W. A. Morton; Maj. J. D. Norris; Capt. S. V. O'Regan, M.C.; Maj. V. W. Savage; Maj. W. C. Sawers; Maj. (temp. Lt.-Col.) V. O. Stacy; Maj. D. MacD. Steele, M.C.; Maj. R. St. C. Steuart; Maj. L. G. Tassie, D.S.O.; Lt.-Col. W. G. D. Upjohn; Maj. F. L. Wall, M.C.; Lt.-Col. A. M. Wilson, D.S.O.

NEW ZEALAND MEDICAL CORPS.

Maj. F. T. Bowerbank; Lt.-Col. G. Craig; Maj. E. L. Marchant; Col. D. J. McGavin, D.S.O.; Lt.-Col. H. J. McLean; Lt.-Col. D. N. W. Murray, D.S.O.; Capt. Simcox.

SOUTH AFRICAN MEDICAL CORPS.

Capt. (acting Major) H. R. Mullins; Maj. M. S. Power, D.S.O.

AMERICAN MEDICAL CORPS.

Lt.-Col. R. H. Harte, Harvard Unit; Maj. R. I. Lee, Harvard Unit.

OBITUARY OF THE WAR.

DENIS COTTERILL, M.B., CH.B. EDIN., F.R.C.S. EDIN.,
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain D. Cotterill, who died of pneumonia following influenza on Dec. 2nd, at the age of 37 years, was eldest son of Lieutenant-Colonel J. M. Cotterill, C.M.G., consulting surgeon to Edinburgh Royal Infirmary. Educated at the Edinburgh Academy, he went on to Christ's College, Cambridge, where he spent two years in medical study. He completed his curriculum in Edinburgh, gaining distinction in pathology and surgery, and graduated in 1906. In 1910 he was elected a Fellow of the Royal College of Surgeons, Edinburgh, and took his seat as a Fellow during his father's presidency of the presidential chair. He was house surgeon under the late Professor Annandale, and on the Continent and in London and Liverpool studied surgery, especially in its orthopaedic aspects, in which he intended to specialise. On his return to Edinburgh Captain Cotterill began practice as a surgeon, acted as tutor in clinical surgery, and in 1913 was appointed an assistant surgeon to the Royal Infirmary.

In November, 1914, he went to France and was attached to No. 11 Stationary Hospital at Rouen, where he worked for some time, maintaining a high standard of surgical work. Later he resigned his appointment at Rouen, joined

the R.A.M.C., and was appointed to No. 50 Casualty Clearing Station, where, during the early days of the great advance and subsequent fighting, his unit was often working day and night without cessation. Captain Cotterill married in 1908 Miss Emily Roberts, and leaves a widow and two sons.

HERBERT GEORGE FLAXMAN SPURRELL, M.A.,
M.B., B CH. OXF.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain H. G. F. Spurrell, who died of pneumonia at the 19th General Hospital, Alexandria, on Nov. 8th, at the age of 41 years, was only son of the late Herbert Spurrell, of Eastbourne. Educated at Merton College, Oxford, where he gained the Welsh Memorial Prize in 1901 and took the M.A. degree, he qualified in 1907 from the London Hospital, taking the Diploma of the London School of Tropical Medicine in 1912. He was then Assistant Professor of Physiology at the University of New Orleans for a year, and held medical appointments in West Africa and South America, where he

indulged a passion for scientific research and discovered several new zoological species. One of these was a new species of West African rodent, *Anomalurus imperator*, a type of which he presented, together with a number of other rare and interesting West African mammals, to the British Museum. Whilst in Colombia he continued his zoological research, and during the first few months of his stay in the Choco brought together a series of batrachians and reptiles which

he presented also to the British Museum. A further important series of these animals was collected and presented by him in 1914, and in 1915 he discovered and presented a new limbless reptile (*Amphisbaena spurrelli*) and a new snake (*Herpetodryas vicinus*). In recognition of his work he was awarded the silver medal of the Zoological Society. On his return from Colombia in 1915 he was sent abroad by the Government on a secret mission, and in 1916-17 acted as Temporary Medical Officer at Obuss, S. Ashanti. In 1917 he took a commission in the R.A.M.C. and was employed on the R.A.F. Medical Board until his death. Besides his scientific monographs Captain Spurrell wrote a book on social evolution, entitled "Modern Man and His Forerunners," and a popular work on physiology.

Major D. D. JAMIESON, M.C., A.A.M.C., who met his death as the result of an aeroplane accident which occurred on July 18th, at the age of 39 years, was born at Kew, Melbourne. Educated at Hawthorn Grammar School, he graduated in medicine and surgery at Melbourne University in 1905, and practised at Perth, Fremantle, and Laverton Hospitals, and at Katoomba, N.S.W., and Stawell Hospital, Victoria. He joined the A.I.F. in July, 1915, and served for a short time in England before proceeding to Egypt. On his arrival in 1916 he joined the 2nd Light Horse Field Ambulance, and was awarded the Military Cross for gallantry and devotion to duty in the field at the Bir-el-Abd battle in September, and was mentioned in despatches. He acted as adjutant and was with his Brigade during all its operations in Sinai. In 1917 Major Jamieson was transferred to the 8th Light Horse as R.M.O., and remained with them until he proceeded to Port Said to await transport duty to Australia, where he met with the accident which resulted in his death. He was promoted to the rank of Major in November, 1916. He was associated with the 2nd Brigade and the 8th Light Horse Regiment in all the main engagements the Light Horse had undertaken since crossing the Suez Canal.

Obituary.

NOTTIDGE CHARLES MACNAMARA, F.R.C.S. ENG.,
F.R.C.S. IREL.,

CONSULTING SURGEON TO THE WESTMINSTER HOSPITAL.

Mr. N. C. Macnamara, who died on Nov. 21st, after a brief illness, at the advanced age of 86, retained to the end his keen and penetrating interest in life. He was a student at King's College, London, qualified with the Membership of the Royal College of Surgeons of England in 1854, and became almost immediately an assistant surgeon in the East India Company's service. On arrival in India he took charge of the First Bengal Fusiliers and before he had been many weeks at Dinapur was called upon to grapple with an appalling outbreak of cholera with only a few coolies to help him. Cholera remained for long a chief interest with him, and his "History of Asiatic Cholera" went through several editions and was translated into various languages. In the following two years Macnamara served in the Sonthal rebellion, and during the Indian Mutiny was officer of the Tirhut Volunteers until he was placed by the Viceroy in charge of the captive King of Oude. Later he became civil surgeon of Mirzapur and professor of ophthalmic surgery in the Calcutta Medical College. His ophthalmic work gained him widespread recognition, and the natives on whom he operated regarded him with veneration, while he was able to carry out in the face of great difficulties the desire of his heart to establish an ophthalmic hospital for the native poor of Calcutta. In 1866 he published a volume of lectures on Diseases of the Eye, of which a fifth edition appeared in 1891, while the year in which he became surgeon-major, 1873, was marked by the publication of "Lectures on Diseases of Bones and Joints," a third edition of which appeared in 1887. For three years he was editor of the *Indian Medical Gazette*.

In 1875 Macnamara obtained the F.R.C.S. Eng., and retiring from the service in the following year was appointed surgeon and lecturer on clinical surgery to the Westminster Hospital and surgeon to the Royal Westminster Ophthalmic Hospital, becoming consulting surgeon to both hospitals on his retirement from active work in 1897. He was elected a Fellow of the Royal College of Surgeons, Ireland, in 1887, and from 1885 to 1901 he was a member of the Council of the Royal College of Surgeons of England and Vice-President in 1893 and 1896. He was the Bradshaw lecturer, 1895, on Osteitis, and Hunterian orator in 1901, taking for his subject the Human Skull in Relation to Brain Growth. As a member of the British Medical Association he did much useful work, being a member of Council, chairman of several committees, Vice-President of the Section of Surgery at the annual meetings in 1881 and 1895, President of the Section of Ophthalmology in 1891, and treasurer of the Association from 1885 to 1887. He also took a keen interest in the work of the Royal Medical and Chirurgical Society and played a generous and active part in securing the house in Hanover-square, which it occupied for several years.

In addition to his contributions to medical literature, Mr. Macnamara wrote the articles on Cholera and Tetanus for the first edition of Quain's "Dictionary of Medicine," and those on Cholera and Leprosy in Davidson's "Hygiene and Diseases of Warm Climates," while two volumes of the "International Scientific Series," on the evolution of purposive living matter, are from his pen. His latest published book, "Instinct and Intelligence," which we reviewed in these columns at the beginning of 1916, was a plea for an alteration in our present system of education in which he sustained the thesis that "The animal side of man's nature results from a specific arrangement of elements entering into the formation of his central nervous system which he has inherited from his progenitors and cannot, therefore, get rid of or permanently alter."

Macnamara was one to whom work was a delight, and his numerous appointments did not prevent a considerable literary activity. Both were an expression of an overflowing physical energy. He revelled in outdoor exercise—hunting, shooting, and later golf. With a great dislike for formal entertaining he kept open house to all his friends. On reaching his seventieth year he retired into the country at Chorley Wood, ever continuing busy with the writing of books. Mr. Macnamara married Mia, daughter of the

Hon. Henry Vincent Bayley, and had two sons and six daughters. His eldest son, Lieutenant-Colonel Carroll Macnamara, was killed at the Battle of the Somme.

LEONARD GEORGE GUTHRIE, M.D., B.CH. OXON.,
F.R.C.P. LOND.,

PHYSICIAN, HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE, ETC.

THE death of Dr. Leonard Guthrie, which occurred on the morning of Dec. 24th last as the result of an accident the previous evening, is an event which will bring deep sorrow to many hearts. He was a man of an exceedingly fine sensitive nature, with many friends and no enemies, and he will be mourned alike by gentle and simple. He had reached his sixty-first year, but he had no appearance of such age, and his interest in his work and his recreations was undimmed, and, indeed, had become keener as he advanced in years. He was unmarried, but he lived with a brother to whom he was devoted, and to whom all who know him will offer their keenest sympathy.

Leonard Guthrie was educated at King's College School and then proceeded to Magdalen College, Oxford, where he subsequently took his M.A. and M.D. degrees. His medical education he completed at St. Bartholomew's Hospital. His time there was not very congenial. The energetic and perhaps somewhat boisterous medical student life was not suited to his gentle and retiring nature, and it was only a few years later that he really found his *métier* in clinical work, which he could pursue in his own fashion. He became connected with the Paddington Green Children's Hospital, first as house physician and then as physician, and at the time of his death he was senior physician to that institution. His work there was a constant pleasure to him, and no one will ever know the innumerable acts of unostentatious kindness which he showed to patients and staff alike. He was for several years physician to the North-West London Hospital, but he severed his connexion with that hospital when it became amalgamated with the Hampstead Hospital. He was also on the staff of the Hospital for Epilepsy and Paralysis when it was in Regent's Park, and he remained connected with it when it moved to Maida Vale, and had much to do with its reconstruction there. He became senior physician there on the recent death of his colleague Dr. George Ogilvie, whose career is also made the subject of notice this week. He also acted as consultant to several other institutions, and during the war he was on the staff of Lord Knutsford's Hospitals for Neurasthenic Officers. He had filled the office of President of the Harveian Society and of the Section for the Study of Disease in Children of the Royal Society of Medicine. He had recently been assisting the Registrar of the Royal College of Physicians of London—a duty which gave him the keenest pleasure. His historical knowledge and interests were such as to make such work as he was called upon to do in this capacity extremely congenial, and there is no doubt that the recognition of his ability and capacity which the invitation to such labours implied was a great gratification to one who, like Guthrie, was too modest and too ready to undervalue his own abilities. He had only just been appointed examiner in medicine to the University of Oxford and was keenly anticipating a renewal of his connexion with the University.

Dr. Guthrie's medical interests, as will be evident from his appointments, were chiefly in children's diseases and nervous disorders. His main literary work, "The Functional Nervous Disorders of Childhood," indicated this duality of interests. It is a work of great ability inspired by sympathy and keen observation, and written with a graceful literary charm not too common in medical writings. He also contributed several articles to Garrod and Batten's "Diseases of Children" and to Allbutt's "System of Medicine." His article on "Night Terrors" in that System is one of the best known, and one of the most readable medical articles that has ever been written. His FitzPatrick lectures at the Royal College of Physicians of London on the History of Medicine form a marvellous storehouse of medical history, and it is to be regretted that they were never published in book form. Like many others, he was deeply interested in the medical history of Napoleon Bonaparte, and his article contributed to the International Medical Congress of 1913, "Did Napoleon Bonaparte Suffer from Hypo-pituitarism

Towards the Close of His Life?" is a careful examination of the question, arriving, we feel, at convincing conclusions.

A good many years ago several series of "Hospital Sketches" were published in the *Pall Mall Gazette*, and subsequently appeared as a small volume. It is now known that Leonard Guthrie was the author of these, and all who have read them agree that no such true and accurate, and at the same time humorous, descriptions of out-patient experience at a children's hospital have ever been written. It may well be said that all that Guthrie wrote was characterised by accurate and graphic observation, and was pervaded by scholarliness and human interest. The man was behind all that he wrote, but the man was much more than anything he wrote. His was one of the most delightful and lovable natures, full of sympathy which overflowed in every direction. And yet he was so modest and unassuming that he was almost ashamed to be discovered in any good action. To his friends who all loved him, his loss is irreparable; to those who were nearest and dearest to him his death is no less than a calamity.

GEORGE OGILVIE, M.B., C.M., B.Sc. EDIN.,
F.R.C.P. LOND.,

SENIOR PHYSICIAN TO THE FRENCH HOSPITAL AND TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE; PHYSICIAN, SPANISH EMBASSY.

Dr. George Ogilvie, who died on Saturday, Dec. 14th, 1918, after an illness of some weeks' duration following an accident, was born in 1852. He was educated at Hamilton and at Edinburgh University, where he graduated B.Sc. in Mathematical Sciences in 1875 and M.B., C.M. in the following year. He was also "Neill-Arnett" prizeman. After completing his medical education by taking courses at Paris, Würzburg, Vienna, and Florence, he started practice

as a physician in London. In 1881 he was appointed physician to the Hospital for Epilepsy and Paralysis, Maida Vale, and in 1889 to the French Hospital. He was senior physician to both these institutions at the time of his death, and it was in recognition of his services to the French Hospital that he received the Order of Chevalier de la Légion d'Honneur. For similar services he was created Knight, Order of Isabel la Católica, and Knight, Order of Nossa Senhora de Vila Viçosa by the Spanish and Portuguese Governments respectively. In 1889 he became a Member of the Royal College of Physicians, and in 1908 he was elected to the Fellowship.

As a physician and neurologist he was sound, acute in observation, and essentially practical in treatment. Perhaps the most important of his contributions to medical literature was a paper on the Exceptions to Colles's Law (Med. Chir.

Trans., vol. lxxix.). Although the discovery of the *Spirochaeta pallida* and of the Wassermann reaction renders Colles's law a matter of rather academic interest now, the paper aroused considerable attention and discussion at the time. Other papers of his on the Inheritance of Disease, Les Descendants des Tuberculeux, Hérédité-prédisposition, the Transmission of Syphilis to the Third Generation, show the trend of his studies and investigations, and all are characterised by the same clearness of thought, logical sequence of ideas and conclusions, and, moreover, by punctilious attention to literary style and composition. He was a very well-read man, an ardent student of Shakespeare, poetry, and general literature. An accurate knowledge of the history of individuals and of countries was thus acquired, while he had a curious topographical sense, being able to point out at once on the map the name of any town or locality in the world, however obscure and insignificant it might be. An accomplished linguist, he spoke German fluently and French like a Frenchman, and he had also a sound acquaintance with Spanish and Italian. His reputation as a raconteur was early established, and in pre-war days the entertainment at medical banquets and functions never seemed complete without "some of Ogilvie's stories," which, in his deep grave voice, he told so effectively and humorously. A thoroughly kind-hearted man, he never said an ill-natured word and was ever ready to give help to any struggling or youthful professional brethren. We have sketched a "citizen of the world," and such, with his *bonhomie* and unaffected geniality, strong views, and fairness in argument, was Ogilvie. His imposing presence seemed sometimes to embarrass him, for he often made jocose remarks concerning it, but he was not unduly sensitive on the point, and he thoroughly enjoyed a not altogether flattering presentment of him in the pages of *Punch*.

Death has removed a familiar personage in medical circles, one who was liked by all who knew him, and loved by many friends. He married in 1893 Helen, daughter of the late Surgeon-General John Houston, who survives him, and to whom and other members of his family we tender our sympathy and regret.

C. S. HAWES, M.R.C.S. ENG.

Colin Sadler Hawes, M.R.C.S. Eng., who died after a long illness on Dec. 15th, in his forty-third year, was educated at Haileybury and St. Bartholomew's Hospital, where he was *proxime accessit* for the Brackenbury scholarship and house surgeon. Qualifying in 1900, he went out two years later to South Africa to take up an appointment at the hospital at Grahamstown. It was here that pulmonary tuberculosis became manifest, and the rest of his life was spent in a brave and patient struggle against his disability. For a time he acted as assistant at the sanatorium at Nordrach-upon-Mendip, and after the outbreak of war successively held appointments at St. Andrew's Hospital, Dollis Hill, and at the South African Hospital in Richmond Park. A man with a genius for making friends, and who, given health and strength, would have made a mark in his profession, he has left an example of a struggle against heavy odds borne with fortitude.

Sir William Bartlett Dalby, consulting aural surgeon to St. George's Hospital, died on Dec. 29th last, at Montagu-place, London, where he had resided since his retirement.

Sir Ernest Tritton, the well-known financier, who died on Dec. 28th last, after a short illness, was vice-chairman of the Metropolitan Hospital Sunday Fund.

HOME FOR MEN DISABLED BY THE WAR.—The Committee of the Royal Portsmouth Hospital have become responsible for the management of a large house at Purbrook Park, which under a scheme of the War Pensions Committee is to be fitted up as a home for paraplegics and convalescent discharged sailors and soldiers. It is hoped that accommodation will be available before the end of the present winter for 20 paraplegic cases and from 10 to 15 convalescent cases. The number of Portsmouth men needing treatment increases considerably. There are now no fewer than 4365 disabled men upon the local register.

Correspondence.

"Audi alteram partem."

THE PRACTICE OF THE ABSENTEE.

To the Editor of THE LANCET.

SIR,—The letter appearing under the above heading in your issue of Dec. 28th, 1918, shows that notwithstanding the fairly wide distribution of information and the letter written by Sir A. Pearce Gould after Sir Watson Cheyne's suggestion appeared, the objects and the existence of the "War Emergency Fund" do not seem to be sufficiently known. I beg leave, as treasurer of this Fund, to say that it exists to provide as a free gift assistance to members of our profession who have suffered financially owing to war service. There is no question of loan. There is an impression among some that the fact of having received help would become known in their neighbourhood. Let me say that the means taken to prevent this render such an occurrence practically impossible. The facts are known to a small committee in the first instance—often only the president, secretary, and treasurer. Thenceforward the applicant is represented by a number. Any information can be obtained from the honorary secretary, 11, Chandos-street, Cavendish-square, W. 1. We are prepared to consider applications at any time, and hope no one will look upon this effort on the part of their brethren as a charity. It is a recognition of the sacrifices they have made in many ways, and we hope will be accepted in this spirit and in no sense as a charity.

I am, Sir, yours faithfully,

CHARTERS J. SYMONDS,
Treasurer, War Emergency Fund.

Dec. 31st, 1918.

To the Editor of THE LANCET.

SIR,—For some time past you have been publishing, at intervals, letters written in a similar strain to that of "Major, R.A.M.C. (T.O.)," appearing in THE LANCET of Dec. 28th, 1918. Here are a few choice extracts from his letter: "Sir Watson Cheyne's proposal to lend money to medical men whose practices have been filched from them owing to their absence at the front"; "These men have been as much injured by their professional brethren as their Belgian colleagues have been by the Hun"; and "It is now suggested by Sir Watson Cheyne that some of the ill-gotten gains of the medical pilferers should be advanced on loan at interest to their victims."

This is nice sort of language to use of the medical men who have stayed at home and have overworked themselves in looking after the patients of absentee doctors as well as their own. I honestly believe that in the town to which I belong the medical men who have stayed at home have loyally done their best to play the game and keep together the practices of their absentee colleagues. It has, of course, been impossible to keep the incomes from the absentees' practices up to their former level, for no patient will send as readily for a stranger as he would for his own doctor, and therefore he has probably "carried on" on several occasions when, had his own doctor been at home, he would have sent for him. I am sorry to think it is true that many have suffered as "Major" appears to have done, but that is no justification for alluding to the home profession generally as "medical pilferers." It would be more fair to the men at home if "Major," or any other correspondent wishing to write in the same strain, would sign his letter with his own name, or give the town to which he belongs, or both. Then perhaps something might be done. Many, besides myself, resent extremely the tone of such letters as "Major's," and would have expressed their resentment before, but that they have had something else to do than write letters.

I am, Sir, yours faithfully,

Bolton, Dec. 25th, 1918.

F. R. MALETT.

PRIMITIVE AGENTS IN TREATMENT.

To the Editor of THE LANCET.

SIR,—I was much interested in the leading article which appeared under the above title in your issue of Dec. 21st. I wish heartily to endorse the opinions expressed, since from careful observation and personal direction of these primitive agents I know that they are infinitely more

effective and less costly than other and more generally accepted methods for the remedy of certain disabilities, when intelligently applied. It is in the hope that serious consideration will be given by the State to the adoption of these means not merely for sailors and soldiers disabled in this war but for those engaged in other public or national services of the future that I write this note. At a very large command dépôt, of which I was appointed to the medical charge, I found, on taking over, a great amount of indoor treatment being done with not very satisfactory results, but on sweeping out much apparatus and substituting outdoor physical training a striking improvement followed. The system of open-air physical training was therefore developed to its fullest extent, supplemented by hydro-therapy and massage for a small percentage of cases. Dr. Frank Radcliffe, who contributed a letter to THE LANCET on the Value of Physical Treatment,¹ ably assisted me in this work and had charge of those men requiring special or individual attention. The vast majority of the men were dealt with in larger squads or classes under special instructors who had been trained at the Army Physical Training Schools at Winchester or Aldershot. Graduated exercise has done an immense deal for tuberculosis (the question of auto-inoculation apart), and I am confident that, properly supervised, outdoor physical exercise will refit a large number of men who, treated under other conditions, would drift into a state of pauperism.

I am, Sir, yours faithfully,

J. H. P. GRAHAM,

Manchester, Dec. 23rd, 1918. Lieutenant-Colonel, R.A.M.C. (S.R.).

THE MEDICAL EXAMINATION OF AVIATION CANDIDATES.

To the Editor of THE LANCET.

SIR,—In your issue of Dec. 14th Dr. G. A. Sutherland rightly says that a proper selection of men fit to fly cannot be made unless the examiner is also fit to make a proper selection. He then goes on to show how the examiner should be trained in this work, laying down principles which should act as a guide. With these excellent principles all will agree; the practical application of them, however, on the part of the examiner is by no means easy. It takes time to make an experienced assessor, able to weigh one set of functions against another. The beginner is apt to be over-cautious in estimating the character of the pulse and in imagining cardio-vascular debility. In certain men with large muscles it is difficult to feel the radial pulse when the arm is raised, and it is necessary to press deeply with the fingers. When raising the arm to estimate the character of the pulse the elbow must be bent to prevent the muscles becoming tense. These are some of the practical points liable to be overlooked by beginners.

Standards of aerial fitness must be adapted to the varying conditions. At the beginning of the war it was thought wonderful for an aeroplane to travel 60 miles an hour and to rise to a height of 10,000 feet in half an hour. Now it is usual for airmen to travel at three times that speed and to ascend in one-sixth the time, and the end is not yet. Now, when we subject the human body to such sudden changes in oxygen pressure and temperature it is reasonable to devise some test to decide whether a rapid ascent to a high altitude can be tolerated. This is a question where physiology can be usefully combined with clinical medicine. If a simple test can be devised it should certainly be used. Amongst the borderland cases we want evidence which will throw light on the functional efficiency of the cardio-vascular and nervous systems. Dr. Sutherland suggests that to stand the candidate on one leg with his eyes shut for 15 seconds, to observe whether his outstretched fingers are tremulous and whether his knee-jerks are normal is sufficient evidence for the examiner to go upon. These are all important points, no doubt, but why not test also the cardio-respiratory centres in the medulla? This can be done thus:—

The candidate is directed to expire so as to empty the chest and then to take a deep inspiration and blow through a tube so as to raise a column of mercury to the height of 40 mm. and keep it there for 40 or 50 seconds. The experiment may produce considerable embarrassment, with marked flushing of the face, and when asked to describe his sensations the candidate will often say that he felt a "bursting in the head" or that "he felt giddy." This may be termed an abnormal answer.

¹ THE LANCET, 1918, II., 880.

On the other hand, a youth who has good nervous control and a good cardio-vascular system will hold his breath against 40 mm. Hg pressure, with little or no discomfort for the same period, and his answer will be that he "wanted to breathe" or he "wanted more air"—a normal answer. During the holding of the breath the pulse-rate in the two cases varies: in the normal boy the rate will increase from 20-30 beats per minute and stay there until the end of the experiment, whilst in the abnormal case the rate will increase by 60 or more beats per minute, and before the end of the experiment it will drop to a rate lower than at the commencement. I have watched the manometer test in a great variety of cases, and I feel sure that it has its value and should form part of our examination, because it affords evidence of the stability of nerve centres which cannot be elicited in any other way; but, of course, it should never take the place of a thorough physical examination.

The Medical Research Committee have published some statistics on this subject which show that successful pilots who are fit can pass this test, whilst those who are "stale" or who have suffered from crashes cannot. More work is, no doubt, required before the test can be generally accepted, but at this early stage in the problems of flight we must try to keep our minds open with regard to the tests for flying men.

A number of chamber experiments have been carried out on men who have suffered from faintness or other flying disabilities at certain heights. The conditions prevailing at these varying heights, such as pressure and lack of oxygen, have been reproduced, and it is remarkable how the same symptoms appear again at approximately the same heights. These results seem to me to be too suggestive to be passed over in silence.—I am, Sir, yours faithfully,

H. RONALD CARTER,

Temp. Capt. R.A.F.; late Member, Aviation Candidates Medical Board.
Dec. 17th, 1918.

ADVANCES IN THE TREATMENT OF FRACTURES.

To the Editor of THE LANCET.

SIR,—In their letters in THE LANCET of Dec. 14th and 21st Dr. R. Scott Skirving and Sir W. Arbuthnot Lane have brought to notice again the great importance of Major M. Sinclair's work on the treatment of fractures. The military surgeon has found the methods he has advocated of the greatest value, and a large sum of money in pensions has been saved by their adoption. No other method of splinting can compare with Major Sinclair's for immobilising the parts, extending fractures, and at the same time allowing of easy access for dressing the wound. On his net frame cases that would be otherwise a perfect nightmare to sisters become quite easy to dress and nurse, and the patient ceases to live in constant dread of the next dressing, or drawing of his sheet. By fitting the patient's boot on to a Thomas's splint a cheap and easily obtained ambulatory splint is produced which allows the limb to be used and greatly improves its nutrition. One can scarcely enter any ward without seeing some patients being treated by one or other of Major Sinclair's original methods of extension.

We are, Sir, yours faithfully,

JAMES TAYLOR, Major, R.A.M.C.,
District Consulting Surgeon, Aldershot Command;
W. S. EDMOND, Major, R.A.M.C.,

Dec. 23rd, 1918. Surgeon in Charge, Cambridge Hospital.

THE CAUSES AND INCIDENCE OF DENTAL CARIES.

To the Editor of THE LANCET.

SIR,—For upwards of 20 years I have on several occasions insisted that the appalling prevalence of dental caries and "adenoids" in this country is due to remedial dietetic causes. It was therefore with great interest that I read Major W. E. Nickolls Dunn's letter in your issue of Dec. 21st, calling attention to this matter. I have again and again referred to the prosaic fact that there are among the inhabitants of this country some 200 million carious teeth, as many alveolar abscesses (pyorrhoea alveolaris), and some 30 million root abscesses—for the most part preventable by the simplest possible means. Well may Major Dunn exclaim that it "is impossible to exaggerate the state of the teeth in this country." It constitutes, indeed, a national disgrace. Dr. Sim Wallace has time after time debated this matter with me, and we have long felt that the remedy can only come through the medical profession.

Three great problems confront the Ministry of Health—the problems of food, housing, and venereal diseases—all, I believe, capable of solution by the application of common

sense principles. Serious as are the two latter problems, I place the food problem first, convinced, as I am, that it is the most urgent, and that more preventable disease is due to faulty eating and drinking than to any other cause.

I am, Sir, yours faithfully,

Cavendish-square, W., Dec. 22nd, 1918. HARRY CAMPBELL.

To the Editor of THE LANCET.

SIR,—Like your correspondent Major Nickolls Dunn (THE LANCET, Dec. 21st), I have come to the conclusion that Dr. Sim Wallace's main contentions are demonstrably true, and that the three articles mentioned by Major Dunn are the main offenders in the production of dental caries. With the relaxation of the stringency in food that will come about within the next few months old habits of diet will be returned to, therefore now is the time to act.

The association of which I am acting chairman is attempting by means of lectures and publications to bring the facts before the public, but until the medical profession and the Government act little progress can be made against the habits of a generation. The age at which solid food should be given, its character, when flesh food should be added, and when it should be given in pieces for mastication are instances in which medical practice differs widely. Can it be doubted that the formation of the jaws and the position and caries-resisting power of the teeth are affected by such matters? And there are many reasons for believing that adenoids and enlarged tonsils are due to food factors.

I am, Sir, yours faithfully,

H. BECKETT OVERY, M.D., F.R.C.S.,
Acting Chairman, National Food Reform Association.
Dec. 31st, 1918.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.

To the Editor of THE LANCET.

SIR,—The Medical Officers of Schools Association, which has been established for 34 years, is now desirous of compiling a register of all medical men and women whose professional services are in any way employed in connexion with the hygienic care of schools or colleges. The association would be greatly aided if such members of the profession would forward a postcard with their name, residence, and status in relation to school hygiene on it to the honorary secretaries at 11, Chandos-street, Cavendish-square, W. 1. They would also be obliged if their correspondents would add the names of any professional neighbours so engaged, but at present absent on public service.

I am, Sir, yours faithfully,

G. CHAIKIN,
Hon. Secretary.
Dec. 30th, 1918.

THE SERVICES.

ARMY MEDICAL SERVICE.

Temp. Col. O. Richards relinquishes his commission.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. L. A. Mitchell is placed temporarily on the half-pay list. Capt. W. P. MacArthur to be acting Lieutenant-Colonel whilst specially employed.

Capt. G. G. Collett relinquishes the acting rank of Lieutenant-Colonel and reverts to the acting rank of Major.

Temp. Major P. Hamill (Captain, R.A.M.C., T.F.), relinquishes his temporary commission on re-posting.

Temp. Capt. A. G. MacLeod, C.A.M.C., to be acting Major while employed as S.M.O.

Temporary Lieutenants to be temporary Captains: B. W. Skinner, D. McCormack, A. S. Moorhead, R. F. Buckler.

Temporary honorary Lieutenants to be temporary honorary Captains: O. H. Stansfield, M. Bronk.

Officers relinquishing their commissions: Temp. Majors W. D. Anderson, R. Dick; Temp. Capt. F. L. Underwood, G. D. Laing, J. Howe, J. L. Digby, G. B. Lindsay, B. W. Cohen, W. F. H. Ives, J. L. Falconer, M. A. Spotswood, S. Robson, P. P. Warren, E. L. Matthew, E. B. T. Nuthall, R. Wilson, W. L. Dibb, W. G. L. Wambeck, C. T. M. Flwright, T. Duncan, H. W. Barber, J. B. C. Brockwell, E. A. Peters, and E. O'D. Graham and V. T. W. Eagles (on account of ill-health contracted on active service, and retain the rank of Captain); Temp. hon. Capt. S. A. Henry (on ceasing to be employed with St. John Ambulance Brigade Hospital); S. Alexander, A. G. Harvey, F. W. Lyle, A. Chance, F. B. Julian, T. J. Ryan, J. A. Wood, J. O. Osburne, C. W. B. Littlejohn, S. N. Babington, I. M. Swanepoel, J. C. Watt, W. Mackenzie, H. S. Turner, J. Ellenbogen, C. O. Stallybrass, A. F. G. Kerr; Temp. Lieuts. A. N. Symons, N. J. McCaskie, C. P. Lankester, G. F. N. Taylor, A. J. Watt, J. B. Minford, J. Morton, E. W. Whiting, B. Magoveny, H. J. Villiers, A. G. Heron, A. W. H. Cheyne.

Canadian Army Medical Corps.

Temp. Lieut.-Col. W. H. Delaney to be temporary Colonel. Temporary Captains to be acting Majors: R. M. Fergusson, while employed at a Stationary Hospital; C. E. Preston, while employed as Surgeon, No. 15 Canadian General Hospital, Taplow; F. W. Blake-man, whilst employed at No. 5 Canadian General Hospital.

Canadian Army Dental Corps.

Temp. Lieut. C. C. Graham to be temporary Captain.

SPECIAL RESERVE OF OFFICERS.

Lieutenants to be Captains: N. H. S. Maelzer, W. H. Rowden, J. Thompson, G. B. Birkett, G. R. Sharp, F. L. Richard, C. H. Warner, F. Cameron, A. Wingfield, J. L. D. Buxton, E. P. N. Creagh, J. A. Stewart, T. P. Lloyd.

Cpts. D. Laughlin and E. R. Chambers relinquish their commissions on account of ill-health contracted on active service and retain the rank of Captain.

To be Lieutenants: W. E. P. Briggs (from Manchester University Contingent, O.T.C.), G. Winter.

TERRITORIAL FORCE.

Capt. (acting Major) T. H. Richmond to be acting Lieutenant-Colonel whilst specially employed.

The undermentioned are seconded for service with the R.A.F.: Majors W. G. Mitchell, A. H. Hogarth; Cpts. W. H. Bennett, D. Cameron, J. H. Chauncy, J. P. N. Casey, C. O. Fitzgerald, O. Gleeson, J. J. C. Hamilton, J. M. Kirkness, F. C. Kempson, Andrew MacLennan, J. A. Parsons, F. Roberts, A. Scott-Turner, F. J. P. Saunders, H. J. Shanley, E. M. S. Turner, N. R. Williamson, C. Webb, A. Sutcliffe.

5th London General Hospital: Capt. J. M. Wyatt is seconded for service with the R.A.F.

1st London Sanitary Company: Capt. E. W. Gregory is seconded for service with the R.A.F. Lieut. A. G. Harrington to be Captain and to remain seconded.

TERRITORIAL FORCE RESERVE.

Major W. B. Armstrong, from Attached to Units other than Medical Units, to be Major.

Capt. (Bt. Major) W. J. Wilson, from List of Officers Supernumerary for Service with O.T.C., to be Captain.

Cpts. D. Davidson and T. Higson, from Attached to Units other than Medical Units, to be Captains.

Cpts. R. Hitchings and A. T. Swan, from the General List, to be Captains.

Capt. (acting Major) F. Wigglesworth, from 1st West Riding Field Ambulance, to be Captain.

Cpts. W. J. Phillips and G. Chandler, from Attached to Units other than Medical Units, to be Captains.

Lieut.-Col. J. S. Warrack, from Home Counties Casualty Clearing Station, to be Lieutenant-Colonel.

Capt. (acting Major) W. Brander, from 3rd East Anglian Field Ambulance, to be Captain.

Capt. (acting Major) S. J. Clegg, from Northern Division Sanitary Section, to be Captain.

Capt. (acting Major) W. H. Davison, from South Midland Division Sanitary Section, to be Captain.

Capt. (acting Major) N. M. Fergusson, from Attached to Units other than Medical Units, to be Captain.

Capt. I. C. Keir, from 1st South-Western Mounted Brigade Field Ambulance, to be Captain.

Capt. J. J. S. Lucas, from 2nd Southern General Hospital, to be Captain.

Capt. E. Hulme, from 2nd East Lancashire Field Ambulance, to be Captain.

Capt. W. C. F. Harland, from attached to Units other than Medical Units, to be Captain.

Capt. D. M. Johnston, from 1st Home Counties Field Ambulance, to be Captain.

Capt. W. Smith, from 2nd Northumberland Field Ambulance, to be Captain.

Capt. (acting Lieut.-Col.) G. C. E. Simpson, from West Lancashire Casualty Clearing Station, to be Captain.

Capt. D. S. Sutherland, from 1st London Field Ambulance, to be Captain.

ROYAL AIR FORCE.

Medical Branch.—The undermentioned are granted temporary commissions:—As Captains: G. Sparrow (temp. Surg., R.N.), C. C. O'Malley (temp. Surg., R.N.). As Lieutenants: W. J. S. Cameron.

Dental Branch.—L. C. W. Balls is granted a temporary commission as Lieutenant.

DONATIONS AND BEQUESTS.—By the will of the late Lord Rhonda, Gonville and Caius College, Cambridge, and King Edward VII. Hospital, Cardiff, will each receive £20,000.

IN THE ORDER OF THE INDIAN EMPIRE. Lieutenant-Colonel John Telfer Calvert, I.M.S., principal of the Medical College of Calcutta; Major John Hanna Murray, I.M.S.; Lieutenant-Colonel F. E. Swinton, I.M.S., medical store-keeper, Bombay; and Lieutenant-Colonel J. C. Lamont, I.M.S. (ret.), professor of anatomy, Medical College, Lahore, India, receive Companionships. Mr. J. D. Price, officiating civil surgeon at Nowgong, Assam, has received the Kaiser-i-Hind Medal of the First Class.

THE ADVISORY COMMITTEE ON T.N.T. POISONING.—The Advisory Committee on T.N.T. Poisoning have asked the Minister of Munitions to express to Dr. J. B. G. Skelton, of the Welfare and Health Section of the Ministry, their gratitude for the valuable work which has been carried out amongst the workers in the T.N.T. factories. The Minister of Munitions states that the success which has followed material dependence on the medical profession has been mainly due to Dr. Skelton's unselfish and loyal service.

THE LANCET, VOL. II., 1918: THE INDEX.

THE Index and Title-page to the volume of THE LANCET which was completed with the issue of Dec. 28th, 1918, is in preparation. Owing to the continued shortage in the paper-supply, the Index will not be issued with all copies of THE LANCET, as was the custom prior to the War. Subscribers who bind up their numbers are requested to send a post-card (which is more convenient for filing purposes than a letter) to the Manager, THE LANCET Office, 423, Strand, London, W.C. 2, when a copy of the Index and Title-page will be supplied free of charge.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—T. A. Jordan (Sects. I. and II.), Manchester; J. E. Nicole (Sects. I. and II.), Westminster Hosp.; S. H. Robinson (Sect. I.), Guy's Hosp.; G. E. Spero (Sect. II.), London Hosp.; and C. de B. Thomson (Sect. I.), Middlesex Hosp.

Medicine.—T. A. Jordan (Sect. II.), Manchester; F. W. Kemp (Sect. II.), Charing Cross Hosp.; and J. E. Nicole (Sect. II.), Westminster Hosp.

Forensic Medicine.—W. S. Hughes, Charing Cross Hosp.; J. Kershaw, Manchester; and S. Robinson, St. Thomas's Hosp.

Midwifery.—J. Kershaw, Manchester.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: T. A. Jordan, J. E. Nicole, and S. Robinson.

UNIVERSITY OF DUBLIN, TRINITY COLLEGE, SCHOOL OF PHYSIC.—At examinations held recently the following candidates were successful:—

FINAL MEDICAL EXAMINATION.

Part I., Materia Medica and Therapeutics, Jurisprudence and Hygiene, Pathology.—Leonard Abrahamson, Robert Dormer, Salmon Louis Feldman, William Bernard Joseph Pemberton, Maurice Nurock, Johannes Martinus Benjamin de Wet, Wouter De Vos Scholtz, Johannes Philippus de Villiers, Doris Louisa Graham, Joseph Ballantyne Maguire, and Elsie Anna Burns.

Materia Medica and Therapeutics, Jurisprudence and Hygiene only.—Percival Israel Levitt.

Pathology (in completion).—Gerald FitzMaurice Keatings and Samuel Reginald Hill.

Part II., Medicine (M.B.).—William Philip Biford, Thomas Mulock-Bentley, Robert Bevan Nangle Smartt, Herbert Stratford Collins, William Alfred Shannon, Becher FitzJames Haythornthwaite, Cecil Joseph Quinlan, James Edward Jameson, Frederick John Dymoke, Ethel Marjorie Luce, and Johannes Tobias Mynhardt.

Surgery (B.Ch.).—John Henry Coolican, William Philip Biford, William Sweetman, Louis John Patrick Murphy, William Alfred Shannon, Alewyn Johannes Vorster, Eric Reginald Tivy, Kenneth MacGregor Greer, Ethel Marjorie Luce, and Eric James Lyndon.

Midwifery (B.A.O.).—Victor Millington Syngé, Henry Blundell Van der Merwe, Gertrude Rice, John Charles Joseph Callanan, Alfred Leopold Wilson, Johannes Tobias Mynhardt, Albert Hugh Thompson, Louis John Patrick Murphy, William Joseph Hogan, Richard William Shaw, William Andrew Byrn, James Sinclair Quin, Gerald FitzMaurice Keatings, Samuel John Laverty, Thomas James Russell Warren, and Cecil Joseph Quinlan.

DIPLOMA IN PUBLIC HEALTH.

Part I., Bacteriology, Pathology, Chemistry, Physics, and Meteorology.—John Speares, Alexander Hugh Blaxell Pearce, Joseph Warwick Bigger, and Harold Sanderson Sugars.

Part II., Sanitary Engineering, Vital Statistics and Public Health, Hygiene, and Epidemiology.—Joseph Warwick Bigger, Edgar Ormond Bowie, James Beckett, Alexander Kirkpatrick Cosgrave, and Alexander Hugh Blaxell Pearce.

At the meeting of the Society for the Study of Inebriety, to be held in the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., on Tuesday, Jan. 14th, at 4 P.M., Lord d'Abernon will deliver an address on the Scientific Basis of Drink Control.

NEW REGULATIONS FOR THE SUPPLY OF CREAM.

With a view to relieving in some measure the present shortage of milk, the Food Controller has issued a new Order, the Cream Order, 1918, which places further restrictions on the supply of cream. The Order will come into force on Monday next, Jan. 6th, and will further restrict the sale of cream. Cream for children under 5 will be limited to a maximum of half a pint per week. To obtain cream for such children applications should be made to the local Food Committee for a permit, which should be lodged with the retailer. In the case of invalids, permits for cream may be granted as an alternative to butter and margarine. These will be granted by the Food Committee on a medical certificate in the case of invalids suffering from certain specified diseases. Applications in respect of invalids suffering from other diseases must be submitted by the Food Committee for special authorisation from the Medical Section of the

Ministry of Food. Such applications must be accompanied by a medical certificate giving specific reasons why cream is recommended. Directions as to cases in which applications for cream may be entertained by the Food Committees are being furnished to medical practitioners for their guidance. Applications in respect of inmates of institutions must be made by the head of the institution on their behalf, and all existing authorities for cream in the hands of consumers and retailers will cease to be valid and fresh applications will have to be made.

Sir Robert Armstrong-Jones will deliver the Gresham lectures on Physic at Gresham College on Tuesday, Wednesday, Thursday, and Friday, Jan. 14th to 17th, each day at 6 o'clock. On the first day (Tuesday) the subject of the lecture will be "Heredity," with special application to mental and nervous diseases; Wednesday, "Alcohol: its Use and Abuse"; Thursday, "Venereal Diseases: their Consequences and their Control"; Friday, "Influenza and its Results," especially in regard to the measures taken to combat its spread.

METROPOLITAN ASYLUMS BOARD: DIPLOMA IN PUBLIC HEALTH.—A course of lectures and demonstrations in hospital administration, extending over three months, will be given at the Western Hospital, Seagrave-road, Fulham, London, S.W., by Dr. R. M. Bruce, medical superintendent, on Tuesdays and Fridays, at 5 P.M., beginning Tuesday, Jan. 7th. The fee for the course is £33s., payable to the Clerk to the Metropolitan Asylums Board, Embankment, London, E.C. 4.

THE ROYAL INSTITUTE OF PUBLIC HEALTH.—In connexion with the work of the Venereal Diseases Department of the above institute a special conference will be held on Wednesday next, Jan. 8th, at 4 P.M., when Professor J. G. Adami, M.D., F.R.S., Colonel, C.A.M.C., will open a discussion on the Prevention and Arrest of Venereal Disease in the Army. The chair will be taken by Lord Sydenham, and amongst those who will take part in the discussion are: Dr. Mary Scharlieb, Colonel M. A. De Laney, Liaison Officer, U.S. Army; Colonel William F. Snow, M.C., U.S.A.; Lieutenant-Colonel George Walker, M.C., U.S.A.; Colonel Hugh H. Young, Chief of the Division of Urology, American Expeditionary Force; Lieutenant-Colonel L. W. Harrison, D.S.O., medical officer in charge, Rochester Row Military Hospital.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held at Queen Anne's Gate Buildings, Westminster, on Dec. 19th, with Sir Francis H. Champneys in the chair. A midwife was struck off the Roll, the following charges amongst others having been brought forward:—

Neglecting to wash the patient, as required by Rule E.8, at any time after the day of the confinement; neglecting to take and record the pulse and temperature of the patient at each visit, as required by Rule E.14; entering on her records false statements of the pulse and temperature of the patient; neglecting to wash the patient on the termination of the labour, as required by Rule E.9; neglecting to remove the soiled linen, &c., used at the confinement from the neighbourhood of the patient, as required by Rule E.11; and endeavouring to persuade the patient to give to the officers of the local supervising authority false information regarding the number of her visits and her compliance with Rule E.14. That when attending her patients the midwife did not on each occasion wear a clean dress of washable material, as required by Rule E.2, and she neglected to afford to the inspector of midwives of the local supervising authority reasonable facilities for an inspection of her methods of practice, and more particularly she was guilty of obstructing the inspector in carrying out such inspection.

At a meeting held on Dec. 19th a letter was considered from the chairman of the Standing Committee of the County Nursing Associations of the Queen Victoria's Jubilee Institute for Nurses asking the Board to hold more frequent examinations in London. The Board decided that the reply be that the Board is unable to see its way to comply with the request of the Standing Committee of the County Nursing Associations of the Queen Victoria's Jubilee Institute for Nurses.—A letter was considered from Dr. Herbert Williamson, physician-accoucheur, St. Bartholomew's Hospital, with reference to the admission to the Board's examination of a nurse of Danish nationality. The Board directed that Dr. Williamson be informed that, having regard to the Board's resolution on the subject, the Board regrets its inability to make an exception in any particular case.—The Board having considered draft rules requiring a midwife to notify the local supervising authority when she has advised artificial feeding, decided that the rules as amended be approved, subject to the approval of the Privy Council.—The Board having considered draft rules regulating the payment of expenses incurred by members in respect of their attendance at meetings of the Board, decided that the rules as amended be approved, subject to approval by the Privy Council.—The Board having considered draft rules deciding the conditions under which midwives may be suspended from practice in penal cases by (a) the Board, (b) the local supervising authority, decided that the rules be approved, subject to approval by the Privy Council.

Appointments.

Low, V. WARREN, C.B., has been appointed a Member of the Court of Examiners of the Royal College of Surgeons of England.

MARRING, THOMAS DAVIS, M.B., B.S. Lond., L.R.C.P. Lond., M.R.C.S., Medical Officer for the Weymouth District.

The following have been appointed Surgeons under the Factory and Workshop Acts: WADE, N. N., M.D. Edin. (Risca District of Monmouth); HULL, G. E., L.A.H. Dub. (Rogerstone District of Monmouth); ROBERTSON, J. M., M.B., C.M. Glasg. (Biggar District of Lanark); REES, M. W., L.R.C.P. & S. Edin. (Llanfair Caereinion District of Montgomery).

Vacancies.

For further information refer to the advertisement columns.

Aberystwyth Infirmary & Cardiganshire General Hospital.—H.S. £200.

Aylesbury, Bucks County Asylum.—Asst. M.O. £350.

Bedford County Hospital.—H.S.

Birmingham General Dispensary.—Res. M.O. £360.

Bolingbroke Hospital, Wandasworth Common, S.W.—Res. M.O. £200.

Bradford Royal Infirmary.—H.S.

Bristol General Hospital.—Sen. H.S. £300.

Chichester, Royal West Sussex Hospital.—H.S. £180.

Edinburgh, General Diseases Scheme.—Female Asst. M.O. £400.

Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—Female

Obst. Asst. £50.

Exeter City Mental Hospital, Digby, near Exeter.—Asst. M.O. £300.

Glanmorang County Asylum, Bridgend.—Temp. Asst. M.O. £86s. per wk.

Greenock Corporation.—Female Med. Prac. £350.

Guildford, Royal Surrey County Hospital.—H.S. £250.

Heltingly, Sussex, East Sussex County Asylum.—Temp. Asst. M.O.

7 gs. per week.

Hospital for Sick Children, Great Ormond-street, London.—H.S. £100.

Huddersfield County Borough Education Authority.—Asst. School

M.O. £350.

London Homeopathic Hospital, Great Ormond-street and Queen-square,

W.C.—R.M.O. £80.

Manchester, Ancoats Hospital, Mill-street.—Hon. P.

Manchester Royal Infirmary and Dispensary.—Hon. Asst. Gyn. S.

Margate, Royal Sea Bathing Hospital for Surgical Tuberculosis.—S.

£200.

National Hospital for Diseases of the Heart.—Non-Res. M.O.

National Orthopaedic Hospital.—Res. H.S. £100.

Norwich, Norfolk and Norwich Hospital.—H.P. £250.

Plymouth, South Devon and East Cornwall Hospital.—H.S. £250.

Putney Hospital, Lower Common, S.W.—Res. M.O. £150.

Rochdale Infirmary and Dispensary.—Jun. H.S. £100.

Rotherham Hospital.—Sen. H.S. £250.

St. Mark's Hospital, Gray's Inn-road, W.C.—Sen. Res. M.O. £200.

St. Mark's Hospital for Cancer, Fistula, and Other Diseases of the

Rectum, City-road, London, E.C.—H.S. £250.

Shrewsbury County Asylum.—Two Locum Tenentes. 7 gs. per week.

Southampton Free Eye Hospital.—Asst. Oph. Surg. £100.

Westmorland Sanatorium, Meathop, Grange-over-Sands.—Asst. M.O.

£300.

Whitehaven and West Cumberland Infirmary.—Res. H.S. £150 to £180.

Wolverhampton and Staffordshire General Hospital.—Senior Student

as Assistant. Also Res. M.O. £200. Also H.S. £200.

The Chief Inspector of Factories, Home Office, S.W., gives notice of

vacancies for Certifying Surgeons under the Factory and Workshop

Acts at Rochdale, Lancs; and at Shrewsbury, Shropshire.

The Home Secretary gives notice of a vacancy for a Medical Referee

under the Workmen's Compensation Act, 1906, for the Alfreton,

Buxton, Chapel-en-le-Frith and New Mills, and Chesterfield

County Courts in Circuit No. 19. Applications should be addressed

to the Private Secretary, Home Office, London, S.W., not later than

Jan. 15th, 1919.

Births, Marriages, and Deaths.

BIRTHS

HANCE.—On Dec. 23rd, 1918, at Bombay, India, Catherine (née Leonard), the wife of Major J. Bennett Hance, I.M.S., of a daughter.

MARRIAGES

GIBSON—FLETCHER.—On Dec. 28th, 1918, at the Parish Church, Standish, Lancashire, Major Richard E. Gibson, O.B.E., R.A.M.C., to Daphne Margaret, youngest daughter of the late Ven. R. C. Fletcher, Archdeacon of Blackburn, Rector of Chorley.

DEATHS

BENNETT.—On Dec. 28th, 1918, at Paignton, suddenly, Lawrence H. Bennett, M.B. Oxon.

GUTHRIE.—On Dec. 24th, 1918, from injuries received in an accident, Leonard George Guthrie, M.A., D.M. Oxon., F.R.C.P., Upper Berkeley-street, Portman-square, W., in his 61st year.

SHELMERDINE.—On Dec. 28th, 1918, at Torleigh, St. Mary Church, Herbert Shelmerdine, M.B., in his 59th year.

TURNER.—On Dec. 24th, 1918, instantaneously, the result of a lift accident, Douglas Hamilton, younger son of Captain William Turner, R.A.M.C.T. M.S., F.R.C.S., of 92, Harley-street, W.1, aged 8 years 10 months.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.1.

MEETINGS OF SECTIONS.

Thursday, Jan. 9th.

NEUROLOGY (Hon. Secretaries—C. M. Hinds Howell, E. G. Fearnside): at 8.30 P.M.

Papers:

Captain T. A. Ross: Interrelations of Peace and War Neuroses.

Lieut.-Colonel A. F. Hurst and Major Symms: Hysterical Element in Organic Nervous Injuries and Diseases (with cinematographic demonstration).

Friday, Jan. 10th.

EPIDEMIOLOGY AND STATE MEDICINE (Hon. Secretaries—William Butler, M. Greenwood): at 5.30 P.M.

Paper:

Lieut.-Colonel Martin Flack, R.A.F.: Some Simple Tests for Physical Efficiency.

Those Members of the Section who desire to dine after the Meeting are requested to send in their names to Captain Greenwood, 7, Northumberland-street, W.C. 2, not later than Jan. 8th.

The Royal Society of Medicine keeps open house for R.A.M.C. men and M.O.'s of the Dominions and Allies. The principal hospitals in the metropolis admit medical officers to their operations, lectures, &c. Particulars on application to the Secretary at 1, Wimpole-street, London, W.1.

RÖNTGEN SOCIETY, at the Royal Society of Arts, 18, John-street, Strand, W.C.

TUESDAY, Jan. 7th.—8.15 P.M., General Meeting. Paper: Dr. H. S. Allen: Electrical Changes produced by Light.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c. POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

Clinics each week-day at 2 P.M., Wednesday, Friday and Saturday also at 10 A.M.

(Details of Post-Graduate Course were given in issue of Nov. 30th, 1918.)

Communications, Letters, &c., to the Editor have been received from—

A.—Dr. D. E. Anderson, Lond.;

Sir R. Armstrong-Jones, Lond.;

Messrs. Abdulla and Co., Lond.;

Col. J. G. Adami, A.D.M.S.;

Communications relating to editorial business should be addressed exclusively to The Editor of THE LANCET, 423, Strand, London, W.C. 2

Notes, Short Comments, and Answers to Correspondents.

HOSPITALS AND DISPENSARIES IN INDIA, 1917-18.

In the *United Provinces* there was a severe visitation of plague, which in the epidemic year reckoned from July 1st, 1917, to June 30th, 1918, caused 173,881 deaths, nearly double the mortality of the preceding year, and greater than in any year since 1910-11; it reached its maximum in March (41,759 deaths), and then rapidly decreased, the June deaths numbering only 566. Rat destruction gave very satisfactory results, and evacuation of infected villages is increasing in popularity with the inhabitants. Colonel C. Mactaggart, C.I.E., I.M.S., refers to the good work done by the Lucknow Anti-tuberculosis League by means of magic lantern lectures, pictorial posters, and distribution of pamphlets on the subject among the clerical establishments in various offices.

In the report on hospitals and dispensaries in *Burma* Colonel P. C. H. Strickland, I.M.S., refers to the difference in small-pox mortality among vaccinated and unvaccinated persons; 3 out of 126 vaccinated cases were fatal, while out of 71 unvaccinated cases 16 were fatal, the respective percentages being 2.38 and 22.5. Ten dispensaries had to be closed on account of the war.

In the *North-West Frontier Province* a total of 12,650 patients were treated in hospital, showing a decrease of 235 on the preceding year, four dispensaries and two hospitals having been closed, though, on the other hand, three new hospitals have been opened. It is remarked by Lieutenant-Colonel T. W. Irvine, I.M.S., the chief medical officer of the province, that "the total number of in-patients is always disappointing, and has been remarked on repeatedly." Accommodation is provided for 901 patients, but the average daily number under treatment was only 435. Lieutenant-Colonel Irvine considers that this shows that "the public not only doubt the skill of the medical staff, but have other and good reasons for not availing themselves to a much greater degree of this accommodation." Such a statement appears to require explanation.

THE TREATMENT OF SCURVY.

To the Editor of THE LANCET.

SIR,—In your issue of Dec. 21st last Dr. Muir Evans quotes a prescription, published in 1676, for making medicated beer, which includes horse-radish and scurvy-grass. The same use of horse-radish was recommended still earlier by Dr. John Woodall in "The Surgeon's Mate" (published in 1617), where he says that "Horse-radish sauce alone, or mixed with beer, is exceeding good." Dr. Woodall suggests also using herbs, including scurvy-grass and sorrel, in new milk or whey. There is an early tribute to the usefulness of scurvy-grass in the account by Gerrit de Veer of the voyages of Willem Barentz (1594-97).

"There to our great good we went on land, for in that island we found great store of leple leaves (*lepel-bladeren*, spoonwort or scurvy-grass, *Cochlearia officinalis*) which served us exceeding well; and it seemed that God had purposely sent us thither, for as then we had many sick men, and most of us were so troubled with a scouring in our bodies (*schorbok*, scurvy) and were thereby become so weak that we could hardly row, but by means of those leaves we were healed thereof: for that as soon as we had eaten them we were presently eased and healed, whereto we could not choose but wonder, and therefore we gave God great thanks for that and for other his merces showed to us, by his great and unexpected aid lent us in that our dangerous voyage. And so, as I sayd before, we ate them by whole handfuls together, because in Holland we had heard much spoken of their great force; and as then found it to be much more than we expected."

But later Arctic explorers have, I believe, expressed the opinion that sorrel (*Rumex acetosella*) is more effective than scurvy-grass.

I am, Sir, yours faithfully,

Dec. 23rd, 1918.

A. HENDERSON SMITH.

A NASAL DOUCHE.

WE have received from Messrs. Hewlett and Son, Charlotte-street, London, E.C., a neat and convenient form of nasal douche. Its appearance is that of a small bulb-shaped pipette, and it consists of a glass tube about 4 inches long, closed at one end and having at the other end a pear-shaped bulb with an orifice to allow the medicament to escape. The central part of the tube is a bulb into which the medicament is poured through an orifice which also serves as a vent-hole. The closing or unclosing of this hole by the finger controls the flow of the fluid. As the douche is made of toughened glass it can be sterilised by boiling without fear of breakage.

COLONIAL HEALTH REPORTS.

British Guiana.—Mr. G. B. Greene, Assistant Government Secretary, in his report on the Blue-book for 1917, states that the estimated population of the colony on Dec. 31st was 313,999—163,405 males and 150,594 females. The birth- and death-rates per 1000 of the population of the several races representing the community were as follows:—

| Race. | Birth-rate. | Death-rate. | Race. | Birth-rate. | Death-rate. |
|------------------------------------|-------------|-------------|-----------------|-------------|-------------|
| Europeans other than Portuguese... | 9.6 | 13.7 | Chinese ... | 25.6 | 23.5 |
| Portuguese ... | 25.9 | 31.2 | Blacks ... | 27.9 | 29.9 |
| East Indians ... | 27.6 | 33.1 | Mixed races ... | 32.0 | 21.5 |

The number of deaths of children under 1 year of age was 1781, or 199 per 1000 births. The mean rate for the previous five years was 183 per 1000. The six principal causes of death throughout the colony during the past five years are given by the Registrar-General as follows: Bowel complaints (including dysentery, diarrhoea, and enteritis, &c.), 13.4 per cent. of the general mortality; fever (malarial and other), 14.3 per cent.; pneumonia and bronchitis, 12.2 per cent.; kidney diseases, 9.6 per cent.; diseases of early infancy (including premature birth, infantile debility, &c.), 8.9 per cent.; and phthisis and other forms of tuberculosis, 6.3 per cent. Enteric fever is a notifiable disease; during 1917 723 cases were notified, with 123 deaths. Antimalaria and antimosquito measures are being generally and gradually enforced, with visible signs of success. Ankylostomiasis, which has engaged the attention of the medical department for several years, has considerably decreased on the sugar estates; this is attributed to improved sanitary measures and the erection of latrines. The hospitals and asylums of the colony were maintained during the year in their usual efficient condition. There are five public hospitals in the principal centres of population and the outlying districts are served by dispensary hospitals and dispensaries. The immigration law also requires the maintenance of hospitals on every plantation on which there are indentured East Indian labourers, and those institutions are available for the treatment of emergency and pauper cases from the general community. There were 439 patients in the public hospitals at the beginning of the year, and 13,271 were admitted during the year; there were 1413 deaths. In addition to those admitted to hospital outdoor treatment was given to 55,388 persons. At the Leper Asylum there were 297 patients when the year began—205 males and 92 females. During the year 71 were admitted.

Enquirer.—It has been explained in our columns, but we will make an opportunity for repeating the information.

THE price of the book entitled "Married Love," reviewed in THE LANCET of Dec. 28th, 1918, is now 6s.

Burberrys' annual sale takes place as usual in the months of January and February at their Haymarket, London, house, and affords the opportunity to obtain from their surplus stock, at about half the ordinary cost, any of their weatherproof topcoats, suits, and gowns.

At the last meeting of the Taunton town council it was decided to appoint Dr. H. J. Alford consulting medical officer of health and school medical officer at a salary of £350 per annum.

THE LANCET

Is published weekly, price 10d., by post 10½d. inland, and 11½d. colonies and abroad.

A Final Contribution

THE STUDY OF SHELL SHOCK.¹

BEING A CONSIDERATION OF UNSETTLED POINTS
NEEDING INVESTIGATION.

By CHARLES S. MYERS, M.D., Sc.D., F.R.S.,
LIEUTENANT-COLONEL, R.A.M.C. (T.C.).

No medical officers have felt the strain of war more severely than those engaged in the treatment of functional nervous disorders. Both in this country and overseas their time and energies have been so fully occupied that any systematic research in their special sphere of work has been generally out of the question. But now, perhaps, this tension may be relieved; and inasmuch as, even at this late hour, it is still possible to investigate various problems which have arisen during the past four years, I have endeavoured in this paper to draw attention to those which seem to me of the greatest importance. If, perchance, there be any who have relevant data which are too scanty to be published separately and would otherwise lie hidden away in note-books, I shall be happy to receive them, and will, of course, be careful to acknowledge their source in any compilation which can be usefully made from them.

ETIOLOGY.

There is a general agreement that the war neuroses are to be regarded as the result of functional dissociation arising from the loss of the highest controlling mental functions. Yet considerable controversy exists as to how those controlling functions are lost, and precisely what occurs when they are lost. Some, for example, consider that functional nervous disorders are dependent on increased suggestibility arising from fear, horror, or other emotional or fatiguing conditions; while others maintain that, quite apart from suggestion, emotional conflict or excitement is capable of producing functional disorders. Some have distinguished a so-called commotional from an emotional syndrome; others have insisted that whether a man has been buried in a trench or has seen his best friend's brains scattered before him the functional symptoms are identical. All now agree that mere concussion or the poisonous action of carbon monoxide or other noxious gases does not necessarily give rise to functional nervous disturbance.

Many neurologists hold that the effects of suggestion and of functional disturbance are limited to phenomena which can be imitated voluntarily by the patient; they accordingly limit functional disturbances to those which can as well be produced by malingering. Hence local or general sweating, vaso-motor disturbances, changes in the reflexes or in muscular tone, and any disorders of movement which do not disappear during sleep or under an anæsthetic cannot, according to this view, be due to suggestion and cannot be classed as functional disorders.

But cases of contracture occur which clearly cannot be imitated voluntarily; so do, more seldom, cases of spasmodic movement and of incoördination. The persistence of contracture or of spasmodic movement is likewise unimitable by volition. Moreover, every physician of experience must have met with patients suffering from functional deafness, whose sleep has not been in the least disturbed by the loudest noises, and they must have seen contractures and spasmodic movements persisting during sleep and during at least the first stages of chloroform anæsthesia. We may recall the case of persistent contracture described by G. Ballet,² which was carefully tested during sleep by means of stamp-paper gummed to the affected region.

It has, however, been objected that in such exceptional cases of contracture the possibility of joint adhesions has not been considered, or that the contractures are due to peripheral causes and are therefore to be placed in a special group of "reflex contractures." In this country, at least, I think it difficult to exaggerate the harm that has arisen

from an uncritical acceptance of Babinski's hypothesis of "reflex" paralysis or contracture. I have met with expert neurologists who, on diagnosing a case as belonging to the "reflex" group, have at once regarded it as "organic" and have refused it admission to one of the special hospitals for functional disorders. For my part, I have never seen such a case in which the paralysis or contracture has not been cured by psycho-therapeutic measures (aided, sometimes, by manipulation under an anæsthetic), and the other so-called reflex symptoms (loss of muscular tone, coldness, sweating, &c.) have not disappeared *pari passu* with the regain of normal voluntary movement.

Chief Topics for Investigation.

There are, then, three main topics for investigation: (1) the existence of distinct commotional and emotional syndromes; (2) the justification for limiting the effects of suggestion to volitionally imitable phenomena; (3) the sufficiency of suggestion as an explanation of all functional dissociation.

Of these the first merely requires the collection of observations. My own experience is that in patients who have been exposed to physical violence (i.e., having been buried, knocked over, or lifted in the air), stupor, hyperæsthesia, and spasmodic movements are commoner than in those whose disorder has a purely mental origin. If these differences are confirmed by others their explanation would not be difficult, but at the present moment would be out of place. So, too, it would be inopportune here to consider whether a special kind of commotion—e.g., a fine "molecular" commotion, such as might be produced by moderately short waves of the disturbed air—may ever be directly responsible for functional disorder, producing dissociation through its exhaustive effect on the higher "intellectual" regions or through its excessively stimulant effect on the lower "emotional" regions. In passing, we may note that emotion alone can give rise to increase of pressure and of albumin content, and even, according to some, to leucocytosis in the cerebro-spinal fluid. But fuller observations are needed on this matter.

The second topic suggests a variety of investigations. Can suggestion produce local pallor or blushing? Most experts in hypnosis maintain that local disturbances in blood-supply can be induced by hypnotic suggestion. Some claim even to have produced blisters, but further work under the careful conditions adopted by Captain J. A. Hadfield, R.A.M.C. (then a naval surgeon³) is urgently needed. Similarly in regard to local sweating, &c.

The third topic involves the consideration of the other causes, besides suggestion, which have been advanced as responsible for functional dissociation. Some have thought that an excessive emotional experience may suffice to bring it about. Others have laid stress on the repression of an emotion or instinctive action arising from its conflict with other antagonistic processes, especially with the higher motives of conscience, social sanction, &c. Particular stress has been laid on the conflict of "wishes" on maladaptation to environment, on the fear of death, and on defence mechanisms before an intolerable situation; the object being to bring all the war neuroses under two heads—the "conversion hysterias" and the "anxiety neuroses."

Classification of Main Types of War Neuroses.

With a view to determining the sufficiency of suggestibility as a cause of functional nervous disorders, let us endeavour to classify the main types of the war neuroses, beginning with obviously hysterical, "suggested," cases and passing to those which show more and more clearly the need for other explanations.

1. A highly "nervous" soldier is hit on the forearm by a piece of shell. His arm drops to his side, and the thought at once occurs to him that he has lost the use of it. The entire limb becomes functionally paralysed. Here we have a clear case of suggestion acting under the influence of fear.

2. After an accident in civil life a man had long ago suffered pain or impaired mobility. A slight bruise in the same region on the battle-field produces functional hyperæsthesia or paralysis. The hyperæsthesia gives place to anæsthesia, or with recovery of movement a condition of extreme incoördination ensues. The influence of suggestion

¹ Four previous communications on this subject appeared in THE LANCET of Feb. 13th, 1915 (p. 316), Jan. 8th (p. 65), March 18th (p. 606), Sept. 9th, 1916 (p. 461).

⁴ THE LANCET, Nov. 3rd, 1917, p. 878.

is here fairly obvious. The soldier may even admit that the bruise revived the memory of his former accident. But is it necessarily and always true that hyperaesthesia has been converted into anaesthesia by suggestion or that the incoördination can be imitated volitionally?

3. In childhood certain spasmodic movements were temporarily induced by a severe fright. Of this the soldier has lost all memory. Sudden fear in the trenches revives this disordered movement, which persists for many weeks. The influence of suggestion is here less sure. But even if suggestion can explain the origin it cannot account for the long persistence of the movement, which may even continue during sleep. But if (as is usual) it ceases during sleep can it be supposed that each morning on waking the patient receives a fresh suggestion? Do we not gain a clearer insight into the condition by regarding the movement as a dissociated emotional expression inherent in the waking personality of the patient, especially when this view leads us to cure the disorder by reviving in the patient the memory of the original trouble, and thus helping to restore his normal personality?

4. A soldier in previous good health is buried owing to a shell explosion. After a period of stupor or confusion (perhaps preceding, accompanying, or following excitement, depression, or fugue), he "comes round" mute and amnesic, but he has clearly not quite returned to his normal self. Here there is no evidence of suggestion, but it is possible that suggestion may have influenced the patient when the state of confusion or stupor was passing away. By means of hypnosis memories of a patient's thoughts or environment during confusion or stupor may often be recovered. Hypnotic investigation may therefore serve to clear up this point. Yet even if loss of speech had been suggested during recovery from confusion or stupor, suggestion is impotent to explain such a patient's loss of memory. The soldier may confess to having felt some previous fear, but what man has not at some time had that experience in the trenches? There is often no evidence of any mental conflict before or after burial. But he may have been unconsciously repressing some tendency to action. Here hypnosis may again prove of use in revealing the presence of such past conflict or inhibition. It cannot be said that mutism and amnesia are obvious measures of escape from the firing line; and amnesia can only be called a defence mechanism in the sense that, like stupor, it safeguards the patient from suffering further emotion. In such cases, may we not suppose that the shock of an excessive emotion (or commotion) is adequate to produce an abnormal, stuporose, or confused personality, on emergence from which the memories of events relating thereto are necessarily lost, mutism persisting as a piece of dissociated behaviour expressive of the mental disturbance?

5. A soldier suffers pain in one or more limbs consequent on burial or a wound; or the application of a splint to his wounded limb results in prolonged immobility. He gradually develops a functional condition of muscular contraction or paralysis. There is no evidence of suggestion here. The patient is usually quite unable to account for the onset of his condition, but more careful mental exploration⁵ in the waking or hypnotic state is likely to throw light on the matter. Without this exploration all such facile explanations as the wish to escape from an unpleasant situation, the habitual persistence of immobility, the desire for a pension or for discharge from the Army, are scientifically worthless.

6. A soldier has for several months been suffering from self-reproach, owing to some act he has committed; subsequently he develops a functional disorder. For instance, he has shot at the uplifted arm of a surrendering enemy, whose arm drops helpless as he falls to the ground; later the patient's arm is slightly injured, and it becomes completely paralysed. Or he has long worried over past sexual abuse; and on breaking down from the strain of warfare he develops washing-like movements of the hands, symbolic of ridding himself of his impurity. Or he has reproached himself with causing the death of a comrade; and on breaking down he begins to suffer from visual hallucinations of seeing an avenging finger pointing at him, or from auditory hallucinations of hearing an accusing voice, or from the conviction that he has sinned unpardonably, &c. Suggestion

is powerless to account for these various examples of loss of control over bodily or mental processes. They are clearly the result of imperfectly solved conflicts, the more or less repressed, dissociated complex finding expression in motor, sensory, or ideational disorder. For with the exploration of their origin, their explanation to the patient, and his increasingly successful efforts to face and to solve the conflict his troubles come to an end.

But even if we admit that suggestion may act on the involuntary nervous system, that suggestion plays but a small part in the causation of the war neuroses, and that extreme emotion and conflicting complexes are by far their most important determinants, there still remains for consideration to what neural level functional dissociation may extend.

LIMITS OF DISSOCIATION.

Cases frequently occur in which the sudden recovery of lost memory is accompanied not merely by the restoration of speech, not merely by the cessation of spasmodic movements, but also by a marked change in the entire facies of the patient. He not only (as he states) feels, but he also looks, another person. His pupils, pulse-rate, and skin colour regain their normal condition. We may consider their previous abnormal state as due to the persistence of emotional expression, either uncontrolled by, because dissociated from, the normal personality, or belonging to an "ultra-emotional" personality which held sway owing to dissociation of the normal personality.

In the third of these contributions I suggested the general resemblance of certain cases of functional hyperaesthesia to the features of disordered sensibility described in cases of thalamic over-action, where the optic thalamus has been cut off from the normal control exercised by the cerebral cortex. Can the effects of loss of higher control in the war neuroses be similarly manifested in disorder of the sympathetic and reflex systems?

As a rule, the nystagmus, clonus, and rombergism observed in functional disorders are clearly distinguishable from those occurring in organic cases. The nystagmus is rather of the nature of an unsteadiness, the clonus is only obtained at a particular angle of flexion or degree of tension, the rombergism disappears when the patient's attention is distracted from the fear of falling. But everyone with sufficient experience must have occasionally seen cases where these disturbances in a clearly functional case are indistinguishable from truly organic disorders, just as a so-called hysterical convulsion may occasionally be indistinguishable from one due to so-called idiopathic epilepsy.

It is a question of what neural levels may be involved as the result of functional dissociation and loss of control. In his zeal to limit the manifestations of "pithiatism" to the sphere of volitional activity Babinski refuses to believe that the patellar reflex can ever be exaggerated in the functional neuroses; and neurologists holding such views delude themselves by using the epithet "brisk" in place of "exaggerated." But will any dispassionate observer deny that in the war neuroses the knee-jerk can be as exaggerated as in disseminated sclerosis, at the outset of which, by the way, we may recall the appearance of various "functional" disturbances?

The Plantar Reflex.

Let us consider in similar fashion the plantar reflex. In many cases of war neurosis no response is obtainable, or an extension of the toes may result from plantar stimulation, especially when there is well-marked hypertonus of the extensor muscles. Often this extensor response is clearly of a voluntary character, and is associated with strong flexion at the ankle; but in some cases, especially, of course, where the disturbance of consciousness has been severe after burial, a temporary extensor response may be obtained which is indistinguishable from one resulting from organic interference with the pyramidal tract.

The appearance of the extensor response at the close of an epileptic convulsion can only be due to a temporary loss of higher control arising from exhaustion of the inhibiting paths. May not such loss of control sometimes as well arise through functional dissociation? A case has been recently reported to me where the emotional excitement consequent on the revival, during hypnosis, of terrifying repressed incidents of trench warfare, produced a temporary extensor plantar response.

⁵ I prefer the term "exploration" to "analysis," alike because it is more exact, and because it does not imply adhesion to any special "school."

Clearly, further investigation of the plantar response under these and other conditions is urgently needed. In many cases of asymmetric plantar reflex I have found that on the side on which the flexor response is weaker or absent, the knee-jerk and the abdominal reflex are also weaker than on the opposite side, and the cutaneous sensibility is also diminished. Sometimes this association is reversed. These were all purely "functional" cases. Here, again, we need further observations.

Hypothesis of "Reflex" Origin of Certain Disorders.

It is easy to hold to the clear diagrammatic view that all functional neuroses are confined to disturbances of volitional activity, and that where disorders of the reflexes or of the vaso-motor system occur, or where sweating, muscular hypotonus, hyperexcitability, &c., arise, they stamp the case to be one of Babinski's "reflex" cases. Such a simple view, like the old conception of aphasia, overlooks many difficulties. For instance, the so-called reflex phenomena are usually limited to the hands or feet, whatever the site of the wound; they may occur in patients who have not received any wound at all; they are very rare in wounded patients who show no signs of paralysis or contracture; the contracture or paralysis is always amenable to psycho-therapeutic methods. That the vaso-motor and other disturbances do not disappear as rapidly as the paralysis or contraction is no proof that they are produced by reflex causes.

Babinski and Froment have observed⁷ that the abolition of the plantar reflex, the muscular and nervous hyperexcitability, and the slowness of contraction, characteristic of their "reflex" cases, are closely associated with hypothermia. Warming the affected limb abolishes these abnormal conditions. But this is no proof that they are of "reflex" origin. It will be recalled that after the division of afferent nerve fibres in his arm, Head found that a cold day would throw its state back several weeks; the just-acquired epicritic system was depressed, leaving the more primitive protopathic system alone in activity. That is to say, higher and more recently acquired systems of sensibility and reaction are prone to be inhibited or dissociated by cold and to be reintegrated by warmth.

Babinski and Froment have also observed⁸ that in their "reflex" cases of paralysis and contracture chloroform anaesthesia often causes at a certain stage an exaggeration of the tendon reflexes and a well-marked clonus on the affected side, while in healthy people they fail to get any similar appreciable effect. But these observations on the effect of chloroform anaesthesia, as well as those on the effect of warmth on the reflexes, need to be carried out on purely functional cases where there can be no question of "reflex" causes.

Theory of Loss of Some Higher Control or Endocrinic Disturbance.

If we discard the hypothesis of the "reflex" origin of these disorders what explanation can we offer in its stead? On the one hand, we may regard them as consequent on the loss of some higher control, due to emotional disturbance, in which case their limitation to a single region is due to the same cause as the limitation of the voluntary muscular paralysis or contracture. Or, on the other, we may regard them as immediately due to some disorder of the internal secretions, in which case their localised manifestation may be attributed to a local nervous predisposition, either congenital or acquired. Thus, Babinski and Froment⁹ have described certain cases of "reflex" disorder in which a smaller pulse was observed on the affected side. But d'Oelsnitz and Boisseau¹⁰ find that the pulse is small in such cases on the unaffected side also, and they regard the inequality as merely the accentuation of a constitutional or acquired disposition. Boisseau¹¹ observes that after cure the previously smaller pulse (on the affected side) may become larger than that on the opposite side, as the limb becomes warmer and less cyanosed. Clearly further investigations are needed on this subject.

But in either event, whether the so-called "reflex" phenomena are due to loss of higher control or to endocrinic disturbance, emotional disorders are fundamentally responsible for the condition. It only remains to determine

by investigation whether these neural disturbances are produced directly by the emotion or indirectly through the action of the "emotional centres" on the endocrine glands. The one reliable method of determining whether there is any disorder in internal secretion would seem to consist in ascertaining if the patient is unduly susceptible or insensitive to doses of the various glandular extracts, the normal effects of which have been observed by control experiments on healthy persons.

I recall two cases of "shell shock" lying side by side in a clearing station in Flanders. I drew a cross with my finger on the abdomen of each, and obtained in the first a vivid *tache cérébrale*, bright red in colour, while the second yielded an equally vivid image of a cross in white—a phenomenon now recognised to be due to arterial hypotension, such as may arise from adrenal insufficiency. Here, then, conceivably we have two patients respectively suffering from an increased and a diminished tone of the sympathetic system, associated with hyper- and hypo-adrenalism.

In a series of cases examined by me within a few hours after the onset of "shell shock," I could find no sphygmomanometric evidence of increased blood pressure, nor by Fehling's fluid could I detect (save in one case) the slightest trace of sugar even in the first urine passed by these patients since they left the trenches. But sympathetic (or vagal) neuroses may be associated with glandular exhaustion, as well as with glandular over-action.

We need a careful record of the effects of glandular extracts on the emotional condition of cases of war neuroses, and of their effect on the psycho-galvanic reactions and on the reaction times of such patients in association tests.

We are as yet uncertain of the range of action of the sympathetic system, and hence of the extent of its influence in the war neuroses.¹² That it can control the tone of voluntary muscles and affect the steadiness of their contraction there is little doubt. Can it also produce the osteoporosis and muscular atrophy which is observed in many so-called "reflex" cases? Every experienced physician must have occasionally met with a surprising degree of atrophy, alike in cases where there has been some local wound or central concussion and in cases where there has not. This atrophy is often very slow to disappear and in the experience of some is intensified by the returning use of the affected muscles. In certain cases it may arise from vaso-motor disturbances in the cord, induced by the sympathetic system. In addition to the collection of data bearing on this obscure subject we need a series of investigations by modern methods on the electrical reactions of functionally disordered muscles.

In this country, at least, we have been paying so much attention to the mental aspect of the war neuroses that a detailed examination of the accompanying bodily symptoms has been generally neglected. We have yet to ascertain what symptoms usually occur in combination. My own experience, for example, leads me to think that a feeble or absent plantar response is usually associated with a sluggish reaction of the pupils to light and with a tendency to clonus and catatonia, while an unusually brisk flexor plantar response is associated with an extra-active pupil reaction. Rigidity of the limbs often seems to go with hyperaesthesia, weakness with anaesthesia. But much more information is needed on this subject.

A more careful study is also needed of the mental and physical changes occurring during recovery. A most promising subject of investigation would be the changes that terrifying dreams undergo as the patient improves—victory, perhaps, replacing defeat in his dream battles, and civil elements gradually intruding into the dreams of warfare.¹³

TREATMENT.

Those who have had most experience in war neuroses are generally agreed that different physicians attain different degrees of success according to their particular mode of use of the same treatment, and that there is hardly any form of treatment recommended that has not its value in appropriate

⁶ Cf. Dejerine: *Rev. Neur.*, 1915, xxii., No. 19.

¹² In agreement with Pighini (*Riv. sperim. di Frenet.*, 1917, xlii., 288), Orr and Rows have pointed out (*Brain*, 1918, xli., 19) how intimately the sensori-motor and psychic areas of the cerebral cortex are associated with the sympathetic system, and hence how disordered functional activity of the former may spread through the latter to lower centres in the mid-brain, bulb, and cord, causing dilatation of the pupils and cardio-vascular and other disturbances.

¹³ Cf. D. E. Core: *THE LANCET*, August 10th, 1918, p. 169.

cases. Nearly all of us have learned to ban the routine use of hypnotic drugs; yet in some cases they are unquestionably valuable. An unbiased record is needed of such successes and failures. So, too, we have learned that it is usually disastrous to send a patient to employment or amusement in the hope that he may forget all his worries and solve his conflicts by neglecting them. Yet in some cases this treatment is successful. Again, therefore, we require a careful record of the special determinants which should guide our adoption of the policy of sending mentally uncured neurasthenic cases out of hospital for work or golf.

Experience has also shown that a certain class of patient on recovery of the use of a functionally disabled limb regains his normal mentality and is able to throw off all his psychic disturbance. We need a record of the particular class of case in which this treatment is successful. We need to follow up the cases where the psychic disturbances have been thus neglected or where they have been indirectly treated, and to record, not only the speed, but also the permanence of the cure. When the psychic disturbance is allowed to persist behind the scenes, a showy lightning removal of some bodily functional disability is no true cure at all; the same (or some other) disability will later develop on the slightest provocation. In this connexion I would point out how prone the enthusiastic devotees to one special mode of treatment are to self-deception. I have repeatedly had some method demonstrated to me by its advocate, who has said to me: "See what a marked improvement (say) in stammering has been effected by my treatment," whereas to a dispassionate observer the benefit is almost, if not quite, imperceptible.

In my early experience of shell shock I came to lay great stress on disturbances of personality, and I regarded the amnesia and the bodily disorder, mutism, tremor, incoördination, or spasmodic movement, so commonly observed in cases seen soon after their onset, as the expression of this change of personality, due, like it, to some functional dissociation. Accordingly, I adopted the therapeutic principal of restoring the amnesia with or without the aid of hypnosis; and with the restoration of the amnesia came a restoration of the speech and a resumed control of the bodily movement. Brown,¹⁴ who pursued the same method, came to the conclusion that its efficacy was due not so much to the reintegration of the normal personality as to the working off (abreaction) of the repressed emotion. On the other hand, I appeared to produce as good results by discouraging the patient from giving rein to his emotions during treatment. But clearly a series of carefully controlled investigations is required, in which equal numbers of patients are exhorted to restrain and to express their emotions, and the resulting effects compared. Later I began to treat the bodily disabilities first and the mental disturbances after. We have yet to discover which order of treatment should be adopted in different cases.

Electrotherapy and Hypnosis.

Lastly, there remain for consideration and unbiased investigation the debated values of electrotherapy and hypnosis. Each, if improperly used, has its dangers. I have seen vast numbers of stammerers whose condition, I am convinced, has been produced by the alarm they experienced during the electrical treatment of their previous mutism. I have observed similar results from the application of faradism to other functional motor disorders. Yet I should err in recommending that electrotherapy should never be employed. What we need is an inquiry into the special conditions in which it is beneficial and the particular methods which free it most completely from danger.

Perhaps against no method of treatment has there been greater prejudice than against hypnosis. Early in the war I remember the commandant of one military hospital telling me that he would not in any circumstances countenance its employment because the reputation of his unit would suffer thereby. I have read pages of vituperation against hypnosis written during the war by medical men who had had no personal experience of its use. Imagine what would be our attitude towards a physician who wrote in condemnation of a particular drug which he had never tried. There is, however, an instinctive aversion from the practice of hypnosis which seems to justify almost any attack against it. I recognised it for a long time in myself. Hypnotism savours of the

uncanny, mysterious, and unknown. One's first attempts at hypnotism demand even more self-mastery than one's first sight of an operation.

In these circumstances what an urgent need there is for a dispassionate investigation of its merits and defects, of its uses and abuses! It has been claimed that hypnosis makes the patient for ever dependent on the hypnotiser. We may ask, Must it do so, any more than exploration of the mind in the waking state need make him dependent on the explorer? We need to inquire into the different results in this respect arising according to the different modes of hypnotic treatment adopted. It has been urged that hypnotism gives the patient a temporary relief, like a hypnotic drug or a brandy-and-soda. That, again, must depend on the method of its use.

Here, too, we need careful inquiry into the comparative values of hypnosis as a method of mental reintegration (unearthing repressed complexes) and as a method of somatic reintegration (restoring bodily disabilities by direct suggestion). And, above all, we need an inquiry into the subsequent permanence of cure of those patients who have been treated by either of these two methods with and without hypnotism.

Is it too late to hope that systematic inquiry may yet be begun, at least along some of the lines which I have indicated in this paper? Up to now the field has been almost wholly neglected. Far from being barren, it is rich with the possibilities of valuable results.

INCIDENCE OF *ENTAMOEBA HISTOLYTICA*

AND OTHER INTESTINAL PROTOZOA AMONG 400
HEALTHY NEW ENTRIES TO THE ROYAL NAVY.

By H. A. BAYLIS, M.A.,

ASSISTANT, DEPARTMENT OF ZOOLOGY, BRITISH MUSEUM (NATURAL HISTORY); PROTOZOOLOGIST (TEMPORARY), ROYAL NAVAL HOSPITAL, HASLAR.

THE large amount of work that has been done in connexion with amoebic dysentery during the last three years has opened up a number of questions, not the least interesting of which is to what extent carriers of *Entamoeba histolytica* exist among the civil population in countries with a temperate climate. Some inquiries on this point have already been made in this country, more particularly by the energetic group of workers at the Liverpool School of Tropical Medicine, who have been engaged primarily in the protozoological investigation of the stools of soldiers invalided from the various fronts.

A summary of the results originally published in their earlier papers,^{1,2,3,4} together with more recent data, was presented by Professor Warrington Yorke⁵ before the Society of Tropical Medicine and Hygiene in June, 1918. An instructive table is there given, in which the results of the examination of various classes of civilians and young recruits are compared with those obtained in the course of routine examinations of convalescent soldiers, both dysenteric and non-dysenteric. Among 450 civilian patients in the Liverpool Royal Infirmary it was found that 1.5 per cent. were carriers of *E. histolytica*, while the examination of 246 children under 12 years old in the Liverpool Children's Infirmary revealed 0.8 per cent. "positive."

The incidence among recruits, 18 to 19 years of age, who had been in a training camp for various periods not exceeding three months, was considerably higher (5.2 per cent.). This may be partly accounted for by the fact that there were also in the camp some men who had returned from the Mediterranean area, and from whom the recruits might have acquired their infections. This hypothesis, however, as the author states, would not altogether account for the facts, since it was proved that many of the recruits had almost certainly been infected before going into the camp.

From these results it appears therefore that in some sections of the civil community in England there may be carriers of amoebic dysentery to the extent of from 1 to 5 per cent. of the apparently healthy population. If this is the case, questions naturally arise as to the wisdom or necessity of spending much time and trouble in discovering and attempting to cure such carriers, as has been done to a great extent among the naval and military forces during the war.

On the publication of the statistics above referred to, it was suggested to the Admiralty by Surgeon Captain P. W. Bassett-Smith, C.B., R.N., that the protozoologist at Haslar

¹⁴ THE LANCET, August 17th, 1918, pp. 198, 199.

should undertake an inquiry on similar lines, making use of new entries to the Navy at Portsmouth as a sample of the material from which the Navy is recruited. Accordingly, instructions were given by the Admiralty, and arrangements having been made through Surgeon Lieutenant-Commander P. Fildes, R.N.V.R., in charge of the laboratory at Haslar, with the medical officers of the Royal Naval Barracks, Portsmouth, and one or two other establishments in the neighbourhood, for supplies of material to be sent to the laboratory, the work was begun in July.

I. Material.

Altogether specimens of the stools of 400 men who had just entered the service were examined.

With the exception of a few from the Royal Marine Barracks, Eastney, and a still smaller number from the Royal Marine Barracks, Porton, all these came from the Royal Naval Barracks, Portsmouth.

The new entries at the barracks were attending in daily batches at the sick bay for throat-swabbing, in accordance with the routine for the detection of carriers of the meningococcus. It was found convenient, therefore, to arrange that five of these men daily should be selected at random and specimens of their stools collected and sent to Haslar. The men came from all parts of the country, and this system of random selection was calculated to ensure that the cases examined would not be representative of any one particular district or section of the civil community, but would be a fair sample of the whole.

Owing to the pressure of work on the medical staff at the barracks, and other considerations, it was not found possible to obtain the histories of all cases sent for examination, but it was thought sufficient to make special inquiry as to the history of each case found to be a carrier of *Entamoeba histolytica*. A scheme of questions was drawn up, as to whether the man had ever been abroad, his occupation, residence, &c., during civil life, and whether he had ever had symptoms of intestinal disease. These questions were put to each man as occasion arose, and the answers provided the "histories" to be given later.

II. Technique.

As it was desirable to examine a fairly large number of cases, and considerations of time and convenience of arrangement with the barracks had to be taken into account, it was decided to allow only one examination in each case. It was therefore necessary to define, as a standard, exactly what constituted "one examination." In practice, in the routine examination of patients in the hospital, it had been found that the exhaustive inspection of two cover-glass preparations of thin emulsions of each stool was generally sufficient for one examination (i.e., if cysts or amoebae of *E. histolytica* were present in any given specimen, they would generally be detected by this method, unless the infection was a very slight one). In fact, records were to hand showing that two preparations had been the average number devoted to each first routine examination of new cases for many months at Haslar.

This standard was therefore adopted in dealing with the whole of the 400 new entries; it had the advantage of rendering the results more nearly comparable with those obtained for convalescent dysenterics and other patients examined in the hospital, and these will be given for the sake of comparison, being now published for the first time in full.* It also happens to be identical with the standard adopted for "one examination" by the Liverpool workers, (l, p. 412) and therefore makes the results strictly comparable with theirs, except in so far as the personal element has to be considered.

From each specimen, then, two small drops of emulsion were placed side by side on a slide, and each covered with a cover-glass. As a rule, one emulsion was made in normal saline, the other in Weigert's iodine solution, and the "loopfuls" of faeces were usually taken from different parts of the specimen, to allow for the possibly unequal distribution of the protozoa. The two preparations were then gone over completely under the microscope with the aid of a mechanical stage, using a 1 inch objective and a No. 3 ($\times 8$) ocular. If no protozoa were found, the case was recorded as negative. If any cysts of doubtful nature were found, it was sometimes necessary to make further preparations, but this, of course, does not alter the standard of "one examination."

III. Results.

The results of the investigation may be most conveniently stated in the form of a table. It may be mentioned here that in no case were any active amoebae found. In all cases

* A note on the protozoological findings in the first 394 cases examined at Haslar has been published in the Medical Research Committee's Report on Dysentery Cases received from the Eastern Mediterranean. (Special Report Series, No. 6, III., 1917, p. 24.)

the terms *Entamoeba histolytica* and *Entamoeba coli* refer to the encysted forms. Table I. shows the incidence of *Entamoeba histolytica* and other intestinal protozoa among new entries to the Royal Navy and Marines at Portsmouth. Total number of cases examined = 400. These men came from all parts of the British Isles, and were in no way representative of this district in particular.

(a) Total number of cases found to be infected. (b) Col. (a) as percentage of the cases. (c) Pure infections. (d) Mixed infections.

TABLE I.—400 New Entries. TABLE II.—888 Patients.

| Organism. | (a) | (b) | (c) | (d) | (a) | (b) | (c) | (d) |
|--|-----|-------|-----|-----|------|------|-----|-----|
| Protozoa of any kind ... | 120 | 30.0 | 110 | 10 | 202† | 22.7 | 179 | 23 |
| <i>Entamoeba histolytica</i> ... | 10 | 2.5 | 9 | 1 | 52 | 5.9 | 35 | 17 |
| <i>Entamoeba coli</i> ... | 94 | 23.5 | 86 | 8 | 118 | 13.3 | 104 | 14 |
| <i>Entamoeba nana</i> ... | 3* | 0.75* | 1* | 2* | — | — | — | — |
| <i>Giardia</i> [<i>Lambia</i>] <i>intest.</i> { <i>adults</i> ... | 22 | 5.5 | 14 | 8 | 47 | 5.3 | 41 | 6 |
| <i>Chilomastix</i> [<i>Tetramitus</i>] { <i>mesnili</i> ... | 1 | 0.25 | — | 1 | 2 | — | 1 | 1 |
| <i>Trichomonas hominis</i> ... | — | — | — | — | 2 | — | — | 2 |

* The figures for *Entamoeba nana* cannot be regarded as trustworthy, as no special effort was made to search for it, and when present in small numbers it may have been frequently overlooked.

† Including 3 cases of *Entamoeba nana* (which was only recognised during the latter part of the period covered, and even then probably often overlooked) and 1 case of an amoeba of the *limax* type.

Before discussing the significance of these results it will be well to compare them with those derived from the examination of cases in the Royal Naval Hospital, Haslar, between March, 1916, and July, 1918, most of whom were convalescent dysenterics, or were suffering from intestinal disorders of various kinds, and had been serving abroad, many of them in the Mediterranean area. Table II. shows the incidence of the various protozoa among 888 such cases. Account is taken only of first examinations, in order to make the results more comparable with those already given. When further examinations are included, the percentages of "positives," of course, increase with every additional examination.

It has not been possible to classify the cases included in Table II. into men who have and men who have not suffered from dysentery, as the laboratory records do not supply sufficient information as to their history. It should be borne in mind, however, that some of the cases included in the table were at the time of examination actually in an acute phase of amoebic dysentery, or, at all events, were passing active amoebae. At the first examination free amoebae were found, either alone or together with the cysts, in nine cases. Subtracting these from the 52 in column (a) in the table, we have only 43 *E. histolytica* carriers, as distinct from actual cases. This brings the percentage 5.9 in column (b) down to 4.8.

Comparing the two tables (I. and II.), therefore, we find that the incidence of the "harmless" protozoa severally—*Entamoeba coli*, *Lambia intestinalis*, and *Tetramitus mesnili*†—and that of protozoa taken as a whole is actually higher among the "new entries" (more or less representative of the civil population of the British Isles) than among the men who have been in regions where they would presumably be more likely to be exposed to infection; while the presence of *Entamoeba histolytica*, though of considerably lower frequency than among the latter, is still about half as frequent. It must be remembered that all the figures probably err on the side of being too low, owing to the small number of examinations of each case, and that they give a totally inadequate idea of the actual incidence of infection. In Section V. an attempt will be made to estimate the probable amount of error in the case of *E. histolytica*, and it may be assumed that at least an equal amount of correction would be necessary in the case of the other protozoa.

IV. Histories of the "New Entry" Cases Positive for *Entamoeba histolytica*.

A summary may now be given of the histories, as far as they are known, of the ten cases found to be carriers of *E. histolytica*.

CASE 5.—Age 18; farm labourer; usual place of residence, Petlar, Shetlands (in a village with 100 inhabitants). States he has always lived at home until entering the Service, working on a small farm. Has never been abroad. Has never had symptoms of intestinal disease.

† *Trichomonas* was not found at all among the new entries.

CASE 27.—Age 32 years 9 months; plumber; residence, Reading. Had resided at Baroda, India, for three years (February, 1915, to May, 1918), and had had a slight attack of dysentery there in 1917.

CASE 40.—Age 33; schoolmaster; residence, Preston. States he lived in the country in Lancashire until 12 years of age. Has never been abroad. Has had recurrent attacks of diarrhoea at intervals of nine months, lasting three or four days; last attack four months previous to examination.

CASE 44.—Age 21½; fitter and tailor; residence, West Bromwich, Birmingham. Has never been abroad. Has never had symptoms of intestinal disease.

CASE 84.—Age 18; outside porter; residence, East Grinstead, Sussex. Never abroad. Never had symptoms of intestinal disease.

CASE 181.—Age 18; bootmaker; residence, Kettering, Northants. Never abroad. Never had symptoms of intestinal disease.

CASE 211.—Age 18; bricklayer's labourer; residence, Wolverhampton. Never abroad. (This case was admitted at Haslar with "catarrh," developed pneumonia, and died before further information could be obtained. At the post-mortem examination made by Surgeon-Lieutenant S. L. Baker, R.N., nothing abnormal was found in the intestines.)

CASE 374.—Age 38; fireman in Merchant Service; residence, when in England, Rotherhithe. Had been in the service of the Orient Line since 20 years of age. Never had symptoms of intestinal disease.

CASE 389.—Age 19; fisherman; residence, Portstewart, Coleraine, Co. Derry, Ireland. Never abroad. Never had symptoms of intestinal disease.

CASE 393.—Age 27; ticket collector; residence, Queenstown, Co. Cork, Ireland. Never abroad. Never had symptoms of intestinal disease.

The following points of interest may be extracted from the preceding histories. Out of 10 carriers—

(a) Eight had never been out of the British Isles. One had resided abroad (in India) (Case 27). One had travelled extensively in the East (Case 374).

(b) Seven at least had never had symptoms of intestinal disease. (In regard to Case 211 information is lacking.) One had had dysentery (Case 27). One had had recurrent diarrhoea (Case 40).

(c) Five had lived exclusively in England. One had lived exclusively in Scotland. Two had lived exclusively in Ireland.

Out of the eight carriers who had never been abroad only one (so far as is known—*vide* Case 211) had ever had symptoms which might be attributable to his infection with *E. histolytica*.

Age and occupation appear to have no bearing whatever on the incidence of infection.

As far as the small number of cases justifies such a conclusion, infection appears to be pretty evenly distributed within the British Isles.

It is to be observed that two of the cases cannot strictly be considered representative of the population of these islands (Cases 27 and 374). The subtraction of these from the total gives 2, instead of 2.5, as the percentage of incidence (see column (b), Table I). There is reason to believe, however, that the real incidence is much greater, and certainly not less, than 2.5 per cent., as will be seen from the arguments in the following section.

V. Estimation of the Probable Incidence of *E. histolytica* had all Cases received numerous Examinations.

It is well known that infection cannot be detected at every examination, even in cases who occasionally pass very large numbers of cysts. The limitation of examinations to one for each case gives results which are only a fraction of the actual number of carriers probably existing in any given series of cases. Various attempts have been made to calculate the minimum number of examinations necessary in practice, and also to work out the margin of error where the number of examinations is too small.

Dobell,⁶ after much study of the matter, has expressed the opinion [p. 43] that more than three negative examinations must be made on an untreated case before it can reasonably be said to be free from *E. histolytica*, but that it is probable that in three examinations not more than half to two-thirds of the infected cases will be detected. Six examinations are suggested as a minimum in practice.

The Liverpool workers^{1, 2} have also studied this question at some length, and their final conclusion is that three examinations will only discover 50 to 57 per cent. of all actually positive cases.

Owing to the regulations regarding "negative examinations" of convalescent dysenterics in the Service, the number of examinations in the Haslar series has always been too small from this point of view. The following figures show the increase in the percentage of positives for *E. histolytica* at each examination as far as the third. The number of cases examined more than three times was so small that it has not been thought worth considering in this connexion.

Out of 888 cases examined at least once, 52 (or 5.9 per cent.) were found positive at the first examination.

Out of 335 cases examined at least twice, and negative at the first examination, 12 (or 3.6 per cent.) were found positive at the second examination.

Out of 164 cases examined at least three times, and negative at the first and second examinations, 3 (or 1.8 per cent.) were found positive at the third examination.

It is calculated, therefore, that if the whole of the 888 cases in the series had been examined twice the percentage of positives found would have increased from 5.9 to 9.5, and if all had been examined three times a still further increase to 11.3 would have taken place.

These figures, as far as they go, are so closely similar to those given for a series of 1713 cases by the Liverpool workers [2, Table XI.] that it is assumed that had more examinations been made of the whole Haslar series the percentage of positives would have continued to increase at the same rate for subsequent examinations as in the Liverpool series, and that conclusions based on that series may therefore be applied to the present inquiry.

In the Liverpool series referred to it was calculated that 33.4 per cent. of all cases that would have been found positive in six examinations were discovered at the first examination; and six examinations were calculated to be enough to detect the great majority of infections. It appears, therefore, that if the percentage of positives discovered at the first examination of any series be multiplied by 3 we shall have a moderate estimate of the percentage of positives actually existing in that series.

Applying this rule to the present series of 400 "new entries," where 2 per cent. were actually found positive at the first examination, we find that the real incidence would, in all probability, be not less than 6 per cent. Furthermore, since these men were not selected cases in any way, and were fairly representative, it is believed, of the general adult male population of the British Isles, we have the rather startling conclusion forced upon us that something like 6 per cent. of such a population are carriers of *E. histolytica*, and this figure might be found to be still too low, if a large series of cases were taken and the number of examinations of each were indefinitely increased.

VI. The Pathogenicity of the Cysts.

Granted that some such percentage of carriers as that indicated in the foregoing section exists among the population, it is desirable to find out to what extent they are a danger to themselves or to others with whom they are associated. The data on this subject are unfortunately at present quite inadequate.

It is now recognised that the cat is a suitable animal for laboratory experiments with *E. histolytica*, but it is not always easily infected, and young kittens have been found to be more susceptible than older animals.

It was thought desirable to test the cysts from the new entries from the point of view of pathogenicity, since it was not certain that the strains of the parasite found, though morphologically identical with those from dysenteric patients, possessed the same pathogenic properties. Accordingly two kittens were obtained and kept in readiness, soon after the first few "positives" were recorded. Unfortunately some time elapsed before another positive case was available, and by that time the kittens were almost half-grown, which possibly accounts for the failure of the experiments. The faeces of the two animals were examined from time to time before the infection experiments took place, and no parasites except those normal to cats were detected.

Experiment 1.—On Oct. 29th at 6.30 p.m., each kitten was given 10 c.c.m. of an emulsion in normal saline of faeces from Case 374. (The history of this case was not known at the time.) The emulsion was made in the morning of the same day, strained through muslin to remove gross particles, and left standing at room temperature till the evening. It was examined before use to make sure that it contained a fair number of healthy cysts. The injection was given by Dr. Filde with a 10 c.c.m. syringe attached to a No. 8 soft rubber catheter, which was lubricated with glycerine and passed down the oesophagus. The two kittens were kept under observation and their faeces examined daily (with few omissions) until Nov. 15th (17 days from the beginning of the experiment). On one or two occasions there was some diarrhoea; with mucus in the stools, but no amoebae were ever found and none of the signs of acute dysentery were observed.

Experiment 2.—On Nov. 15th, at 6.30 p.m., with the same technique as before, the kittens received injections (given by Dr. Filde) of two separate emulsions, as follows: Kitten 1 received 10 c.c.m. of emulsion from Case 389 containing numerous healthy cysts, the average diameter of which was 8 μ (a very small strain). Kitten 2 received 10 c.c.m. of emulsion from Case 393, in which there were many healthy cysts of typical average diameter (13 μ). As in the former experiment, the faeces of both kittens were examined almost daily, until Nov. 29th

in the case of No. 1, and until Nov. 30th in the case of No. 2, and though there were again occasional diarrhoeic stools, with mucus, no serious signs arose and no amoebæ were found.

Kitten 1 was killed (by coal gas) on Nov. 29th and a post-mortem examination failed to reveal any lesions of the mucous membrane of the intestine, or any amoebæ in the contents or in scrapings from the surface. Kitten 2 was similarly killed and examined on Dec. 2nd. No amoebæ were found in the intestinal contents or in scrapings from the mucous membrane. The rectum showed prominent lymphatic nodules, but sections of these revealed nothing of a pathological nature.

It is worth recording that both the kittens were found to be fairly heavily infected with *Lambia* (apparently the human species). The cysts were first found in the faeces of No. 1 on Nov. 2nd (four days after the first infection experiment) and in the faeces of No. 2 on Nov. 20th (five days after the second infection experiment). Cysts of *Lambia* had not been observed in any of the human stools used in the experiments, but *Lambia* is not known to be a normal parasite of the cat, and it is probable that the infection was artificially produced. The cysts were found repeatedly during the examinations of the faeces of the kittens, and numerous active forms of *Lambia* were found post mortem in the lower part of the small intestine of each.

The negative result of the experiments as regards *E. histolytica* is probably of little significance. A positive result would have been valuable, but other workers have found that experiments in the infection of cats with cysts per os are often failures, especially when the cats are too old. Dale and Dobell⁷ succeeded in infecting one kitten out of eight in this way, and the Liverpool workers⁴ one out of four. The present experiment, therefore, though negative, must not be taken as an indication that strains of amoebæ from carriers in the British Isles are non-pathogenic. Further evidence on this point is necessary before any statement of this kind can be made.

VII. Summary and Conclusion.

Among 400 healthy new entries to the Royal Navy, freshly joined from places all over the British Isles and examined once each, 10 were found to be carriers of *Entamoeba histolytica*. Of these, 8 had never been out of the British Isles, and 7 at least had never had dysentery. Taking the 8 home cases only, the percentage of infections found at a single examination is 2. This, however, is a minimum figure, and it can be calculated that the real percentage of carriers among the adult male population must be nearer to 6. If this is the case, it may be doubted whether the rigorous treatment of carriers in the Services, who have not themselves suffered from dysentery, is justified or necessary. The percentage of carriers is naturally higher among men who have served in countries where the disease, in its acute form, is endemic, and especially under the conditions of war. But in all probability, given good sanitary conditions, the ordinary carrier is not a serious source of danger to others. The view that he is a source of danger to himself, in that he may at any time develop dysentery or hepatic abscess, remains in any case to be considered, and upon this point the present inquiry offers no evidence.

Experiments on kittens were tried with a view to obtaining evidence of the pathogenicity of the strains of cysts from the "new entries." The fact that the kittens failed to become infected is not, however, regarded as evidence for the non-pathogenicity of such strains.

The writer's thanks are due to Mr. C. O. Dobell, F.R.S., for his kind suggestions as to the general lines of the work, and for some hints on the method to be employed in the infection experiments on kittens; and to Dr. P. Fildes, Surgeon Lieutenant-Commander, R.N.V.R., for the actual performance of those experiments, and for his kind assistance and criticism throughout the work.

THE ANALYSIS OF A COMPOSITE NEUROSIS.

By F. DILLON, M.B., CH.B. EDIN.,

TEMPORARY CAPTAIN, R.A.M.C.; LATE NEUROLOGIST TO 3RD ARMY, H.E.F.

As for that wandering ship of the drunken pilot, the mutinous crew and the angry captain, called Human Nature, "fantastical" fits it no less completely than a continental baby's skull cap the stormy infant.—MEREDITH, "The Tragic Comedian."

FROM time to time in the study of the neuroses of war cases are met with which disclose the combination of a war neurosis with another of different order: composite conditions in which the development of a neurasthenia or allied disorder resulting from war strain has taken place in conjunction with a pre-existing neurosis or the rudiment of one.

War neuroses, in common with others we were familiar with before the war, we know to be entities of considerable complexity. These composite neuroses, however, attain a double complexity from the synthesis of two pathologically distinct conditions. From the consequent adjustment of the treatment which this implies it is of the utmost importance, therefore, for the condition to be recognised.

The case about to be described forms an example of such a condition. It was treated at an advanced centre in France, and consequently under difficult and unfavourable conditions. It presents, however, a number of points of considerable interest, not only in the fact of the improvement which resulted from an analysis left by force of circumstances incomplete, but in the illustration it provides of several of the present-day problems of psycho-analysis.

However much the significance of the sexual factor as taught by the Freudian school may be disputed, the value of the psycho-analytic method is becoming more and more widely recognised. In the stimulating nature of the discoveries made by its means and the widening scope for investigation it has suggested, it has inspired the spirit of a sort of renaissance for psychology and psychiatry. One of the chief errors, in my view, of psycho-analyst schools hitherto has been in the mode of presentment of their subject. The results of their very important investigations have been described along lines entirely uncorrelated with the principles of normal psychology. Mechanisms and principles of mental activity have been described with no reference to what was already known on the subject. In consequence it seems that two psychologies have developed—two parallel systems, the psychology of psycho-analysis, and the academic system of the schools.

This may have been inevitable in the beginning. Jung observes that psychology had little to offer to the psychiatrist until Freud's discoveries.¹ But since the publication of "Selected Papers on Hysteria" in 1895, psychology has made very considerable advances, and a correlation between the two is not only to a large extent possible, but urgently desirable.

The process, however, has by certain authorities unfortunately been carried further. A remarkable esoteric phraseology has been evolved which has had the effect not only of obscuring the issues of the subject, but by its semi-mystical colouring has laid it open to the accusation of oneiromancy and superstition.

There is, so far as I am aware, no reason why scientific knowledge should not be expressed in clear and simple language. New mechanisms, new facts as they are brought to light, undoubtedly require new names to label them, but in this case it has been carried beyond the limits of merely technical necessity. Freud remarks: "A clear and unequivocal manner of writing shows us that here the author is in harmony with himself, but where we find a forced and involved expression aiming at more than one target, as appropriately expressed, we can thereby recognise the participation of an unfinished and complicated thought."² In this regard the elaborate and obscure terminology developed by some of the psycho-analyst pioneers raises a suspicion—however wrong it may be—that the obscurity of expression may indicate a corresponding obscurity of conception.

Account of Case.

The present case is similar in many respects to others described in psycho-analytic literature except that it gains a special interest and importance from the fact of the

conflict which was disclosed being combined with the syndrome of a war neurosis.

Pte. C. N., an intelligent young man of 23, of good social position, was admitted into hospital on July 21st, 1917. He was in a mildly depressed state, complained that he was confused in mind and that his nerve had given way in the line. When asked to describe in greater detail his mental confusion he said that when coming down in the motor ambulance to hospital he felt as if he were losing himself and didn't know where he was. He had to sit up and look around to assure himself of his surroundings. His head felt larger than its normal size and he had a heavy feeling in it as if he had had a "night out." There was "a lack of power of thinking properly" as if there were a brake on his thoughts: a definite feeling of effort was required to think. The content or scope of consciousness seemed to be restricted and smaller than normal except when he was dropping off to sleep, when, he said, his thoughts "wandered all over the place."

He joined the Army in October, 1915, and came to France in March, 1916. He remained perfectly well, acting as stretcher-bearer, until April 10th, 1917. On that day he was one of a stretcher-squad carrying a patient to a dressing station; a shell burst in the middle of them, killing three. Patient was left unwounded and a short amnesia exists for the events immediately succeeding this. He found himself some time later lying against the wall of a house, very shaky, nervy, and jumpy. He walked down to the dressing station of a field ambulance, and after two or three days was sent down to the base. He remained there for a fortnight and then rejoined his unit. It was at that time behind the line, and patient stated that he felt well, and as they were out of the shelling area his "nerves" did not trouble him. Three or four weeks before admission to hospital he was sent into the line again to F—. Then he noticed his nerve beginning to give way; shelling made him nervous, he was jumpy, shaky, and easily scared, which he had never been before. About a fortnight later he moved to a dug-out with a signboard opposite—a signboard destined to play a significant part in his neurosis. His nerves gradually grew worse, he began to have terrifying dreams, and to feel confused and "silly"—as if he could not answer questions sensibly. The following morning he had an attack of sickness and vomiting, brought on, he thought, by eating sardines from a tin previously opened, and he was sent to hospital.

There was no history of any nervous or mental abnormality in his past life and, apart from the fact that his sister had been a sleep-walker for some years, his family history was negative. On examination of the patient there was no sign of any organic derangement.

The facts described of his history and condition were elicited without difficulty. From his manner, however, it was evident that there was something more to be told, and after some hesitation he admitted, with a certain humorous shamefacedness, that a particular image was constantly recurring in his consciousness. It kept continually obtruding itself, no matter what he attempted to do. He felt it was so ridiculous that he did not care to mention it in the first instance. He could describe it in no other way than by saying it was just like a "spotted pudding."

We have here an obsessive "overweighting of a particular element in consciousness" and consequent loss of the homogeneity of mind which is recognised invariably to denote the presence of a mental conflict. The significance of this symptom was sufficient to show that we had to deal with a disorder more complex and severe than the common forms of war neuroses.

The first step in the treatment was to undertake an investigation of the obsession which offered itself for analysis. Treatment was begun on August 1st, 1917, and it will be interesting to record the material of association exactly as it was produced by the patient. The spotted pudding brought into his mind the image of the "trunk of a tree; one in a jig-saw puzzle in the ward—a white spot above it—a white rabbit—pink eyes—ferns with red flowers—Islé of Wight—Italy and Sicily—an Italian woman with a basket—wearing a navy-blue shawl—with a white edge."

At this point he stopped, and when asked to tell what was passing in his mind he became somewhat agitated and indignant, and said he repudiated the suggestion—an immoral one—that had been put into his mind regarding the Italian woman. A few further details were obtained at this interview, but from the patient's somewhat disturbed state it was considered advisable to go no further in the investigation that day.

The next morning he brought to me the following dream that had occurred to him during the night:—

I came out of a school (dirty old brick affair with courtyard), rushed past L., who was standing in the yard (dressed in dark blue), and was carried some distance (against my will) into some side streets of an unknown town.

I felt that she was hurt with me and was half afraid to meet her, yet had a deep longing to meet her. She apparently followed me (in a very dignified mood).

She came down a narrow street to where I was standing and the last I saw was a man in khaki trying to force his attention on her while she was still resisting. (I knew that his attempt to force his company on her would be unsuccessful.)

This, it is evident, is a dream in which the meaning is very little disguised. The manifest is little different from the latent content, and the elements of conflict are readily discernible.

Analysis brought to light the fact that some time before the war he had fallen in love with, and become privately engaged to, a girl much beneath him in social position. His people were aware of the attachment and bitterly opposed to it. He was not in a position himself to earn a livelihood but was living with his people at home who, he knew, would cut him off if he married without their consent. All his prospects were bound up with his people's goodwill towards him. Relations were consequently very strained at home: an uncomfortable restraint grew up between him and the rest of his family and every meeting with his fiancée had to be arranged by subterfuge.

A further factor which intensified the conflict was the strong love he had for his mother. Since his love difficulty he had had to repress his feelings for his mother—he must give it all, he said, to one or the other. And he had realised lately how much he owed his mother, how much she had sacrificed for her family. His duty towards her he conceived to be respect and love, but he felt that under the existing circumstances this was impossible. He was not sure, he said, if he was justified in continuing this attitude of suppression towards his mother; he felt that he was not doing what he ought to be doing. It implied that he would have to make a decision sooner or later unless he could lead a double life. This, in brief outline, was the substance of the conflict.

It is interesting to observe how the elements of conflict are expressed in the dream itself. L., of course, is his fiancée, manifested directly without symbolic concealment. The phrases, "Rushed past L.," "Was carried some distance (against my will)," "I felt that she was hurt with me and was half afraid to meet her, yet had a deep longing to meet her," very clearly indicate the conflicting impulses of his state of mind. The school he recognised to be one he used to pass every day when at home; the dream, the story or reproduction of his mental conflict, is given, in other words, in the first place its natural or realistic setting. The unknown town he realised at once to be Arras; he could see, he said, the wreckage and ruin about him. Arras had made a great impression on him. He was in the Arras sector when he broke down and had to be sent to hospital. It formed, in fact, a symbolical indication of the mental wreck he found himself as the result of the conflict. "She came down a narrow street to where I was standing." This led him through a series of associations to a street—a narrow street—in his home town and a block of flats there, the sort of flat, he said, he would choose as a home if he could afford it—an interpretation whose significance is sufficiently apparent. The analysis of the "man in khaki" brought out further factors of the conflict. He proved to be the girl's present employer, who, patient said he had reason to believe, was forcing his attention on her; he had read between the lines of her letters.

The investigation of this single dream supplied, it is evident, an illuminating insight into the patient's state of mind, and it furnished, further, the key to the solution of the "spotted pudding" obsession, the analysis of which had been left incomplete. The Italian woman, patient admitted, was his fiancée, L., and when the significance of the attribute Italian was investigated he stated that the foot-shaped contour of Italy brought him back to the preparatory school in which this had been first impressed on him. He remembered that at this school he had been punished by the teacher for something he was not guilty of, and the strong feelings of resentment and injustice he had felt had made an impression, he said, which remained to the present day. The Italian attribute expressed symbolically the feelings of resentment and injustice associated with the idea of L. against his people in their treatment of her.

As the nature of the condition was rendered clear it became evident that the symptoms expressive of war strain—the shakiness, loss of nerve under fire, &c.—were of minor importance in comparison with the mental conflict seen to be dependent on causes wholly antecedent to the war conditions.

The shock received from the explosion of the shell, by producing a common type of war neurosis based upon a different emotional pathology, had impaired the mental synthesis or "equilibration." It had thus created a condition of affairs predisposing to the development of the second neurosis, which till then had existed only in embryo. The former were, consequently, ignored in the further analysis of the condition as being capable of alleviation or cure only in conjunction with a removal of the deeper conflict.

The following day—the second after treatment had begun—he reported that the "spotted pudding" obsession had disappeared. It went gradually, he said. After he discovered the Italian woman she took the place for a time of the "spotted pudding," and now the Italian woman had also ceased to trouble him. Another obsession had taken their place and was constantly obtruding itself in the same way. It was the image of the sign-board that had been opposite the dug out he occupied at F —.

This obsession was accordingly analysed and the associations as they came up were as follows:—

"The colouring of the signboard impressed him (it was an advertisement for Michelin tyres)—yellow with a bright blue edging—the French flag—colouring appeared round the word 'F'—it changed from green to blue—became dark, almost black—the word 'F'—resolved itself into a golden line—two vertical lines appeared at the edges of it—they widened to the extent of the board—it appeared like a hansom cab seen from behind—the coachman with tall hat and cockade—it is a wedding—through the window at the back he sees a man and a woman kissing—". After some hesitation he admitted that it expressed his own wedding.

At the next interview, two days later, he reported that he felt considerably improved; his headaches were better and the obsessions had ceased to trouble him. From that time, as the analysis of the condition proceeded and one by one the various and complex factors of the conflict were brought to light, although from time to time he showed transient fluctuations, he made steady progress towards improvement.

On August 20th, 1917, that is after three weeks' treatment, he reported that the chief symptoms that remained were feelings of weakness and of effort in the attempt to do anything. The obsessive ideas had disappeared, he was free from the feeling of conflict and worry he used to have, and the paresthesias about the head had gone.

The condition as it unfolded itself became complex to a considerable degree. It would be impossible, therefore, within the scope of a short article to describe all the elements as they revealed themselves and brought to light the various aspects of the many-sided conflict. Two further dreams, however, are of some considerable interest. The first is as follows:—

I dreamt that as I lay in bed I suddenly realised the presence of a cat (dark colour) on my right shoulder. I stroked it and it commenced purring, whereupon I disposed of it (how I don't remember). Then another cat (also of dark colour) appeared in the same position, but it was not quite as tame as the former. Whether it disappeared or not I cannot say, as a small dark-brown, smooth-haired dog made its presence felt on myself. It had hypnotising bluish-green eyes (with large pupils) protruding from its head, and upon my attempt to soothe it (with the ultimate intention of throwing it out of the window or otherwise disposing of it) it bit into the palm of my left hand, and the pain caused me to wake up.

The patient had at this stage gained a certain proficiency in the art of analysing his own dreams, and he voluntarily produced the following interpretation. The cat, he said, seemed to typify his present condition, and the disposal of the cat seemed to mean that he had thrown off and got the better part of his mental trouble. The other cat typified a more difficult mental trouble yet to be got rid of. The dark colour signified his mental condition. The fact that the second cat was not so tame meant that this remaining difficulty was not so easy to get rid of as the former one.

Here his analysis ended; as regards the dog he could find no interpretation for it. Further investigation, however, brought to light its meaning. It was shown beyond doubt to be the symbolic representation of his fiancée, and "bit into the palm of my left hand" he interpreted as "something I want to get rid of pressing on my brain—something that binds me, holds me captive that I can't get rid of it." The condensation mechanism in regard to this symbol is shown in an instructive way in the fact of its being associated or "constellated" with two complexes of fear, one of which was the memory of an actual experience of being bitten by a

rat on one of the fingers of the left hand at the age of 5 or 6. The significance of this symbol in conjunction with the parenthetical phrase in the dream "with the ultimate intention of throwing it out of the window, or otherwise disposing of it," gives the first indication of the direction in which a solution of the conflict was shaping itself in his mind—an inference confirmed subsequently on the patient's own admission.

The remaining dream is not without its humorous aspect.

Someone (connected with the staff of this hospital) appeared and told me that Captain Dillon had committed suicide (as far as I can remember by means of a razor). I know that the scene where the dream took me was unfamiliar, but cannot recall details.

The "someone" on analysis proved to be my clerk, and the patient's immediate further association was that the clerk prepared all the base lists. He was wondering if he were going to be sent down to the base. Captain Dillon was the person who was at the time keeping him back. The unfamiliar scene he associated as "the roadway through the gate of the hospital—outside—freedom—Blighty." The dream, in short, expressed his desire to get to England. He had, in fact, a doubt as to whether he was being treated in order ultimately to be sent back to the line again. Captain Dillon formed the obstacle to his desire, and it is arranged that he conveniently puts himself out of the way.

The mechanism is well illustrated here of exaggeration or over-estimation of dream impulses by which difficulties or obstructing influences are removed not merely sufficiently for the purpose in view, but in an unnecessarily complete and extravagant way. This is well shown, too, in the dream of a patient who came to me in a very distressed state of mind because he dreamt that he had murdered his father. His father, it transpired, was a chronic invalid and a severe burden on the patient, who had a difficult struggle to keep his wife and children in decency. In the dream the unconscious took a thorough and effective method of disposing of the handicap, although consciously the patient had never entertained more than a passing and involuntary regret over the state of affairs.

Conclusion.

The treatment extended over a period of six weeks. Two days before being evacuated to the base the patient reported that the sense of fatigue had diminished, the feeling of restriction to consciousness had gone, and his power of concentration was returning.

The case illustrates in a striking way the great value of early treatment in disorders of this class, and shows that much may be done even under the conditions of an advanced centre in France. It forms a certain endorsement of the mechanisms of dream formation and of the principles in general of psycho-analysis. But, probably as important, it brings forward certain problems in the subject which are still awaiting settlement.

It will be noted, for instance, that all of the dreams in the case were not found to contain on analysis a sexual interpretation, as taught by Freud. My limited experience in this respect coincides with that of the schools of Jung and Adler in opposing the exclusively sexual interpretation. As regards, too, the question of a fixed symbolic meaning I am led to agree with Jung, who teaches that there are no fixed symbolic meanings to the images in dreams. "The various dream pictures have each their own peculiar value."

Another feature of the subject illustrated is the fact that while in some dreams the whole manifest content is "phantastic" in form, every element being disguised in symbolic figures, in others this is only partially the case, certain of the elements being used "realistically" in their everyday significance or value. To what extent the components of a dream are to be interpreted symbolically depends on the ultimate analysis of the dream as a whole.

In his conception of the "manysidedness" of dreams Jung has laid emphasis upon another aspect of dream formation of very great importance. "In view of the comprehensive many-sidedness of the dream material," he writes, "one must beware above all of one-sided formulations. The many-sidedness of the meaning of a dream, not its singleness of meaning, is of the utmost value, especially at the beginning of the psycho-analytic treatment." This is well shown in the first dream described above.

Finally, there is the problem raised by the nature of the conflict revealed in the analysis. We have had to deal here with a neurosis, the expression of a mental conflict dependent

inherently, not on early or infantile "fixations," but on a present and pressing difficulty urgently requiring removal. In a chapter in "Analytic Psychology" Jung discusses with Dr. Loy whether there are not certain moral problems in their nature incapable of solution. In the present case, analysis brought to light a conflict which was in large part unconscious, in which the opposing factors were unrecognised by or unknown to the patient. By this means the import and significance of the disrupting influences affecting his mind were made conscious and clear to him, the different elements as they appeared laid before him, as far as possible, in their true proportions. A new mental orientation was thus made possible for him, a new capacity given him to deal with the situation. Jung says: "Because (men) will not and cannot think out to its logical conclusion what it is they really desire, their erotic conflict is largely unconscious."⁶

The case, I am aware, affords opportunity for an exponent of the extremer school to maintain that if the analysis had been carried far enough the inevitable early sexual "fixation" would have been unearthed—perhaps in this instance in regard to the relation of the patient to his mother. It is not, of course, impossible, but as it can be neither verified nor disproved it has little practical bearing on the subject.

On the other hand, the disappearance of the obsessions and the improvement which resulted in the remaining symptoms are sufficient practical indication of the accurate direction of the treatment. An interesting epilogue is formed by a letter received from the patient a month after evacuation from the hospital, in which, after expressing his thanks for the treatment, he says: "I had very little faith in it until I realised that you had (1) analysed and thereby dispelled the obsessions I was troubled with; and (2) proved to me the mistaken attitude I had adopted towards certain matters."

Since the article was first written I have learned that the patient is now back at his former occupation.

THE PREVENTION AND TREATMENT OF DIABETIC COMA.

By P. J. CAMMIDGE, M.D. LOND.

OF all the complications of diabetes mellitus the commonest and most fatal is coma. In 50 to 60 per cent. of cases it is the immediate cause of death, and when once developed is usually fatal within a day or two, and sometimes within a few hours, of the onset of the characteristic symptoms.

Symptoms.

Coma may occur early or late in the course of the disease, although it is particularly prone to develop during the first year of treatment, and is more common under than over 40 years of age. The most striking symptom, exaggerated respiration without cyanosis or evidence of physical cause, often appears with dramatic suddenness. The respiratory movements change their character and gradually involve all the accessory muscles of respiration, inspiration is prolonged like the breath preceding a yawn, while expiration seems forced and more complete than normal, the so-called air-hunger of Kussmaul.¹ In the earlier stages the respiratory rate is not much accelerated, 16 to 20 a minute, but as the coma deepens it becomes more rapid and may reach 40 a minute, and there is then no evident pause between inspiration and expiration. A characteristic sweet, fruity odour of the breath, which may pervade the whole room, is noticed occasionally and will suggest to an experienced observer the cause of the coma. The face has an anxious expression and is sometimes flushed, although it is often pale and drawn, with a yellowish tint. The eyes are generally half closed, the pupils react to light until deep coma occurs and are usually dilated, less often contracted. Softening of the eyeball, due to a fall in the intraocular pressure, is an early and important sign of diabetic coma. The pulse is soft and accelerated, but rarely exceeds 120 a minute. The blood pressure is always low and

falls further as the coma develops. The usually subnormal temperature of a diabetic rises with the onset of coma and may reach 100° F. or thereabout, but as death approaches it sinks again and may fall as low as 90°. The extremities are cold and in some instances there is slight œdema of the feet.

Although coma may develop suddenly, particularly in the course of some intercurrent infectious disease, it is usually preceded by several days of suggestive symptoms, which point to the imminence of its occurrence. The appetite becomes capricious, digestive disturbances and slight nausea are complained of, weight is lost more rapidly than would be expected merely from defective nutrition, and cramp in the legs and abdomen occurs, particularly at night and the early morning. The patient becomes restless and irritable, and complains of headache, which is frequently attributable to the obstinate constipation which usually exists. Marked lassitude supervenes, and this is followed by drowsiness, which gradually deepens into profound coma from which the patient cannot be roused.

Coma of the type described is met with in many cases, but in some typical air-hunger is slight or absent and cardiac weakness dominates the picture. The patient may die suddenly with few warning symptoms, consciousness being retained to the end, or there may be a complaint of nausea or weakness, the pulse is found to be soft and rapid, 140 to 160 to the minute, the heart sounds are barely audible, and loss of consciousness is rapidly followed by death. In a few cases the onset of coma is ushered in by acute excitement and convulsions.

Indications of Commencing Acidosis.

Although the clinical symptoms of diabetic coma usually develop with startling suddenness, and the premonitory signs are often so slight or indefinite as to be easily overlooked, regular examinations of the urine, blood, and alveolar air furnish indications of the probable onset of the complication, so that if they are frequently carried out it should come as no unforeseen event. Ever since Stadelmann, in 1883, discovered oxybutyric acid in the urine in severe diabetes and compared diabetic coma with the condition produced in animals by poisoning with mineral acids, it has been recognised that diabetic coma is usually associated with a high degree of acidosis which, unlike the acidosis occurring in conditions where there is no disturbance of carbohydrate metabolism, is accompanied by the presence of acetone bodies in the urine.

The appearance of these bodies is usually the first sign of commencing acidosis. As the alkaline reserves of the body are lowered, through their being used for the neutralisation of the excessive formation of acids, the tolerance for sodium bicarbonate increases so that instead of 5 g. (77 gr. or 1½ dr.) given by the mouth, being lowered by the excretion of part in the urine, with a consequent change in the reaction to litmus from acid to alkaline as in normal persons, 75 to 100 g. (2½ to 3½ oz.) or more may be required in individuals on the borderland of coma. At the same time there is an increase in the ammonia output in the urine from the normal of 0.5 to 1.0 g. per day, up to as much as 10 or even 12 g. in cases of deep coma. As a rule an excretion of 4 g. a day rarely exists for more than a few days without coma developing. Normally the ammonia nitrogen constitutes 4 to 5 per cent. of the total nitrogen of the urine, but as coma becomes imminent 40 to 50 per cent. of the nitrogen may be excreted as ammonia.

A useful indication of serious acidosis is a diminution in the available carbonates circulating in the blood which may be determined indirectly, from a lowering of the carbon dioxide of the alveolar air, or directly from the blood itself. The carbon dioxide of the alveolar air can now be estimated at the bedside very easily and quickly by the simple and ingenious method devised by Marriott,² but for the analysis of the carbon dioxide content of the blood the more elaborate laboratory methods of Van Slyke³ are required. A diminution in the titratable alkalinity of the blood indicating an acidosis of clinical significance can be readily detected by the method described by Sellards,⁴ which depends upon the change in reaction to phenolphthalein from alkaline to

neutral of the protein-free filtrate of the serum when the alkali reserve of the body is definitely subnormal.

Criticism of Alkali Therapy.

Clinical experience and many laboratory experiments have suggested that diabetic coma is the culminating point of an increasing acidosis, and one might therefore expect that therapeutic measures to counteract and control the acidosis would prevent the onset of coma and cure it should it have developed. The obvious treatment would be to make good the alkaline reserves of the body and ensure their being maintained at the normal level by the administration of alkalis by the mouth or, if need be, by intravenous injection. It is true that a certain degree of success has apparently attended this method of treatment, and there are even a few cases of diabetic coma on record where large doses of sodium bicarbonate have saved the patient, at any rate temporarily, but on the whole the results of alkali therapy have been disappointing, and it can hardly be claimed that the death-rate has been materially improved by it. After all, it is only symptomatic treatment which does not touch the source of the trouble, the excessive formation of organic acids. Moreover, the attempt to control an acidosis with alkalis is not always free from danger and discomfort. Large doses of alkali, such as are often necessary, are apt to cause irritation of the gastro-intestinal tract and give rise to nausea and vomiting, especially if not administered in very dilute solution, and then the large amount of fluid may overburden the stomach and throw excessive work on the kidneys. When taken over long periods alkalis interfere with digestion, tend to deplete the body of necessary salts, particularly chlorides, and have a depressing effect on the heart if sodium salts are chiefly used. Finally, as Joslin has pointed out, it is possible that the administration of alkalis over long periods may set free acid bodies existing combined, quiescent, and harmless in the tissues, and so do harm, for the constant use of alkalis appears to promote the constant excretion of acid bodies. It is doubtful, therefore, whether the attempt to treat acidosis and prevent coma in diabetes with alkalis is sound practice, more especially as Allen's experiments⁵ have shown that in diabetic dogs no apparent prolongation of life results from keeping the alkaline reserve of the body normal with alkalis given intravenously or by the mouth.

Control of Fat Intake.

A more satisfactory way of attacking the problem would be to prevent the formation of unoxidised acid products by limiting the material from which they are derived, and this is quite a feasible proposition, for the work of Rosenfeld, Hirschfeld, Magnus Levy, and others have shown that fat is the chief source of the acetone bodies and that it is from the fat of the food they are mainly derived. Recent work has proved that careful control of the fat intake in the diet is one of the most certain practical methods at present at our disposal for preventing acid intoxication and subsequent coma. By this means Joslin,⁶ who was a pioneer in that aspect of the treatment of diabetes, has been able to reduce his death-rate through coma from an average of 64 per cent. to 44 per cent.

There seem to be two reasons why systematic control of the fat intake in diabetes has been hitherto neglected: (1) the very prevalent idea that diabetes is merely a defect of carbohydrate metabolism; and (2) the generally held doctrine that loss of weight by diabetics must be prevented at all cost. Experiments with diabetic animals and clinical observation have alike shown that both these ideas are erroneous. Diabetes is not a mere inability to assimilate glucose; from the first it is a defect in the metabolism of carbohydrate, protein, fat, and probably mineral substances as well, so that treatment directed to the control of the glycosuria alone deals with one aspect of the disease and overlooks what may be more serious but, for a time, less evident defects in the chemistry of the body. The treatment from the commencement must be based on the hypothesis that we have to deal with a general failure of metabolism, and that while restriction of a single food principle, such as carbohydrate, may suppress the symptoms temporarily the progress of the diabetic process can only be prevented and complications, including coma, avoided by dealing with the condition as a whole.

Fat being the principal source of the unoxidised acid end-products giving rise to acidosis, control of the fat in the diet of a diabetic is obviously a matter for serious consideration from that point of view alone, but it is also important from another aspect. It would seem that the weakened metabolic functions of the diabetic are capable of dealing with only a definitely limited load, and that when this load is exceeded failure of the metabolic processes occurs. Consequently, although a reduction of the carbohydrate in the diet may stop the glycosuria, it will not prevent the disease progressing if the total intake of food is maintained by adding fat or protein. The metabolic functions will then still be over-taxed, and in spite of an apparent improvement the glycosuria will eventually return with increasing acidosis, &c. For a time the progress of the disease may again be stayed by lowering the carbohydrate intake, but so long as the total load of food is not reduced the downward progress of the disease will continue. In other words, the case will have the characters of a progressive diabetes with a steady fall in carbohydrate tolerance, a type one so frequently meets, especially in young people where an attempt is being made to keep up the weight by over-feeding with fat and protein. If, on the other hand, such patients are allowed to lose weight until the body mass is reduced to a level that can be maintained by a total load of food below what can be efficiently dealt with by their defective metabolic powers the apparently inevitable progress of the disease is checked, return of the glycosuria is prevented, and acidosis is avoided, or at least kept within narrow limits. It is true that patients treated in this way become thin, but it does not follow that they are less efficient muscularly, for, as Williams's experiments have shown,⁷ and my own clinical experience confirms his results, muscular efficiency and weight are not synonymous. A thin patient feeding within his metabolic limits can do more, and is less easily tired, than one who is over-taxing his metabolic powers in an attempt to maintain a hypothetical weight for an individual of his size or who is over-weight.

Causation of the Coma.

Regulation of the fat intake in diabetes undoubtedly places in our hands a most useful weapon for combating acidosis, and it appears probable that the death-rate from coma may be materially reduced thereby, especially when control is exercised from the earlier stages of the disease, but it does not necessarily follow that no other methods are available to reduce still further a mortality which is appallingly high.

It has been for so long the custom to accept acidosis and coma as cause and effect in diabetes that the possibility of the acidosis being an associated, and perhaps an incidental, phenomenon has not received the attention it deserves. The failure of alkali therapy to achieve the results expected of it has been one of the main stumbling blocks in the way of a general acceptance of the acid intoxication theory, and it has therefore been suggested by some that the ketonic acids and their salts induce coma, not in virtue of their acid properties, as that theory assumes, but in consequence of some specific toxic action they possess. But experiment has proved that these substances are not poisonous to normal animals in doses likely to be met with in practice. To meet this difficulty it has been claimed⁸ that aceto-acetic acid and its salts are toxic if the animal is first rendered diabetic by extirpation of the pancreas. I am not prepared to deny that a diabetic and a normal animal may react differently to these substances, and that they may be more poisonous to the former than to the latter, but the fact that a condition which is known to alter fundamentally the metabolism of the body, and of itself leads to coma, has to be instituted before reasonable doses produce a toxic effect rather tends to weaken the force of the argument.

There can be no doubt that coma is the consequence of an auto-intoxication, but consideration of the evidence available suggests that it is a toxæmia resulting rather from the general failure of metabolism occurring in diabetes than from a specific toxin originating in a break in the chemistry of the body in one particular direction. It seems most likely that coma may be produced by several toxins of different origin acting together. In some instances, however,

the metabolic defect may be more complete or rapid in one direction than another, and occasionally there may be associated defects in excretion, such as we know to occur in interstitial nephritis, which will cause one type of poison to have a preponderating effect. In this way we can account for the variations in the symptoms met with in different cases and for the occasional beneficial effects of the alkaline treatment.

Possible sources of toxins, other than fat, are carbohydrate and protein, while the modifying influence of inorganic salts on metabolism must also be taken into account. It is unlikely that carbohydrates give rise to poisonous materials that tend to produce coma directly, for experience has shown that increase in the carbohydrate content of the diet when coma threatens often brings about a temporary improvement, especially when the patient has been treated previously on the historic lines of a "carbohydrate-free" diet, consisting chiefly of protein and fat. Indirectly an excess of carbohydrate in the diet, no doubt, has an influence in causing this complication, first through its effect in accentuating the metabolic deficiencies which underlie the diabetic condition, and secondly through the dehydration of the tissues consequent on the presence of an excess of sugar in the circulation. Water is needed to maintain the volume of the blood required for the mechanical efficiency of the circulatory apparatus, to carry nourishment to the cells, to remove the waste products of metabolism in solution, and to maintain the osmotic conditions essential for cell life. When it is abstracted from the body, and the loss is not made good owing to conditions of the gastro-intestinal tract which prevent retention and absorption, acidosis, sudden large inflammatory exudates, and other reasons, serious and rapid loss of weight occurs, the respirations and pulse increase in frequency, the systolic blood pressure falls, the tension of the eyeball is markedly diminished, the tongue becomes dry and parched, there is oliguria with constipation, the patient becomes restless and irritable, then apathetic, and, finally, comatose. The similarity of these symptoms to many of those met with during the onset of diabetic coma suggests that some of the latter, at least, may be a consequence of the dehydration of the tissues produced by a high concentration of sugar in the blood. It also helps to explain the frequency with which coma is precipitated by gastro-intestinal disturbances, particularly when there is vomiting or diarrhoea, and by conditions where large inflammatory exudates take place.

Disturbances of Protein Metabolism.

In 1913 Pribram and Loewy⁹ suggested that abnormal products of protein cleavage might be responsible for part of the symptomatology of diabetic coma. Other authors have since claimed that death in some cases may be entirely due to the effect of toxins resulting from the imperfect metabolism of proteins, and quoted cases of fatal coma where no evidence of acidosis existed.¹⁰ The occurrence of such cases, the absence of typical air-hunger in many instances, and the failure of alkali therapy to control the coma in most cases favour the argument that the condition does not always, or entirely, depend upon the acid products of defective fat metabolism and lend support to the view that other toxins are involved.

It has been shown experimentally that some of the products of protein disintegration are toxic, producing among other symptoms lowering of the blood pressure, depression, and narcosis, but no attempt appears to have been made to isolate such substances in diabetes. Some experiments I commenced four or five years ago with that end in view had to be abandoned temporarily, but so far as they went, and taken in conjunction with the results of the routine analysis of the urine in a large number of cases, they showed that protein metabolism in diabetes tends to become less and less complete as the disease advances, and that this is associated with a progressive failure in the functions of the liver similar to what is met with in acute yellow atrophy, some of the toxemias of pregnancy, &c. One of the most striking features of the urine in all severe cases of diabetes is the constant presence of amino-acids, which increase in amount as the disease advances, so that the amino-acid nitrogen often constitutes 50 per cent. or more of the total "ammonia nitrogen" as estimated by

the Malfutti formalin process. In one instance, for example, I found 6.3 g. of amino-acid nitrogen out of a total of 7.8 g. of "total ammonia nitrogen" in a 24 hours' specimen of urine passed six days before death from coma took place. In three cases where an analysis of the collected 24 hours' urine was made shortly after the premonitory symptoms of coma had appeared the amino-acid nitrogen was found to have dropped suddenly and in one had entirely disappeared, although 4.3 g. had been present the previous week. The nature of the amino-acids was investigated in 11 cases, three of which eventually died of coma. Tyrosin, histidin, phenyl-alanin, and glycocholl were found in all, while tryptophan, alanin, leucin, and arginin were only met with in the more advanced. In two cases, both of which died shortly after of coma, an amine resembling in some respects a toxic base described by Dale and Laidlaw¹¹ was isolated. Very often a marked increase in the uric acid output, which may reach 8 or 9 g. a day, is seen at, or about, the same time as the rise in the amino-acid nitrogen occurs and without any change in the diet being made. As a rule, the curves of excretion of uric acid and creatinin tend to run in opposite directions in diabetes and the rise in the uric acid preceding the onset of the symptoms of coma is no exception, a corresponding fall in the creatinin output usually being seen. Simultaneously the excretion of urobilin in the urine increases. These observations point to the onset of coma being associated with a failure in the functional activity of the liver, and it seems likely that the resulting imperfections in protein metabolism may be a contributory factor at least in bringing about the condition.

Effect of Withdrawal of Bases from the Tissues.

In a previous paper¹² I considered the effect of the withdrawal of bases from the tissues resulting from acidosis, and particularly of calcium and magnesium. I there pointed out that a balance between the two appears to be necessary for the smooth and efficient working of the nervous system and that an excessive loss of magnesium is associated with nervous instability. A striking increase in the magnesium and calcium loss in the urine is a constant feature of all severe cases of diabetes, and it is not unlikely that this loss renders the nervous system more susceptible to the action of toxins formed in the liver and elsewhere. The experiments of Osborne, Mendel, and Ferry lend support to this view, for they found that rats fed on a diet poor in inorganic salts, but otherwise satisfactory, eventually developed coma, and that they could be resuscitated by the administration of a mixture containing calcium and potassium phosphate, sodium chloride, and citrates of sodium, iron, calcium, and magnesium.¹³

Preventive Treatment.

If, as the foregoing considerations suggest, diabetic coma is not due to one cause, but is a complication arising from the cumulative effects of several, which result from the general metabolic failure of the diabetic organism, it is clear that treatment directed to one cause is not likely to control the symptoms, at any rate, more than temporarily, and that the only "cure" is to prevent all possible causes by so arranging the diet that (1) the patient's tolerance for carbohydrate, protein, and fat is not exceeded; (2) the total load of food is within his metabolic capacity; (3) the diet is correctly balanced; and (4) a sufficient allowance of inorganic salts is provided. Obviously the earlier in the course of the disease such treatment is commenced the better are the results likely to be and the less difficult will it prove to arrange a diet fulfilling the necessary conditions, but even with advanced cases a surprising improvement can be effected by careful dieting along these lines.

When a diabetic patient is first seen no change should be made in the character of his food. If possible he should be kept for a few days on an ordinary mixed diet of known composition and the opportunity taken to investigate his metabolism by analyses of the urine, blood, &c. The effect of excluding fat from the diet should then be tried. After a day or two on a fat-free diet the protein may be reduced by half. Subsequently the carbohydrate allowance may also be halved, then the remainder of the protein excluded, and the carbohydrate further reduced until a diet of green vegetables of low carbohydrate value only is being taken. If

sugar is still being excreted in the urine or the blood sugar is high and serious acidosis or evidence of abnormal tissue waste persist, two or three days' "starvation" may be prescribed, but longer continuous fasts are best avoided. Abstinence from food usually has a remarkable effect, improving carbohydrate tolerance, correcting errors in protein metabolism, and reducing acidosis, so that patients apparently in a grave condition may often be rescued and put on a metabolic basis that permits of a satisfactory diet being subsequently constructed.

The building up of the diet must be gradual and be carried out in the reverse order to that outlined above—that is to say, green vegetables alone, with a gradually increasing carbohydrate content, should be allowed first, then a very limited amount of fat-free protein, such as boiled white fish or chicken, is added, more carbohydrate is next given, and later the protein is increased until the patient is in nitrogenous equilibrium. When this point is reached fat may be allowed, at first in small quantities and later in larger amounts, but the effect on protein metabolism and the utilisation of carbohydrate must be carefully watched by regular examinations of the urine and blood. It is necessary that part of the carbohydrate should continue to be taken in the form of green vegetables, the exact proportion varying according to the patient's tolerance for starchy foods. It is also an advantage if at least one serving of raw vegetable (e.g., as salad) is eaten each day. These precautions not only help to overcome the constipation from which most diabetics suffer, but also ensure a sufficient supply of the inorganic bases that are essential for proper metabolism and render the medicinal use of alkalis unnecessary.

No attempt should be made to work the diet up to a theoretical caloric content based upon the size of the individual. If this can be done without risk so much the better, but the future progress of the case should not be sacrificed for a merely temporary benefit. The diet must be arranged to suit the patient's present metabolic capacity, not his appetite; in other words, he must be taught "to eat in order to live, not live to eat." The cardinal and very common mistake of an unbalanced diet should be carefully avoided. The effect of an excess of carbohydrate soon shows itself in the urine and is easy to recognise, but the equally deleterious results of too much protein or fat are not at once so evident. The best guide to the protein limit is the nitrogen balance, and the protein allowance should be so arranged that its nitrogen content does not exceed the daily total nitrogen output in the urine by more than 1 or 2 g. So long as this ratio exists further trouble from disturbances of protein metabolism need not be feared. Fat, unbalanced by other foods, is an insidious poison for the diabetic, and every endeavour should therefore be made to keep the fat allowance at a level corresponding to the patient's capacity for dealing efficiently with other foods. For practical purposes it may be taken that the allowance of fat, at least in the earlier stages of treatment, should not exceed the allowance of carbohydrate, or at most not be more than half as much again. A higher proportion is likely to lead to subsequent difficulties, and these are certain to occur if the proportion of fat to carbohydrate is more than 4 to 1. Determination of the fat content of the blood is undoubtedly the best guide for ascertaining the optimum allowance of fat in the diet, but regular estimations of the percentage of sugar in the blood also give useful indications, for a steady increase, especially if not associated with glycosuria, suggests that too much fat is being taken.

I have recently had under my care a patient, sent to me by Sir John Tweedy owing to an eye trouble associated with diabetes, who illustrated this point very well. When I first saw him his blood sugar stood at 0.20 per cent. and he was passing 15 g. of sugar a day in his urine. After a week of treatment the glycosuria had disappeared and his blood sugar had dropped to 0.08 per cent. A week later on a diet containing 50 g. of carbohydrate and 70 g. of protein, but practically no fat, the blood sugar had risen to 0.11 per cent. He was then given fat in gradually increasing amounts up to 60 g., when it was found that the blood sugar had risen to 0.18 per cent., although there was no sugar in the urine. On dropping the fat to 10 g. but not otherwise altering the diet, the blood sugar came down to 0.11 per cent. again. A return to the previous allowance of fat was followed by a rise in the blood sugar to 0.18 per cent., but still without glycosuria.

Treatment of Cases with Coma.

So long as the exact cause of diabetic coma remains obscure preventive treatment based upon a system of dieting calculated to stay the progress of the disease as a whole is the most certain means for eliminating this, and other, complications. It sometimes happens, however, that a patient is not seen until coma has developed or its onset is imminent. Under these circumstances he should be put to bed and be kept warm with suitable clothing, hot bottles, &c. All disturbing influences should be avoided and absolute rest and quiet be insisted on. The bowels should be thoroughly cleared by one or two large enemata. If there is a history of constipation a small pill containing bile-salts, calomel, and pil. rhei co., or colocynth and hyoscyamus, may be given and repeated if necessary, but excessive purgation with the risk of subsequent diarrhoea must be avoided. Gastric lavage, if practicable, may help to eliminate toxins. Whatever diet has been taken previously it should be stopped and replaced by 2 oz. of lemon juice, and either 7 to 8 oz. of potato or $2\frac{1}{2}$ to 3 oz. of oatmeal, taken in the form of thin purée or gruel in small quantities at 3 or 4 hourly intervals over the 24 hours. If possible the starch should be dextrinised by steaming the potato for 3 to 4 hours and gently boiling the oatmeal for 5 to 6 hours. After 24 to 48 hours even this small amount of carbohydrate may be omitted for a day or two. From the first the patient should be encouraged to drink as much liquid as possible, preferably in the form of hot water, weak tea or coffee, thin broth, &c., a minimum total of 5 to 6 pints, distributed evenly over the 24 hours, being aimed at. Should so much fluid be refused, or if there is a tendency to vomiting, the balance should be administered as normal saline per rectum, or, if need be, intravenously. Intravenous injection should not be too long delayed, as there is much more hope of its being beneficial during the premonitory stage than when coma has actually developed.

It has been the custom to give large doses of alkali in coma and threatened coma, but lately Joslin has claimed that better results can be obtained if alkalis are avoided altogether and simple salt solution, or even tap water, is used for injections. According to him, if alkalis have been given previously they should be omitted at the rate of 10 g. a day. There are some cases which are undoubtedly benefited by alkali therapy, however, particularly those where there is a uræmic element in the condition, and I therefore think that if speedy improvement does not follow the measures outlined above alkaline injections should be tried. Small uncontrolled doses are useless, the only method likely to be of much avail is to employ massive doses and regulate their administration by repeated examinations of the blood by Sellards's method or by estimations of the carbon dioxide content of the alveolar air. The injections should be continued until it is clear that any acidosis, whether due to the diabetic condition or to uræmia, has been neutralised by a return to normal of the titratable alkalinity of the blood or of the carbon dioxide content of the alveolar air. The copious diuresis that follows large intravenous injections will tend to eliminate other toxins, and bleeding from the opened vein to the extent of 10 or 20 ounces will also help in that direction.

Bicarbonate of soda is the alkali usually employed for intravenous injection, although some have advocated the use of the normal carbonate, on the ground that it has a greater neutralising power; but this advantage is more theoretical than real, for while it is true that weight for weight the carbonate can neutralise more than one and a half times as much acid as the bicarbonate, the latter can be used with safety in so much stronger solution that the difference is more than counterbalanced. Observation has shown that an average adult possesses not much more than 200 g. of sodium bicarbonate, or its equivalent, in a form available for the function of respiration, and that with a deficit of 150 g. or more air-hunger and coma develop. We may therefore assume that in most cases of coma a dose of bicarbonate of soda approaching 150 to 200 g. (5 to 7 oz.) will most likely be required. It would obviously be dangerous to introduce this amount into the circulation at one dose, and the maximum that should be attempted is 50 to 60 g., in the form of a litre of a 5 to 6 per cent. solution, or $1\frac{1}{2}$ oz. of sodium bicarbonate in 30 oz. of water. The solution should be sterilised if possible, but precautions should be taken to prevent the formation of the caustic normal carbonate,

which readily occurs on boiling. If the bicarbonate solution is filled into strong narrow-necked bottles, with tightly-fitting stoppers tied in place so as to reduce the air-space to a minimum, this danger is very largely avoided, and to make sure a stream of carbon dioxide gas may be bubbled through the solution after it has cooled. In an emergency unsterilised tap-water may be used without serious risk. The solution should be injected by the gravity method very slowly, half to one hour being allowed for a litre, and it should be kept at or about the temperature of the body. It is usually necessary to repeat the injection in about six hours, and if need be it may be repeated again after 12 and 18 hours.

Cardiac stimulants are advisable at an early stage in all cases of coma or threatened coma. Digitalis, subcutaneously or by the mouth, is probably the best, but strychnine, caffeine, alcohol, ether, camphor, ammonia, and pituitary extract may also be useful. There is a natural disposition to administer oxygen to relieve the distressing symptoms of air-hunger, but it is a useless procedure, excepting for the mental effect on those who are watching, for the difficulty in respiration has been proved not to be due to lack of oxygen.

Clinical Notes :

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON THE FORMATION OF OTHER AGGLUTININS IN CASES OF MALTA FEVER.

BY L. T. BURRA, M.D. OXON.,
LATE TEMPORARY CAPTAIN, R.A.M.C.

THIS note was written with a view to its publication in June, 1916, when the work was cut short by my transfer from Malta to Egypt, but owing to circumstances which arose at that time permission to publish it was withheld. I am indebted to Colonel A. C. O'Sullivan, A.M.S., for his permission to publish it, which was granted at a later date, and of which I now avail myself.

In the course of routine examinations of patients' sera in the laboratory of the Military Hospital, Imtarfa, Malta, I noticed that in cases of Malta fever agglutinins for the *Vibrio cholera* appeared, although, according to their histories, the patients had not been inoculated against cholera and had no symptoms of cholera. I have not been able to collect sufficient cases to state that in cases of Malta fever there is always the power to agglutinate a cholera emulsion, but the occurrence of this phenomenon in six cases is perhaps sufficient justification for drawing attention to it in this note.

The routine examinations of sera for agglutinins were made on slides by the rapid macroscopic method, using dilutions of serum from 1 in 10 upwards and emulsions in normal saline of dead and washed bacteria. In three cases the sera were put up in a series of dilutions in Wassermann tubes in the usual way, and were examined after 24 hours at the laboratory temperature.

The results of my observations were that in all six cases both *M. melitensis* and *V. cholera* were agglutinated. In one case the serum when first examined agglutinated the former only; two weeks later there was feeble cholera agglutination as well, while six weeks after the first examination this serum agglutinated *M. melitensis* up to 1 in 1600 and *V. cholera* up to 1 in 200. In those cases in which I had enough serum I added to a 1 in 5 dilution of the serum an equal quantity of the emulsions of *M. melitensis* and *V. cholera* in separate tubes, examining the serum for agglutinins after 24 hours at laboratory temperature. In every case saturation with *M. melitensis* emulsion removed the power of agglutinating cholera; and in the four cases in which the serum was saturated with cholera emulsion it retained its power of agglutinating *M. melitensis*.

I am indebted to Professor Zammit for the sera of three goats which were known to be infected with *M. melitensis*, which I examined on the same lines as the human sera. All of these sera agglutinated *V. cholera* as well as *M. melitensis*, and after saturation with *M. melitensis* emulsion this power of agglutinating *V. cholera* was removed.

In no case was the serum heated, and in none of the patients was the *M. melitensis* grown from the blood, so that the evidence of *M. melitensis* infection may be considered insufficient. The point, however, may be of interest to those who have the material for further investigation, and for this reason I draw attention to it. In conclusion, I wish to express my thanks to Professor Zammit and to Surgeon Lynch, R.N., who kindly provided me with some of my material; and to Captain W. B. Alcock and Captain N. Campbell, R.A.M.C., for their advice and suggestions as to the tests which I have made.

Aylesbury.

A CASE OF ASPIRIN POISONING.

BY F. W. LEWIS, M.R.C.S., L.R.C.P.,
ACTING MAJOR, R.A.M.C. (T.).

IN view of the promiscuous way in which aspirin, often self prescribed, is taken by the general public, the following case is of considerable interest to the profession.

Patient, sergeant, U.S.A., aged 24, was admitted to the Theford Military Hospital on Oct. 25th, 1918, with the history of having been taken ill two days previously with influenza. He was a powerfully built man and gave no history of previous gastric or intestinal trouble. He stated that he had been taking aspirin capsules of his own in addition to 18 5-gr. tablets given to him by the medical orderly. Instead of keeping to the prescribed dose, he had taken them all, together with a number of capsules in the course of six hours. He did this in order to get fit quickly, as he was under instructions for France.

On admission patient was markedly anæmic, temperature 101.4° F., pulse 120. During the day he vomited undigested milk, with no trace of blood. On Oct. 26th the anæmia was more profound. Pulse 150—weak and irregular. An enema was administered with little result. The vomiting continued at intervals. On the following morning, at 5 A.M., a large quantity of blood was passed by the bowel and he rapidly became unconscious. No thought of an exploratory laparotomy could be entertained. He died a few hours later.

Post-mortem.—There was no peritonitis, and no free fluid in the abdominal cavity. The last 5 feet of the ileum was acutely congested, and the cæcum and colon were loaded with blood clots. The line of demarcation between healthy and congested bowel was very definite. On opening the small intestine it was found to be uniformly inflamed. The mucous coat had apparently disappeared, leaving the sub-mucous coat and blood-vessels exposed and eroded. Bleeding from this large area had evidently been the cause of death. The other organs were in a healthy condition.

Remarks.—Aceto-salicylic acid is known to pass unchanged through the stomach and upper portion of the small intestine, and is then converted into free salicylic acid. It is probable that this man took nearly 200 gr. of the drug into an empty alimentary canal, and that the salicylic acid formed was responsible for the removal of the whole lining membrane of the bowel in the area described. The mucous membrane of the cæcum and colon appeared to be unaffected. An inquest was held and a verdict of "Death by misadventure through an overdose of aspirin" was returned. It would be interesting to know if this possible action of large quantities of salicylic acid on the bowel is recognised, or if this case may have been due to some impurity in the aspirin.

A CASE OF STRANGULATED FEMORAL HERNIA.

BY STEPHEN M. LAWRENCE, M.D., B.S. LOND.,
M.R.C.S., L.R.C.P.,

ASSISTANT SURGEON, GRAVESEND GENERAL HOSPITAL; SURGEON, YACHT CLUB, V.A.D. HOSPITAL.

THE following case of strangulated femoral hernia seems worth recording, partly because it is unusual for such a condition to come under treatment so late and partly because several mistakes were made in the treatment, and by these mistakes it is hoped that something may be learnt.

The patient, aged 47, is the mother of nine children. She sent for her doctor on Nov. 27th, 1917, who diagnosed a strangulated femoral hernia which had existed for four days. She had been in great pain all this time, had vomited continually, and had passed no flatus, but she had not kept in bed.

First operation (Nov. 27th, 1917).—On opening the sac it was found full of offensive pus and a knuckle of gangrenous bowel, about 2 inches long, which was giving way at the

neck of the sac. The same incision was extended upwards and outwards, the deep epigastric vessels ligatured, Poupart's ligament divided, and the peritoneum opened, thus exposing well the whole damaged bowel without pulling on or in any way disturbing the parts. The strangulation was about 5 feet above the cæcum. About 5 inches of the gut were removed. An attempt was then made to get the cut ends delivered out of the wound for an anastomosis. But the mesentery was so oedematous, congested, and friable, that any further handling caused tearing and bleeding, and, what was worse, stripping of bowel from mesentery. After wasting much time in this attempt and arresting hæmorrhage, another three or four inches had to be resected where it had stripped from the mesentery, and, finally (what should have been done in the first instance) a Paul's tube was tied into the proximal gut. This was anchored to the lower end of the incision (i.e., the femoral ring) and the distal gut anchored to the very top of the incision. The patient stood the operation better than I expected. The Paul's tube held for three days. The superficial part of the wound suppurated and prevented further operation for seven weeks. In the meantime the patient lost much flesh although she took food well, and in spite of opium and bismuth, which were exhibited to delay peristalsis.

Second operation (Jan. 16th, 1918).—A vertical incision was made just to the right of the middle line. Towels were clamped to the edge of the wound by Van Houzel and Backhaus forceps. On opening the peritoneum it was difficult to identify the parts because of adhesions, which considerably delayed the operation. The distal portion of the bowel, which had shrunk to very small dimensions, was then divided at (a), about 3 inches from where it was anchored to the skin (b), and both ends closed. A lateral anastomosis was then made to the proximal gut at (c), about

8 inches from where the latter was anchored to the femoral ring (d). The distal gut was so small and the proximal so large that, fearing symptoms of obstruction, the division of the latter at (c) was left for the subsequent operation. I thought that by plugging the orifice at (d) the faeces could be induced to go entirely along their new channel, and that possibly a third operation might not be necessary. This was undoubtedly a mistake.

The patient suffered no shock from the operation, but had severe enteric bronchitis with a marked rise of temperature. After 14 days, by the aid of enemata, about half the fæces appeared in the stools. After that the amount in the stools steadily declined. Plugging the orifice was useless. The plug was forcibly ejected after much pain. Saline aperients, which the pharmacologists tell us act chiefly on the lower bowel, were tried, but only increased the amount on the dressings. The patient's skin got very bad. She became emaciated, listless, and depressed.

Third operation (Feb. 18th, 1918).—The abdomen was opened through the scar of the last operation, much care being taken to shut off the skin, which was very swollen and eczematous from being in constant contact with faeces. This operation proved the most difficult of the three on account of the massive adhesions. It was impossible to identify the piece of bowel for severing except by pushing a long instrument into it through the opening at (d) and feeling for the end inside the abdomen. It was divided about 5 inches from its opening on the surface. The end of the bowel was then closed—silk for the mucous membrane and catgut Lembert sutures for the peritoneal surface. I used catgut because I feared a possible stitch sinus. But the catgut must have

slipped and faeces in abundance appeared in the wound on the third day. The mesentery of the detached piece of bowel (c-d) was next ligatured and divided. This piece of gut was then forcibly dragged out of the wound, leaving a large hole at the site of the femoral ring, admirable for draining. The central wound was then closed and a drainage tube placed in the old femoral ring. The patient was so well after the operation that on the third day I risked ordering an enema. This was most disastrous. Faeces again appeared in the wound and I thought I had lost my patient. However, this was the only time we saw them. From that time on she never looked back again. Liquid paraffin was the aperient used on all occasions.

The little portion of bowel (a-l) has never been detached, and when she left the hospital it formed a small sinus 3 inches long, occasionally discharging a little mucus. Subsequently this has quite dried up. No special measures were taken to repair her femoral ring and yet there is no hernia now. Considerable praise is due to the sister in charge of the case for not infecting the central incision after the second operation. The patient cooperated well, too, telling the nurse directly she was soiled.

She is now at her work again and feels no abdominal discomfort, and has even discontinued her liquid paraffin, which was such a stand-by earlier. She consulted me about two months ago because she thought she was pregnant.

Reviews and Notices of Books.

The Operative Treatment of Chronic Intestinal Stasis. By Sir W. ARBUTHNOT LANE, Bart., C.B., Consulting Surgeon to Guy's Hospital and to the Hospital for Sick Children, Great Ormond-street. Fourth edition, revised and enlarged. London: Henry Frowde and Hodder and Stoughton. 1918. Pp. 328. 20s. net.

EVERYONE who has devoted any attention to the matter must recognise that to Sir Arbuthnot Lane we owe in great part the increased attention now given to the dangers attendant on the too prolonged retention of faecal matter in the bowel. He it was who first drew attention to the risks of absorption from the intestine of the products of the activity of colon bacilli and of other micro-organisms; and it was he who first laid stress on the importance of kinks in the bowel produced by adhesions as the causes of intestinal stasis. And so clearly has he put forth his facts and his inferences, so carefully has he marshalled the data on which he founded his theories, that now those who accept his conclusions are continually increasing in number, and yearly more and more surgeons base their practice on his teachings. We do not say that Sir Arbuthnot Lane may not have pushed his theories too far; he may have thought that their application was wider than it really is, but even allowing for the over-enthusiasm of the discoverer there can be no doubt that he has brought to our notice facts that were almost unknown or ignored before, that he has pointed out a potent cause of much chronic ill-health, and that he has indicated the direction which treatment must take if these evils are to be overcome.

This book is not the unaided work of Sir Arbuthnot Lane, for he has many coadjutors. Dr. Alfred Jordan has contributed a most important chapter on the investigation of chronic intestinal stasis by means of the X rays; he shows the immense value of the additional information that may be obtained by the use of this method, so that the surgeon shall be in a position to act with the best effect when the abdomen is opened. Dr. Nathan Mutch has supplied a short but valuable chapter on the bacterio-chemistry of the small intestine and a much longer chapter on chronic streptococcal infection. Professor Arthur Keith has written on the great bowel from the anatomist's point of view, and Professor J. G. Adami has furnished a chapter on intestinal stasis and intoxication. The relation of intestinal toxæmia to loss of accommodative power has been explained by Mr. Ernest Clarke, and Dr. Leonard Williams insists on its importance from the medical standpoint. Major White Robertson has described the blood picture of this condition, and Mr. Harold Chapple has written on the gynecological aspect of the stasis. The connexion of pyorrhæa with stasis in the bowel has been pointed out by Mr. Harry Forsyth. It will thus be seen that Sir Arbuthnot Lane and his collaborators have traversed the whole field of intestinal stasis; they have collected together a vast corpus of information all bearing on the subject, and the reader cannot fail

to acknowledge that there is a large amount of truth in the claim that intestinal stasis is a potent factor in disease, and that the prevention and removal of the stasis is of vital importance. The veriest sceptic, if indeed there be any such, cannot rise from the perusal of this volume without recognising that the matter deserves the closest study. To all medical men we commend this book, for it gives a full and faithful presentation of this important subject.

A System of Clinical Medicine. By THOMAS DIXON SAVILL, M.D. Lond. Fifth edition, thoroughly revised. London: Edward Arnold, 1918. Pp. 948. 28s. net.

THE issue of a fifth edition of Savill's *System of Medicine* is surely an evidence of its increasing popularity. The fourth edition was issued in 1914, and reprinted in 1916. The present edition has been thoroughly revised, notably the chapter on diseases of the nervous system by Dr. Harry Campbell, and some of the sections, such as those dealing with diabetes mellitus and syphilis, have been entirely rewritten. There are many additions, amongst which may be mentioned spirochaetosis ictero-haemorrhagica, purulent bronchitis, and trench fever. So much for a short account of the more important changes in the new edition which may be of interest to those who are already acquainted with the work. To the less fortunate we may give a short description of Dr. Savill's method of dealing with the study of disease, or rather with the study of disease as manifested by any one particular patient, for this text-book is essentially clinical in its outlook. The author does not describe each disease separately, as is usually done in text-books, but the order of sequence is, as he says, that which "should be adopted in the examination of the patient," the principle throughout being to trace "from effect (symptoms) to cause (the morbid cause in operation)." To quote the author again: "Each chapter is divided into three parts. Part A treats of the *symptoms* which may indicate disease of the organ or region under discussion, the fallacies incidental to their detection, and gives a brief differential account of the various causes which may give rise to those symptoms. Part B treats of the physical signs of disease in that organ and the various methods used to elicit them. Part C, which constitutes the major portion of each chapter, is prefaced with a *clinical classification* of the various maladies affecting that region and a summary of the routine procedure to be adopted; this is followed by a series of sections dealing with the several *diseases* arranged according to their clinical relationships. For example, in Chapter III., on the heart, Part A describes and differentiates the various causes of breathlessness, dropsy, palpitation, præcordial pain, and the other symptoms which may be indicative of heart disease; Part B describes percussion, auscultation, and other methods of examining the heart; and Part C deals *seriatim* with the various cardiac disorders, classified and arranged on a clinical basis." To the busy practitioner the utility of such a work is obvious; in a difficult case he has but to turn to the chapter dealing with the affected region, and he finds at once a simple method of differential diagnosis. But the work is especially helpful to the student newly arrived at that stage in his curriculum when he is faced with the problem of a particular patient and is obliged to carry out his examination and make his diagnosis on its result. This text-book will help him on from stage to stage, and if in the end the diagnosis is still in doubt he will have learned how to observe accurately, how to reason clearly and correctly, and by balancing the evidence will at least be able to understand the possible diagnoses which his teacher will discuss in due course.

The Australian Army Medical Corps in Egypt in 1914-15. By Sir J. W. BARRETT, K.B.E., M.D., F.R.C.S., Temp. Lieutenant-Colonel, R.A.M.C., and Lieutenant P. E. DEANE, A.A.M.C. Illustrated. London: H. K. Lewis and Co., Ltd. 1918. Pp. 259. 12s. 6d. net.

THIS book is very much of the nature of an expanded report on the working of No. 1 Australian General Hospital at Cairo and the Australian Branch of the British Red Cross Society. Sir James Barrett combined the duties of consulting oculist and aurist and registrar of the hospital, and executive officer of the Australian Branch of the Red Cross Society; Lieutenant Deane was quartermaster to the hospital. The presence of this Australian Hospital in Egypt was especially fortunate on account of the

sudden influx of wounded from the Dardanelles, which necessitated the expansion of the hospital from one of 520 beds to a group of hospitals providing accommodation for 10,500 patients. The story of the expansion is interestingly told, although perhaps the experience is not so unique as the authors imagine; very much the same difficult course of events occurred at Alexandria where the problem was tackled by the R.A.M.C. The book brings up all the various problems which have beset our armies elsewhere—the recruitment of the unfit, the drink problem, the venereal diseases problem. We are in debt to the authors for their frank account of events; their extensive experience of the methods tried to prevent venereal disease lends weight to their criticism of the new constitution of the Australian Red Cross Society, which does not allow of the spending of money for the maintenance of social clubs for soldiers:—"Why not supply for the benefit of the men places of entertainment, with music, refreshments, and the like, similar to, and better than, those which the prostitutes supplied, but minus the prostitute?" The whole-hearted co-operation of the Australian medical forces with our own and the French is incidentally revealed; Australia in the early days in Egypt provided motor transport for the whole of the wounded and gave away 75 per cent. of their Red Cross stores to hospitals for British or French troops. Over 100 pages of the book are given up to a detailed account of the work and criticism of the functions of the Australian Branch of the Red Cross Society in Egypt. The numerous photographs illustrating the book are exceptionally good; the three maps included are useful. The book is apparently intended for the Australian lay public; although it is not a contribution to the study of Egyptian medicine it will be read with much interest by every medical man who has served in Egypt.

JOURNALS.

Revista Española de Medicina y Cirugía. Provenza 273. Barcelona. Pp. 50. 2 ptas.—We have received the November issue of this review, being the fifth monthly number since its first publication in 1918 at Barcelona under the editorship of Dr. Francisco Tous Biaggi. It seems to us a practical and up-to-date addition to medical literature, such as is wanted not only in Spain but in other countries. This number contains an article on Technique in Microscope Work by Dr. Pujula, in which he explains his methods of staining sections of nervous tissue by nitrate of silver and Kopsch's bichromic formol and the use of bichromated gum arabic in mounting. Dr. Esquerdo contributes a paper on the Treatment of Placental Remains in the Uterus. From the editorial pen there is a lucid summary of our present knowledge of the etiology, symptoms, and treatment of the so-called Spanish influenza, of which our Iberian colleagues had an early and abundant experience; their practical acquaintance with this epidemic is further shown in another series of short articles dealing with the disease from various points of view, by various well-known scientists, such as Dr. Farreras, Dr. Freixas, and Dr. Moragas, chief of the bacteriological laboratory of the Santa Cruz Hospital. The opinion of the latter observer is worth quoting, being to the effect that in the present epidemic there was something more than Pfeiffer's bacillus, the pneumococci, the diplo-streptococci and accessory bacteria which he isolated from his cases, as the initial cause of the infection; that it seemed as if the influenzal infection, benign in itself, as seen in the earlier cases of the epidemic, prepared the soil for the colonisation of the accessory bacteria which, by transmission from one patient to another, acquired an unusual virulence and gave rise to complications of extreme gravity. These views are of interest to compare with those expressed in our leading articles on the same subject in last week's issue of THE LANCET and in the present number. It would seem that in many countries work is proceeding on similar lines and that the results obtained point to similar conclusions. Another section of the publication is devoted to abstracts from other journals, both Spanish and foreign, the latter part being very copious, and embracing all the chief medical periodicals of the world, over 20 pages arranged under various headings being given up for this purpose. Another portion is dedicated to reviews of books and a list of recent publications. One interesting feature of the *Revista Española*, which should not be allowed to pass without attention being drawn to it, is that each original article is accompanied by a *résumé* in French, a delicate and thoughtful concession for the benefit of those of its readers who may not be conversant with Spanish. We heartily congratulate the editorial staff on the excellence of their new medical periodical and wish it every success.

FRENCH SUPPLEMENT TO THE LANCET

Under the Editorial Direction of

Professor CHARLES ACHARD,
PROFESSOR OF PATHOLOGY AND THERAPEUTICS IN THE
UNIVERSITY OF PARIS.

AND

Dr. CHARLES FLANDIN, D.S.O.,
MÉDECIN-MAJOR DE 2^{ME} CLASSE; CHEF DE CLINIQUE
À LA FACULTÉ DE PARIS.

GUNSHOT CONCUSSION OF THE SPINAL CORD.¹

By HENRI OLAUDE,

PROFESSOR IN THE PARIS FACULTY OF MEDICINE; PHYSICIAN TO THE
PARIS HOSPITALS;

AND

JEAN LHERMITTE,

FORMERLY DIRECTOR OF THE CLINIC IN THE PARIS FACULTY
OF MEDICINE.

CONCUSSION of the spinal cord had already been an object of study before the present war era, but authors were only able to devote themselves to a description of the anatomical and clinical manifestations following on direct blows to the vertebral column or on falls from a height. Experimentally it was also possible to observe the lesions produced by successive blows on the vertebrae. We may recall the studies which had already established the existence from the clinical and anatomical point of view of concussion of the nervous centres, notably of the cord, because we wish to limit this account to the description of functional disorders and alterations in the cord which occur in those who have been subjected to gunshot injury, but in whom the cord has not been directly damaged by the missile. We are speaking here of traumatism due to the bursting of shells near the patient, or of wounds produced by projectiles which have not struck the cord itself.

I.

Concussion of the cord may be divided into two categories: (a) Indirect concussion, resulting from the bursting close to the patient of large shells, and in which the symptoms are caused by sudden variation of pressure. (b) Direct concussion, produced by the impact on the vertebral column or at a certain distance from it, of various projectiles (bullets, shell splinters, &c.), but in which the cord and its membranes have not been damaged by the missile. Such is the distinction which we have endeavoured to make in our previous work on this question. In both cases the spinal lesions are associated with the agitation of the nervous centres which have not been directly injured by the missile.

(a) *Indirect concussion.*—Indirect concussion includes those cases in which spinal paralysis occurs as a result of the explosion of projectiles of large calibre, and in which it is impossible to find any external wound as the explanation. From the beginning of the war these facts arrested the attention of medical officers; they have been attributed to the action from a distance on the central nervous system of the "wind from the bullet," but it is necessary to subject these observations to a critical and careful study in order to discriminate between disorders of organic origin and those of a psycho-neuropathic nature.

In France the cases of Sencert, of Ravant,² of Guillaud,³ of Heitz,⁴ of Babinski,⁵ of P. Marie and Chatelain⁶ have put beyond a doubt the existence of motor and sensory disturbances due to organic lesions of the cord in patients showing no evidence of any wound, but who were within the range of an exploding shell. A. Léri⁷ has collected most of these facts in a critical study.

Functional disorder may supervene immediately after the explosion. The patient is unable to use his limbs, he has the impression that they have been carried away, whilst at the same time he often complains of severe pain in the back. Sometimes disorders at first little noticed become accentuated some hours later. On the other hand, in some cases paralyzes, which before had been general, are seen to lessen and to become limited to certain limbs (Lhermitte⁸). A. Léri⁹ has insisted lately on the presence of "delayed" concussion, in which several days and sometimes even weeks after the explosion the first important gross symptoms of organic lesion have made their appearance.

The spinal syndrome following concussion due to explosion generally assumes the aspect of a quadriplegia or a paraplegia caused by transverse myelitis. The paralysis is accompanied by changes in the tendon reflexes, by

disturbances of sensation, weakness of the sphincters, and trophic phenomena (bed-sores), such as are found in organic spinal lesions. But it should be borne in mind that there may be partial paralysis, anaesthesia of abnormal distribution, and retained reflexes which make the diagnosis doubtful, at least at first, because the hypothesis of simple functional disease is not easy to eliminate. The organic signs then only develop slowly. Such are certain muscular atrophies indicating an alteration in the grey matter of the cord, and giving, on electrical examination, the reaction of degeneration. These amyotrophies, moreover, tend to improve.

The evolution of these paraplegias or partial paralyzes occurring after concussion varies according to the extent and gravity of the lesions. Relaxation of symptoms or their transformation into others is fairly common. For example, paralysis, flaccid at first, tends to become spasmodic. Nevertheless, the prognosis often continues quite favourable. A fatal termination, however, may occur either during the early hours or days as the result of shock, or later from pulmonary complications or various infections.

It is difficult to follow completely the history of indirect spinal concussion caused by explosion, because the morbid anatomy, and, above all, the histology of the lesion has not yet been investigated. Lumbar puncture, it is true, has shown in some cases the presence of hæmorrhage into the cerebro-spinal fluid or the remains of hæmorrhage (albuminose, xanthochromia), which has induced certain authors to deduce that spinal lesions are probably hæmorrhagic in type. There is no doubt that hæmorrhagic foci are present in many cases, but at the same time we cannot exclude the view of Roussy and Lhermitte,¹⁰ who hold that in a certain number of cases the nervous agitation caused by the deflagration has produced a direct traumatism of the vertebral column, and that the spinal concussion will therefore be of the same nature as the second category of spinal lesions, to which we have given the name of direct concussion.

The following has been urged in support of the hypothesis. The concussed man is often thrown to the ground, blown up, bruised, or buried, so that the rôle of agitation is not easy to distinguish from that of direct injury. Moreover, even when a single explosion can be shown to be the cause it occurs in the most typical cases behind the patient, who gathers the impression of having received a blow on his back or loins (Léri). There would thus be produced a sort of blow on the vertebral column, and we know as a fact that in these patients ecchymoses do occur in the limbs and certain other parts of the body exposed to the deflagration, which, acting like a blow, causes hæmoptysis, hæmaturia, and the like. It is possible that the same may hold good in concussion, or that the blow caused by the explosion is superadded to the phenomena which accompany atmospheric compression or decompression—factors often brought in to elucidate the pathogeny of concussion from explosion. Roussy and Lhermitte,¹¹ from a study which they have made of these symptoms, have formulated a theory which brings the symptoms of indirect concussion into close association with those of direct concussion. The impact—violent and limited by the edges of the cone of compressed gas to the spine or paravertebral region—would be comparable to the impact of a projectile. In each case, the authors say, the impact is transmitted to the nervous or spinal elements by the cerebro-spinal fluid, the sole difference being that in direct concussion the immediate traumatic agent penetrates and bruises, whereas in concussion caused by pure explosion there is commotion and agitation only.

It appears, then, that the study of direct concussion ought especially to give us interesting information, seeing that it appears to resume in a more general way the story of spinal concussion.

II.

(b) *Direct concussion.*—In our first study of direct spinal concussion (October, 1915) we demonstrated that the passage of war projectiles through the vertebral canal or its imme-

diate neighbourhood (fracture of the spinous processes, for instance), even when the dura mater is not injured, leads, by the violence of the impact, to a series of phenomena suggesting a lesion of the spinal cord. Further, direct concussion of the cord may result from the passage of a projectile into the spinal muscles or from the impact of neighbouring bony surfaces (ribs, spinous processes, scapula) on each other. This is direct concussion as a result of impact at a distance from the spine. The clinical phenomena are the same whether they result from indirect concussion (at a distance from the spine) or from direct (by traversing the spine).

Spinal lesions always attain their maximum intensity at the level where the violence is applied, and, of course, the disturbances observed depend on localisation of these lesions at different levels of the spinal cord.

We shall now study these disorders according to the part injured.

Cervical region.—M. Pierre Marie and Madame A. Benisty¹² have described the *transient quadriplegia* which follows injury to the cervical region; they have also pointed out the frequency of spinal hemiplegia of the concussional type which usually changes to brachial monoplegia. We have seen many cases of *permanent quadriplegia* produced by concussion in the upper cervical region. On a stage of flaccid paralysis of the four limbs there follows a more and more marked tendency to spasm and the paralysis becomes complicated by sensory disturbances, both subjective as well as objective, of spinal or radicular origin. In three cases a Claude Bernard syndrome of cervical type was present, and in one case the Claude Bernard-Horner unilateral syndrome made its appearance.

We have also seen a *primary brachial monoplegia* occurring both as a flaccid and secondarily spasmodic type; this monoplegia is usually associated with subjective and objective sensory disturbance, of radicular distribution, sometimes very obstinate.

Brachial diplegia is one of the most curious of the clinical types of cervical concussion. It occurs early as a sequel to certain injuries of the nape of the neck (transverse retro-vertebral bullet-tracks). The upper limbs are from the first completely paralysed, even while the lower limbs remain unaffected, and it is not without astonishment that some days after the injury the wounded man is to be seen standing and walking about, whilst his upper limbs, still completely paralysed, hang inert at his sides. Among the most characteristic symptoms of this clinical type we may notice shooting pains of radicular type and disturbances of sensation, especially concerning deep sensibility and tactile sense, with greatly increased interval at which compass pricks can be separately discerned, and even after the patient has recovered adequate movement of the hands the astereognosis persists. Finally we must add, to complete a very special clinical picture, frequent want of coördination of the movements of the lower limbs noticeable in the erect attitude and becoming manifest in the upper limb when movement reappears (asynergy, dysmetry), all manifestations of cerebellar nature.

This concussional brachial diplegia appears to us always to terminate favourably; movement returns little by little in the paralysed limbs, but their functional use is disturbed for a long time by asynergy or dysmetry of cerebellar type as much as by the ataxia associated with alterations of deep sensation. These last phenomena persist long into the remote phase, when the recovery of motor power is nearly complete. In two cases which we studied these cerebellar disturbances existed without paralysis or any important disturbance of sensation. Such a patient presents the staggering, tipsy gait of cerebellar lesion, whilst his movements are sudden and spasmodic, and examination confirms the presence of spasticity. This cerebellar spasmodic form of spinal concussion of the cervical region appears to us to be of favourable prognosis, for the incoördination, though well marked, passes off rapidly.

Besides these well characterised types we must include a series of *abortive forms* which vary according to the predominance of one or another symptom.

Dorsal region.—Concussion of the dorsal region gives rise to a symptomatology of which the gravity is variable from a paresis of the lower limbs lasting but a short time to a complete paralysis such as occurs after complete section of the cord, along with all intermediate types. Generally the symptoms come on with striking rapidity; motor and sensory functions apparently much involved are re-established, at least to some extent, after some weeks. Flaccid paralysis

from the beginning becomes transformed in these as in the cervical forms without much delay into spasmodic paraplegia without gross sensory changes. The bladder and rectum are generally involved.

Lumbar region.—We have seen only very few cases of direct concussion of the lumbar region. Their symptomatology depends upon the height of the lesion and the addition of radicular lesions to the spinal. There is no need to insist on a common clinical picture, which is that of compression or division of the cord, capable of easy analysis.

III.

Morbid anatomy.—Cerebral and spinal concussion are regarded by most authors as based upon an anatomical substratum, of which hæmorrhage, associated or not with softening, is the usual lesion. We have been at pains since 1915, by histological examination of numerous cases, to combat this opinion, founded more on imagination than on exact anatomical examination. Hæmorrhagic foci are seen, but less frequently even than meningeal hæmorrhages, and they are not the essential and characteristic lesion of concussion. Direct concussional agitation of the nervous system leads to changes of two kinds, *diffuse* and *local*, both of the necrotic type.

Local changes.—These we have described under the term *insular necrosis*. They consist in more or less extensive foci, generally situated exactly at the level of the point of application of the injury, whether this be actually vertebral or in the vicinity of the vertebral column. In these foci the nervous elements—axis cylinders, myelin sheaths, and nerve cells—are in process of destruction or already completely transformed, whilst the neuroglial elements are in process of proliferation and new blood-vessels are being formed. The whole appears to be a process of pure necrosis without either thrombosis or hæmorrhage. Later on proliferation of the fibrillary neuroglia proceeds and disposes of the last remains of the granular bodies. In some very severe cases the interstitial elements themselves die and the focus is absolutely necrotic. The tissues of the focus are absorbed and a cavity is formed, surrounded by a neuroglial network. This observation is not devoid of interest; the appearance of the cavities in syringomyelia exhibits the most marked analogy with the loss of substance occurring in concussion.

Diffuse changes.—The diffuse changes which we have described under the term of acute primary degeneration of the spinal tracts are apt to elude observation, and can only be studied properly by the silver method and in longitudinal sections. The axis cylinders are then easy to see broken up in larger or smaller fragments, pea-shaped or moniliform. The nerve fibres have for the most part lost their parallelism, they are retracted, curled on themselves, and cross one another. Around the broken fibres are grouped the granular bodies of neuroglial origin, containing in their protoplasm the debris of axis cylinders and amœboid cells with protoplasmic processes dissociating the myelin fibres which surround them.

The structure of the grey matter is not easy to make out. The ganglion cells are loaded with lipochromes, and, above all, the protoplasm appears full of chromophile granules fused in large irregular lumps. This change appears to us characteristic of spinal concussion.

We may add that the central canal is often dilated between constrictions, and there is often desquamation or proliferation of its epithelium; curiously enough, the fibres of the roots take part in the process of acute primary degeneration noted higher up in the fibres of the cord.

We consider, then, that the anatomical lesions, of which we have here given a general picture, and which we have described elsewhere at length, are of a type so distinct that they merit a place apart in the record of the morbid anatomy of spinal lesions. The results of these inquiries are of great interest because they show that spinal concussion is not, as is generally supposed, dependent upon so simple a change as hæmatomyelia, but can only be regarded as a complication of changes occurring in the spinal cord and originally quite distinct.

We conclude further that concussion of the spinal cord, and especially direct concussion resulting from impact on the vertebral column or in its neighbourhood, should, from its etiology, its clinical course, and its morbid anatomy, be assigned a place apart in war neurology. Its history is still incomplete, but we thought it would be of interest to surgeons and physicians to have pointed out to them at this stage the principal features, for the condition deserves to be better known and not to be confused with the other common

traumatic changes in the cord on the one hand, or with functional nervous disorders on the other hand, in view of the very different prognosis and treatment needed by these diverse spinal syndromes.

CONTRIBUTION TO THE STUDY OF THE MANIFESTATIONS OF EMOTIONAL SHOCK ON THE BATTLEFIELD.

BY CL. VINCENT,

PHYSICIAN TO THE PARIS HOSPITALS; FORMERLY MEDICAL OFFICER TO THE 46TH AND 98TH R.I. AND TO THE 44TH S.O.P.

Many observations have been published dealing with mental disorders or nervous troubles following on the emotions experienced on the battlefield. In nearly all these cases the connexion between the mental and nervous troubles observed and the emotional shock which has produced them has been established on the evidence of the patient. But experience has shown us that in most cases the man has given no account of the first manifestations of his emotion. We are also aware how rapidly in the light of reflection—either spontaneous or produced by systematic questioning—the ideas which the man has about what has occurred to him become changed. If we add that in many cases the man declares that he lost consciousness it will be readily understood how difficult it is to establish the origin of mental and nervous troubles following on emotion, especially emotional shock.

The observations which recount the phenomena presented by soldiers from the moment at which the emotion occurred until their return to the normal state have, in my opinion, an entirely different value. These observations show, in the first place, that many of the disorders attributed to concussion are really manifestations of emotion; and, on the other hand, they establish the relationship between phenomena observed in certain soldiers behind the lines and at army dépôts, and the quasi-instantaneous manifestations of emotional shock to which men on the battlefield have been subjected. Consequently they help, to some extent, in unravelling the nervous and mental troubles seen during the days which follow the emotion, and which are difficult of interpretation when their origin is unknown. The same observations also explain, in a measure, the differing values placed by neurologists on phenomena of the same origin, to be explained by the fact that they have seen their patient on the battlefield only and have not followed the development of the first phenomena shown; or else their observations have been made behind the lines or at dépôts where they have only seen secondary and late phenomena and not the initial stage. These neurologists are talking of two consecutive and differing aspects of phenomena having the same origin.

Account of Case.

In the account which follows it has been possible to watch the man from the moment of infliction of the emotional shock to the instant at which the phenomena following the emotion disappeared. The physical and mental disturbance lasted about a fortnight. All phases have been noted.¹

¹ In France various regimental medical officers (Volvenel: *Progrès Médical*, 1918; Oberthür et Duroselle: *Revue Neurologique*, 1916; Dide: *Emotions*, Alcan, éditeur, 1918) have published observations made *separately* on the field of battle.

A—, 11th Comp., 98th R.I., aged 23 years. On active service for two years. Not alcoholic. Had not been overworked. The regiment had just had a long rest. Had never suffered from concussion.

On August 20th, 1917, at 4.35 A.M., while his company was advancing to take A— Wood, a shell of medium calibre fell on the edge of the trench whence they were starting. It slightly wounded some of them and affected another without touching him, without even throwing him to the ground, but in such a way that he was unable to follow his comrades to the assault. I was a few dozen metres away, and being warned at once ran to him, less than 5 minutes elapsing from the fall of the projectile to the moment at which I reached the man. He was sitting at the bottom of the trench, some yards from where the shell had fallen. He was trembling all over. It was impossible to get a word from him except, "Oh, my ears!" I tried to help him, but he paid no attention. I tried to make him stand up, but he remained inert. But it was "the hour H—." The men were attacking. Some had already fallen and I could not remain with A—. I said to him, "Go to the aid-post of the battalion as quickly as you can."

When I returned to the aid-post at about 10.45 A.M. my man was there. The orderly said to me, "He came in 5 hours ago." But from the trench where he had been affected to my regimental aid-post in the ravine of C— was at least 1200 metres. Be-ides, he had to pass the battalion aid-post. It had not, therefore, taken him long to come.

Examination on August 20th at 11 o'clock—that is to say, 6½ hours after the shock. I put a certain number of questions to him; he answered slowly after reflection, but precisely. He gave the following information: "It was 4.30 A.M. when the shell fell. I believe it was a '105.' It fell half a metre from me on the edge of the trench. Two of my comrades were wounded. One was wounded in the face. They are gone. I do not know what has become of them. I lost consciousness, but not for long. I do not know exactly for how long. When I came to myself I was trembling. Some men were passing who accompanied me to the aid-post of the battalion. I did not know where I was. I followed the stretcher-bearers in order to get here—i.e., the regimental aid-post."

Condition at the moment of observation.—Appearance dull and tearful. Pulse 110, respiration 36, although he had been lying down for some time. There was a fine tremor of the hands, but sufficiently coarse to be seen at a distance. His body did not tremble. He complained of a deep pain in his ears. He was conscious of whistling and buzzing. Auditory acuity diminished; he could hear the speaking voice at half a metre. Tendon, cutaneous, and pupil reflexes normal. Sensation normal. No contraction of the visual field.

I escorted him to the regimental aid-post, where he lay on a hanging stretcher covered by a blanket. The rest of the day of August 20th, the night of the 20th-21st, the day of the 21st, he did not stir either to eat or drink (refusing what was offered to him) or to urinate.

August 21st: Still trembling; still dull. He only answers slowly, as if with great effort, the questions put to him. Pulse 120, respiration 42. Blood-pressure: Systolic 135, diastolic 90. Same state of auricular apparatus. As he had not passed water since the morning of the 20th the hypogastric region was percussed out. A suprapubic dullness was present. He was asked to pass water. Micturition took some time. He succeeded in passing some grammes of urine, which examination showed to be normal. Lumbar puncture; cerebrospinal fluid normal. (The lumbar puncture was carried out after retention of urine was discovered.)

August 24th: Has completely emptied his bladder this morning—about 100 g. of urine. Trembling much less. Pulse 110; respiration 42. Bare in the same condition. Appearance less dull. It was easier to make him answer, although it still took a long time to get anything out of him.

In order to estimate his intellectual activity, we asked whether he had written home. He said that he had not, because, in the first place, he was trembling too much, and also it was not long since he had written. Usually he wrote every three days, and he had written before going into the line. "When we said to him: 'But that is five days ago, you should have written,'" he answered: "I did not think that we had been so long in the line."

He had lost count of time. He thought that it was July, whereas we were in the month of August. We gave him a paper to read. He read with difficulty, without fluency, and very differently from the way in which he read afterwards. After reading a few lines we asked him what he had read, but he was unable to say. We made him count up to 20, which he did slowly and with difficulty. We made him count from 100 to 120, which he did still more slowly. Sometimes two or three seconds elapsed between two consecutive figures. We gave him some sums to do, addition, subtraction, and multiplication, which he did correctly, or nearly so. These he now took a long time to do and all were incorrect, even addition and subtraction. In these the results of the first two columns of addition and subtraction were correct, but those of the other columns were wrong. The results were wrong when he attempted addition and subtraction of more complicated figures. Also they were wrong because each time he had forgotten to carry. He was unable to fix his attention.

August 26th: Reading more freely than on the 24th. Counts without stopping between the numbers. Knows which month it is. Cannot remember the meaning and the words of a sentence which he has been made to copy. We again made him do the same sums he had done before. He did them very slowly. All were wrong.

August 30th: Respiration 25. Still trembled slightly, especially in the right hand. Was, however, able to write home on August 28th. The condition of the ears was improved, even though the whistling and buzzing persisted, especially in the right ear. He is fully aware that it is the month of August, and that the attack was carried out on August 20th. He counts up to 20 in 7 seconds. It takes him 15 minutes to do the sums. They are still wrong, but the mistakes are fewer.

Sept. 4th: Respiration 26. Blood-pressure: Systolic 105, diastolic 70. The trembling has disappeared even in the right hand. The ear condition is still better. He suffers no longer; he is still a little annoyed at times by the buzzing, and auditory acuity is not normal. He has recovered his appearance. He no longer has the dull air which he had. He writes home every day and occupies himself in one way or another. When he was told to come in to be examined he was looking for wood to make a door to the aid-post. He did the sums in 5 minutes 25 seconds. The addition was right. There was one mistake in the subtraction and one in the multiplication. Returned to duty.

Oct. 16th, 1917: Has been on duty since the day he joined his company. Intellectual activity normal. Did the sums as described above in 6½ minutes. The addition was correct; there was one mistake

in subtraction and two in multiplication. The ear condition was not yet quite normal. He complained of buzzing in the ears, especially in the evening. He could not hear the watch ticking at more than 20 cm. from the right ear. Pulse 72. Respiration 24. The trembling had disappeared.

Discussion of Causation.

Before going further, the following question at once arises. To what cause are we to attribute the troubles which developed in A— immediately after the explosion of the projectile which fell on the edge of the trench where he was awaiting the assault?

There can be no doubt that A— was the victim of a labyrinthine concussion. It is to this that we must attribute the disturbances of hearing, the deep and diffuse auricular pain. But are we to regard the other phenomena as evidence of cerebral concussion or of emotion?

In my opinion this man is suffering from emotion and not from cerebral concussion. He did not lose consciousness or, at least, entire consciousness for a moment after the shock due to the explosion, and was far removed from the state of consciousness of a man struck down by apoplexy or by cerebral concussion.² I saw him a few minutes after the explosion of the shell. He was sitting, not lying, in the trench, trembling, and his expression was at the same time dull and lacrymose. He was groaning: "Oh, my ear!" On the other hand, questioned six hours after the shock, he showed that he remembered the circumstances of the occurrence. He said to me: "It was a '105,' which fell on the edge of the trench and slightly wounded two of my comrades." And what is more, he had understood the order which I gave him: "Go to the aid-post at C—," and half an hour afterwards he was there. It was 1200 metres from the trench to this aid-post, and the ground was incredibly cut up by the shells. A man suffering from concussion, who has lost consciousness, who is "knocked out," who is in transient or prolonged coma, does not behave like this.

Here, on the other hand, are some details of the observation of a man suffering from slight concussion whom I had the opportunity of seeing about 20 minutes after the shock. He was struck on August 19th in a trench at W—, about 200 yards from my aid-post. He arrived escorted by two comrades. His face was black with smoke. In giving an account of himself he said to me: "I came out of the dug-out and sat down on a windlass. Then, without knowing why or wherefore, I found myself on the ground. There I had to remain for a while. When I began to come to myself I was surrounded by smoke. I thought it was gas."³

Now, although this man had lost consciousness for a very short time, he was totally unable to give an account of what had happened to him. Loss of consciousness in the man suffering from concussion was totally different from the loss of consciousness which occurred in the case we are discussing immediately after the explosion of the shell. Therefore it is not admissible to say that A— is suffering from concussion, whilst at the same time he exhibits phenomena which, taken as a whole, are characteristic of emotional shock—viz., trembling, tachycardia, and tachypnoea.

Nevertheless, two objections can be made to this point of view: (1) our man showed evidence of labyrinthine concussion; (2) he himself described the state in which he was immediately after the shock as loss of consciousness.

Let us now discuss these two objections.

(1) The fact that a man suffers from labyrinthine concussion by no means implies that he is suffering from cerebral

concussion. Cerebral concussion is one thing, labyrinthine concussion another. One or other may exist alone. Cases of labyrinthine concussion without cerebral concussion occur frequently. Here is one which I saw from the very moment at which it was produced. A sentry and my assistant medical officer F— were looking through a loop-hole at an advanced post, their heads close together. The sentry saw a *boche* at a loop-hole opposite about 30 metres away. He brought his rifle to his shoulder, pointed it in the direction of the enemy and fired. F— turned away quickly, putting his hand to his left ear. At the report he felt a severe pain in his left ear, after which he heard nothing more in this ear. A moment afterwards he perceived a very sharp whistling. All that day and the next the whistling remained, and the deafness persisted. It was nearly a week before the trouble disappeared. There was in this case auricular concussion without cerebral concussion. I may add, also, without emotion.

(2) As to the statement of the patient that he had lost consciousness, it is not enough to justify the doctor in concluding that the man lost consciousness in the same sense as a patient suffering from cerebral concussion. I saw the man at the time he declared that he had lost consciousness, I enquired in what his loss of consciousness consisted, and I can only repeat that this man did not lose consciousness in the same sense as a man suffering from cerebral concussion. Without doubt he had passed through a violent mental disturbance; later I shall endeavour to analyse this mental disturbance, but there was no loss of consciousness. A— is above all suffering from emotion, he is not suffering from cerebral concussion. The disturbances exhibited by him must be attributed to emotion, and not to concussion.

Sequence of Phenomena following the Emotional Shock.

I do not insist on the manifestations which determined the emotional shock in this man. I only wish to draw attention to the manner in which they unfolded themselves.

In the case of A— in the space of a moment a violent emotion has disturbed his physical and mental equilibrium; nearly instantaneously he was overcome by an intense trembling; his heart beats and his respiration became extremely rapid. His mental state was changed; his face took on a lacrymose and mournful expression; it was impossible to obtain from him an answer or gesture to show that he understood what was said to him. The reaction to emotional shock was therefore immediate.

Six hours after the shock some of the phenomena still persisted—tachycardia and tachypnoea. Others had become less and been modified. The trembling had diminished but not disappeared. His appearance was still stupid, but one could get into communication with him. He answered questions slowly as if it was an effort to do so, but he answered correctly, and he gave details spontaneously. Thus after six hours, and although he was under cover, the disturbance produced in my patient's organism by the emotional shock had not yet calmed down. Certain of the physical phenomena by which emotion shows itself persisted unchanged; others were present but in less degree. The mental state appeared to approach the normal.

But this improvement of mental state was but a truce. Indeed, on the third and fourth days after the shock the state of A— was as follows: tachycardia and tachypnoea persisted; trembling had become less and was localised to the right hand. But the mental state was more disturbed than it was six hours after the shock. A condition of stupor and pronounced mental confusion existed, which amounted to refusal of food and retention of urine. Thus, in the case of A— the primary period of psychic inhibition had been followed by a period in which a certain psychic activity was apparent; then this period of relative improvement gave place to a period of mental confusion with stupor.

At the end of about a week all the phenomena had begun to get less, and 14 days after the onset A— had recovered.

In A—'s case, then, emotional shock produced an immediate perturbation of the organism, the effects of which were felt for two weeks in the form of tachycardia, trembling, mental troubles in different keys and aspects, hence lasting long after the cause which had produced the shock was removed. So in certain cases the disorders following emotion on the battlefield which have been observed behind the lines or at the *dépôts* are only the primary or secondary phenomena by which emotional shock manifests itself, and which last after the cause which has disturbed the organism no longer exists.

² Some cases of cerebral concussion without loss of consciousness have been published (Guillain), but they are the exception. As a rule the concussed man loses consciousness under the shock which has struck him down.

³ This man also showed the presence of auricular concussion. Blood was running from his left ear, and with this ear he could only hear sounds with difficulty. Volatic vertigo (right unilateral inclination) was affected. When he arrived his pulse was 110 and his respiration 28. He was not trembling. An hour and a half later the pulse was 68 and respirations 20. This man spoke to me quietly, but at times he could not find certain words, so said one word instead of another. This slight aphasia decided me to do a lumbar puncture. This proved easy, and the cerebro-spinal fluid was found to contain a little blood. There appeared to be no head wound. Shortly after the examination my attention was drawn to the patient's helmet. The left half of the helmet was indented over a circular area about 2 cm. across. A projectile had struck it here. When the helmet was replaced on the man's head the depression was found to correspond with a small region which, on parting the hair, showed bruising and was painful on pressure. This area was adjacent to the point which surgeons regard as corresponding to the inferior extremity of the fissure of Rolando. In short, the cranium via the helmet had transmitted to Broca's area a shock which at once explained like the slight aphasia and the meningeal hemorrhage. This man was evacuated and recovered without sequel of his cerebral concussion. He had a left otitis media, and had to undergo a mastoid operation.

THE LANCET.

LONDON: SATURDAY, JANUARY 11, 1919.

The Neuroses of the War.

THE war, now happily, and finally we trust, come to a victorious end, will not be characterised in the histories of the future by any such limiting territorial epithets as have been assigned to all previous wars. Unique in its designation as the Great War, or even simply *The War*, it has also been unique, militarily speaking, in its air and sea, under-sea, land and even under-land aspects. From the point of view of medical science, further, it has certainly provided the stimulus for more sustained, more concentrated, more widespread and more fertile medical research than any previous event in the world's history. At its close we may now perhaps take the opportunity of passing in review the stages in the development of our knowledge of the neuroses of war, a subject which has been productive of clinical investigation to a quite unusual degree. Before the war the categories covered by the clinically descriptive terms of neurasthenia, psychasthenia, and hysteria were well recognised and more or less well differentiated and accepted, in this country at least. Into this time-honoured scheme came with upsetting suddenness and momentum the new conception of "shell shock" as a clinical entity; old terms were given up, and "shell shock" represented the latest and all-embracing idea in the neuroses or psychoneuroses. Men came home with "shell shock" on their labels, and soon both the medical and the lay mind were permeated with it; it was the cause of every functional disturbance, mental or nervous, and special hospitals were rapidly organised for the reception of the "shell-shocked." Ere long, however, calmer consideration and more painstaking research showed that under the term was included a multiplicity of clinical conditions, most, if not all, of which seemed familiar enough. Somehow there was at first a disinclination to think of the soldier—the "old contemptible," the volunteer, the patriot—as a possible subject of ordinary traumatic hysteria; but that war hysterics, and malingers, too, were appearing at base hospitals and in military hospitals at home could not be gainsaid. Gradually it came to be felt that "shell shock" was confusing by reason of its indefiniteness, and traumatic hysteria, traumatic neurasthenia, psychasthenia, and the rest seemed to come into their own again. If we mistake not, there is now appearing a tendency to group the war neuroses after the Freudian fashion, and to force them into the pigeon-holes labelled "conversion hysteria," "anxiety hysteria," and "anxiety neurosis."

But poor indeed would be the advance in our knowledge of the neuroses as the result of war experience were "shell shock" as a psychogenic or neurogenic factor to be minimised, or a sexual element in their genesis to be necessarily implied, by the adoption of a Freudian nomenclature. In our English fashion we have essayed a compromise between the old and the new, and many have come to regard the war neuroses as essentially identical with those of civil life, except in so far as the events of the battlefield are novel excitant factors and the instinct of self-preservation more potent than the instinct for the propagation of the species. The French, perhaps less apt than we to be influenced by precedent, less conservative, less bound by preconceived ideas, have divided the neuroses of war origin into "commotionné" and "émotionné" syndromes.¹ With that facility for new word-formations to which their language lends itself, they speak of the "commotionné," the "émotionné" and the "contusionné"; we have in the translation of our French Supplement followed tradition in rendering "commotionné" as "concussed," but have done so with regret. The *contusionné*, the patient with signs of local or general cerebral irritation and probably a somewhat blood-stained cerebro-spinal fluid, is, of course, clearly enough defined. The *commotionné* is the man who, after loss of consciousness from a shell explosion in his immediate vicinity, remains in a state of subcoma or obnubilation, with a variable degree of physical and mental inertia and of cerebral inhibition; his pupils are usually dilated, his pulse slow, and his reflexes diminished. The *émotionné*, on the other hand, does not as a rule lose consciousness in the strict sense (as Dr. C. VINCENT shows in his interesting paper published in our French Supplement); he has a quick pulse, moderate reflexes, and a pale, haggard or frightened visage; he trembles, and sweats; concentrated on his own *angoisse*, he is indifferent and inattentive to what goes on around except as it bears on his own safety and security. Such descriptions refer to the patients' states on their arrival at a C.C.S.; in the base hospitals the clinical appearances have changed to some extent. The *émotionné* has become a case of "emotion-neurosis"—like the anxiety-neurosis more or less; he is a pantophobe, with familiar psychical and physical symptoms. Or he may develop into an "emotion-neurasthenic" with physical and psychical overstrain, asthenia, and fatigability as the most prominent features. Or again, he may, ere he reaches the base, for that matter, have developed one or more of the pleomorphic manifestations of hysteria. Emotion-hysteria is common enough, but it should be clearly understood that hysterical phenomena do not form a constant and integral part of the emotion-syndrome, and may arise independently of emotional stimuli. It is comparatively rarely that the *commotionné* shows subsequent signs of hysteria; he remains, as a rule, an "inhibé," it may be, for months.

A schematisation of this sort may be perhaps rather cut-and-dry, and naturally cases presenting

¹ See in particular A. Léri, *Commotions et Emotions de Guerre* (Paris, Masson et Cie, 1918).

combinations of symptoms are met with; but it has much to commend it, and for practical purposes has proved, and is proving, useful and illuminating. And yet it leaves many problems unexplained, or at least only superficially elucidated—how much so can be gathered by a perusal of Dr. C. S. MYERS's interesting contribution in another column. Dr. MYERS indicates for us certain topics on which further investigation is desirable, and states that the mechanism of production of "functional dissociation" is still imperfectly understood. Emotion, suggestion, conflict (in a non-physical sense), maladaptation to environment, and so on, are factors whose evaluation remains to be determined. At this psychical end of the war neuroses there is, then, not a little for further research, in spite of the fact that in this country, as Dr. MYERS remarks and as we have always maintained, the mental aspect of the war neuroses has been elaborated at the expense of neglect of an equally detailed study of the accompanying somatic symptoms. Many have noted involvement of sympathetic, glandular, and reflex systems in emotion-neurosis and in emotion-neurasthenia, but only the fringe of the subject has been touched. Dr. MYERS pertinently asks whether functional dissociation may extend to these systems, and to what degree or "level." Similarly, in hysteria resulting from the war we should like to see more detailed investigation of the somatic and visceral accompaniments; so far from regarding such investigation as reactionary in view of the psychical nature of the affection, we feel that by it we should gain further insight into the extent of hysterical dissociation in somatic systems and learn useful criteria for diagnosis. It is not enough, in our view, to explore the recesses of the conceptual world by psycho-analysis or autognosis when the objective neural disturbances of the patient are analogous to what is found in certain endocrine affections or in certain organic conditions of the neuraxis. Dr. MYERS, albeit in an admittedly sketchy fashion, gives us enough clinical data for a realisation of the significance of investigation along such lines, and his contentions carry the more weight as coming from a professed psychologist. The varying orientation of our ideas on war neuroses during four years, apart from its intrinsic interest in the history of medicine, is of extrinsic importance for future diagnosis and treatment. Numerous, indeed, are the "unwounded wounded" at home or still abroad, and for a long time yet we shall have to deal with them therapeutically. To place them in their appropriate medical category is a matter of justice and equity; to separate the malingerer from the hysteric, the *commotionné* from the *émotionné*, the exaggerator from the *inhibé*, is a labour calling for knowledge and acumen. Treatment itself, as Dr. MYERS shows, has not been made a subject of systematic inquiry; successful workers, it is true, have published results in profusion, but there has been too little following up of cases for re-examination after an adequate interval. The war is over, but the physician's task is far from an end.

Lessons of the Influenza Epidemic.

• Epidemiology and Clinical Aspects.

FROM our review of the etiology and pathology of influenza in last week's leading article the complexity of the problems involved is apparent, and it is obvious that further investigation is necessary for their solution. This is especially true of the epidemiological aspects of the disease which have not figured prominently in the various papers which we have published; nor is this surprising, since the materials necessary for the foundation of a considered judgment have yet to be assembled.

Epidemiology.

In the highly valuable discussion at the Royal Society of Medicine on Nov. 23rd last Dr. MAJOR GREENWOOD provided data from the records of the Ministry of Munitions and the Royal Air Force which suggested that the incidence curve of the summer outbreak was closely similar to that of the first pandemic in 1889-90 and that the secondary wave partook of the characters observable in 1891-92. These data were, however, incomplete. For instance, an epidemiological explanation of the relatively greater mortality at younger ages in the present outbreak remains to be found. The official mortality figures of the Registrar-General's 96 great towns display the asymmetrical character of the autumn epidemic very clearly. The maximum number of deaths—7557—occurred in the week ending Nov. 9th, having risen to this height from 1887 in the week ending Oct. 19th. The decline again to this level has been more gradual, almost the same number of deaths, 1885, being recorded in the week ending Dec. 14th. An examination of individual towns suggests that the maxima occurred earlier in the seaports, but it is impossible yet to correlate either the severities or the rates of temporal extension in the outbreaks with geographical and economic factors. A perusal of the clinical and bacteriological papers in our own columns alone suggests the desirability of investigators not delimiting the field of inquiry too narrowly. Dr. HAROLD WHITTINGHAM and Dr. CARRIE SIMS, for instance, in our issue of Dec. 28th, 1918, drew attention to the clinical differences of the summer and autumn outbreaks, and inferred that the causal organisms must have differed. The observation is, of course, a very familiar one in the history of epidemic diseases, and has been made with especial frequency relatively to scarlet fever; it would appear to be consonant with our experience of scarlet fever to infer that the variation is not so much of the causal organism as of secondary invaders responsible for sequelæ of the primary disease. Dr. WHITTINGHAM and Dr. SIMS also refer to the "distinct tendency when an epidemic disease is raging to assign all maladies to the one common origin," and we suspect that they deprecate this tendency; yet it may be the more or less conscious expression of an important epidemiological truth. The clinical convergence of disparate types of disease in a given year or cycle of years and the clinical divergences of the same disease at different epochs are the foundations of that doctrine of epidemic constitutions which held so prominent a place in the teaching of our first epidemiologist, SYDENHAM, and depended upon wide experience and accurate observation. The total discredit into which the old theory has fallen is, of course, due to the fact that the biological prophylaxis of clinically

convergent types, such, for instance, as typhoid and paratyphoid infections, is distinct. But a heterogeneity from this point of view does not invalidate the claim that from another point of view such a group of diseases is homogeneous; just as a sample of men may be heterogeneous in political opinions but homogeneous as regards their incomes or occupations. The point we are making is of much importance, and unless it be kept clearly in mind epidemiology becomes logomachy. We have to inquire in the first place whether in the late epidemics any general morbid process has developed, and, if so, whether it can be identified with any recorded before and whether its course has been significantly different from that of any previous epidemic.

"There are in truth varied constitutions of the years, not dependent upon heat or cold, dryness or moisture, but rather upon some hidden and inexplicable change in the very bowels of the earth, whence the air is contaminated by such effluvia which predispose and determine towards this or that disease the bodies of mankind, so long as the dominion of the particular constitution endures, which constitution, its term having run, yields and gives place to another. Each of these general constitutions is characterised by a special fever peculiar to itself and not otherwise seen; such fevers we term stationary fevers."

Unlike SYDENHAM, we should regard the hidden change as being within the field of possible epidemiological research and not rest content with a vague metaphor, but the idea at the back of the passage cited appears to us still fruitful, and attention should not be diverted from it by too sedulous pursuit of bacteriological details, important as these latter are from other points of view.

Clinical Aspects.

In its clinical aspects epidemic influenza has been characterised in past outbreaks by very varied manifestations, and attempts have been made to separate out different types of the disease with indifferent success. The epidemic at present so widely distributed is no exception to this rule; indeed, so protean have been its manifestations and so unequal its virulence, that some doubts have been expressed, chiefly in the lay press, as to the disease being influenzal in origin. Various fantastic theories have obtained a wide currency with little or no basis of support. One fact that seems to emerge clearly, through intensive study of the epidemic from the clinical and pathological points of view, is that the epidemic is influenza complicated by certain secondary organisms or infections. The complexity in the causation, which is suggested by bacteriological observations, may be, and probably is, an important factor in the variability of the clinical manifestations of the disease; with further correlation of the bacteriological and clinical observations the diversity of clinical types may find accurate explanation, and different forms of the disease may be associated with different secondary infections. The clinical features of influenza become somewhat more easy of explanation in the light of the pathological conditions observed in fatal cases, and these are admirably described in the paper by Dr. ADOLPHE ABRAHAM, Dr. NORMAN HALLOWS, and Dr. HERBERT FRENCH, which we published on p. 1 of last week's issue of THE LANCET. They point out that even in the so-called pneumonic cases the lung lesions are only a part of the morbid changes usually found. They regard the fatal forms of the disease as a septicæmia of influenzopneumococcal or influenzostreptococcal origin with more or less marked local

changes in the lungs. The lung conditions found post mortem are even more varied than the clinical features of the disease, and comprise bronchitis, bronchiolitis, broncho-pneumonia, hæmorrhage, infarct, collapse, œdema, multiple abscesses, gangrene, interstitial emphysema; indeed, practically all possible morbid lesions except that lobar pneumonic consolidation is exceptional—a somewhat surprising fact in view of the physical signs, which frequently appear typical of this condition. The pleural manifestations are also variable, and range from localised dry pleurisy to large effusions of thin sero-purulent fluid. Without attempting enumeration of the lesions found, it is important to emphasise the frequency of renal changes, amounting to actual nephritis in a very considerable percentage of the fatal cases—a fact liable to escape observation clinically unless a routine examination of the urine is carried out, for œdema is absent. This is of especial importance in cases where convalescence is delayed. The pathological changes found allow little room for doubt that the fatal cases are of toxæmic or septicæmic character, and the discovery of organisms in the blood during life and in the internal organs immediately after death affords confirmation of this view.

A critical account of the symptoms of the disease will be found in the paper by Dr. FRENCH and his collaborators; but it may be worth while to point out that the character of the symptoms seems to differ in different parts of the country, and even in cases in the same place at different times. For example, some cases with pulmonary complications have been associated with an almost incessant cough, others with copious expectoration, while in some other cases with marked pulmonary involvement very little expectoration has occurred. Laryngeal, pulmonary, and lethargic varieties have been described. The types of case observed in the last few months have varied from mild febrile attacks associated with malaise, general pains in the back, limbs, and head, feelings of great prostration, thickly coated tongue, and almost complete loss of appetite, to fulminating cases fatal within 24 or 48 hours. A special feature, even of mild cases, in some parts of the country has been epistaxis, often frequent and copious. Other hæmorrhagic phenomena have been present in the septicæmic or pneumonic cases, including hæmoptysis and hæmatemesis. On the other hand, purpura seems to have been uncommon, although such might have been expected in the septicæmic cases. The colour of the patients with severe pulmonary complications is one of the features which has attracted almost universal attention, a peculiar dusky pallor, described as heliotrope cyanosis, being of most sinister prognosis, even though it may be present with only moderate pyrexia, a deceptively good pulse-rate, and not very extensive physical signs. The point is emphasised by the three observers just mentioned, who call attention also to the absence of orthopnoea and the comparatively slight degree of cardiac dilatation which may be present even in cases dying rapidly with marked cyanosis. These are points which strongly support the view of the septicæmic nature of the cases as opposed to the pulmonary origin of the symptoms. The frequency with which suppuration in the sphenoidal sinuses has been found in fatal cases, as well as the occurrence of severe epistaxis even in mild cases, and the existence of pharyngeal or laryngeal inflammations in some forms of the disease all serve to suggest that the channel of

¹ Sydenham: *Observationum Medicarum*, lib. 1., cap. 2, par. 5.

infection is usually by the upper air-passages. The use of antiseptic gargles and nasal douches as a preventive appears, therefore, to be well founded, and the use of a gauze mask over the mouth and nose by nurses and medical men in attendance on cases in institutions seems a reasonable precaution. The physical signs in the pulmonary type of case are as variable as the other features of the disease. There may be general or local catarrhal signs, scattered patchy consolidation or signs strongly suggestive of lobar involvement, though they are in reality due to aggregations of broncho-pneumonic areas. Neither diagnosis nor prognosis can be gauged by physical signs too closely. In other cases signs of fluid may develop rapidly, but diagnosis of the lung or pleural conditions is often rendered difficult by variations in the physical signs from day to day. An interesting condition which has been observed in a few cases is subcutaneous emphysema—sometimes localised, occasionally widespread.

Treatment.

In regard to treatment no satisfactory routine measures can be said to have been discovered as yet. The various "specifics" suggested seem hardly to justify the claims made by their partisans. In all cases some such scheme of expectant and symptomatic treatment as that outlined by Sir THOMAS HORDER in THE LANCET of Nov. 23rd last should be adopted, and this with efficient nursing may be all that is required; but in the severe pneumonic, toxæmic, or septicæmic cases the therapeutic resources of the practitioner may be taxed to the utmost and yet fail, for some of the cases, notably those with the peculiar "heliotrope" cyanosis, seem all but hopeless. The question of treatment by vaccines and serums is still an open one. Evidence seems to be accumulating as to the value of prophylactic inoculation with mixed vaccines of the Pfeiffer bacillus, the pneumococcus and the streptococcus. We may hope that statistics on this question will be forthcoming eventually, and that the value of the procedure will be authoritatively appraised. Anti-streptococcus serum has been used by many observers in the toxic cases, but the results recorded seem to offer but moderate encouragement, though its use is rational in cases in which the presence of the streptococcus has been established. The use of vaccines in the treatment of the disease itself has been deprecated on the supposition that the induction of a negative phase might affect the course of the disease unfavourably. In a paper published in THE LANCET of Dec. 28th by Dr. W. H. WYNN this objection is denounced as theoretical, and the value of vaccines in acute influenza is strongly affirmed. This question, like many others, must be regarded as still *sub judice*, but we may hope that when the experience afforded by this epidemic has been collated some practical knowledge may result which, while not preventing further epidemics, at least will render them less serious in their effects.

Rabies and its Treatment in this Country.

OUR insular position and the spirited action of the Board of Agriculture under Mr. WALTER LONG resulted in the complete immunity of Britain from rabies for more than a decade. The faint academic interest felt for an infection occurring only on the continent has been violently stimulated by the recent outbreak of rabies in Devon and Cornwall.

The airship and the dislocation caused by war conditions have made the rabies blockade ineffective, at all events for the moment, although no one will have any sympathy for the blockade-runner whose thoughtless selfishness may result in such terrible consequences to his countrymen. Hitherto anti-rabic treatment has not been available nearer than Paris, but Dr. EMIL ROUX, before relinquishing the office of director of the Pasteur Institute in Paris, with which he has been so long and honourably associated, rendered a very valuable service to this country by enabling anti-rabic treatment to be given with material sent over at frequent intervals from the institute to the Local Government Board. It is practicable, in the experience of the institute, to rely upon glycerine and cold to preserve the virus in a proper degree of potency for several weeks, and by these means to supply for use in this country spinal cords representing fixed virus of different ages, from which emulsions can be prepared and treatment can be given on lines parallel to those used at the parent institute. The Local Government Board have now announced to the local authorities of Devon and Cornwall that in place of the elaborate arrangements which had recently been made to facilitate the journey to Paris of persons known to have been bitten by rabid animals, anti-rabic treatment can in future be given at Plymouth, where the arrangements have been placed under the charge of Dr. W. L. PETHYBRIDGE, pathologist of the South Devon and East Cornwall Hospital. District councils are authorised in this connexion to pay reasonable sums for the maintenance in Plymouth of persons requiring treatment who cannot stay there at their own expense for the two or three weeks necessary for the completion of the course.

This provision of anti-rabic treatment is obviously necessary while cases of rabies in dogs and other animals continue to occur in these two counties. The disease has not disappeared, though there is reason to believe that the various restrictions on the movements and keeping of dogs, and the compulsory muzzling requirements of the Board of Agriculture, have already greatly reduced the opportunities of its spread, and apparently no cases are occurring outside the two counties named. It is understood that about 30 persons have actually been bitten by dogs definitely ascertained to be rabid since the outbreak was discovered. Nearly all of them have received anti-rabic treatment at Paris or at Plymouth, and it is satisfactory that no human case of hydrophobia has so far occurred. In their last Memorandum to the local health authorities, dated Dec. 31st, 1918, the Local Government Board state that the Board of Agriculture take steps to secure that the names of all persons known to their officers or to the police to have been bitten by dogs known or suspected to be rabid are at once communicated to the medical officer of health of the district. That officer communicates direct with the medical department of the Local Government Board, through which he learns of the facts regarding the dogs which have been ascertained at the laboratories of the veterinary officers of the Board of Agriculture, and obtains any further information available to guide him in deciding whether anti-rabic treatment should be advised. Where this advice is necessary the arrangements for treatment are to be made by the medical officer of health by direct communication with the pathologist at Plymouth, in order that the course of treatment may be started as speedily as possible.

Annotations.

"Ne quid nimis."

THE ETIOLOGY OF LINGUAL CANCER.

IN his Bradshaw lecture on Cancer of the Tongue Mr. D'Arcy Power referred to the fact that it is almost entirely a human disease; it is always of one type; it is unknown in children; it is common in men, rare in women, and is not associated with any inherited predisposition to carcinoma. He gave an interesting description of the disease from the historical standpoint, pointing out that it did not become important surgically until the seventeenth century, the Greek, Latin, and Arabian writers on surgery hardly mentioning it, and so far as can be ascertained at present it is unknown to the Anglo-Saxons.

"The first definite notice of cancer of the tongue is the case of Ralph Freeman who died on March 16th, 1634, whilst serving the office of Lord Mayor of London. He suffered from secondary hæmorrhage and it was the opinion of the physicians and surgeons who were in attendance upon him that a mercurial course might have been of use at an earlier period of the disease. The second recorded case occurred in Germany, and was looked upon as a miraculous punishment for cursing the clergy. The story runs that 'lately a certain baron spoke abusively to all and sundry, but kept his most venomous shafts for the clergy and for those who devoted themselves to God's service. One day a holy brother of good repute whom he had just lashed said, "Your foul tongue has overlong deserved that punishment from an offended God which it will shortly receive." The baron rode off undismayed, but a few days later a small swelling began to grow at the side of his tongue. Little by little it increased in size until it became an inoperable cancer, and the baron, penitent and confessed, died miserably afflicted.' From the middle of the seventeenth century onwards cancer of the tongue became so frequent that it was no longer necessary to invoke a miracle for its production. At the present time cancer of the tongue is known to have occurred in one horse, three cats, and one dog. All these animals were aged, and in each the cancer was of the squamous-celled variety. It appears fair to assume, therefore, that lingual carcinoma has always occurred in men and domesticated animals; that originally in man it was no more frequent than it is now in animals; but that from the seventeenth century onwards it has increased out of all proportion in man, whilst the incidence has remained stationary in animals."

The returns of the Registrar-General were quoted in order to show the rate at which cancer of the tongue has increased in man. Dr. T. H. C. Stevenson, Superintendent of Statistics at Somerset House, writing in 1909, said that "the recorded mortality has increased amongst males by no less than 228 per cent. in 41 years. The increase, moreover, is entirely confined to the male sex." Mr. D'Arcy Power then considered the possible factors causing this increase, among which irritation had long been looked upon as important, and it has been suggested that pyorrhœa and dental caries have become more common. He thought that the virulence, but not the amount, of pyorrhœa seemed to have increased lately, whilst caries did not appear to be more frequent now than it was in some parts of England during the prehistoric period. Roman skulls found in England, he said, had nearly as many carious teeth as there are in the skulls of Londoners who died within the last 200 years. And if cancer of the tongue were the direct result of carious teeth the disease should have been as well known to the surgeons at Rome as it now is to us. But neither in Celsus nor in the Latin satirical poets is there any allusion to it. With regard to the question of syphilis being a predisposing cause, the lecturer gave, in discussing this point, an account of 169 persons who were

admitted to St. Bartholomew's Hospital with cancer of the tongue during the years 1909-1916.

Nine of the patients were women, the rest were men, or a proportion of 18 to 1; the true proportion, as shown by the returns of the Registrar-General, being 1 woman to 8 men. Of the women seven were married, one was unmarried, and the social state of the other is not mentioned. Of the seven married women, one gave a history of syphilis, two showed signs of syphilis, and one was a widow who had only one child alive out of five; the note adds, "She looks as if she drank." One woman had leucoplakia of the tongue at the age of 17, and stated that her father had suffered from an "abscess of the brain" which was cured by medicine. This was probably a gummatous meningitis. There was no history of syphilis, either acquired or inherited, in the other two married women. The unmarried woman—a nurse—said that her father died of aneurysm, and that she herself had suffered from an abducent paralysis which came on suddenly and was cured by medicine. None of the women smoked, but all had bad teeth.

In the case of the men 93 out of the 160 were syphilitic. 62 gave a history of syphilis, and the remaining 31 showed signs of the disease, the syphilis being invariably of long standing. Twenty-six patients stated definitely that they had never had syphilis, but one of these had suffered from gonorrhœa, and the blood of two gave a positive Wassermann reaction. Many of the patients had drunk to excess, but did not, as a rule, acknowledge that they had taken spirits freely.

A Wassermann test had only been performed 26 times; it was negative in 12 and positive in 6 cases; in 5 it was doubtfully negative and in 3 doubtfully positive. These results were compared with those obtained by Captain Arnold Renshaw, R.A.M.C., of the Manchester University Medical School, and Captain Archibald Leitch, R.A.M.C. (T.), of the Cancer Hospital, Brompton, and it was thought that the evidence brought forward pointed to a close association between syphilis and cancer of the tongue. The syphilis might be active, but it was more often quiescent or even extinct, the conclusion arrived at being that, as in some cases of tuberculosis, "syphilis made the bed upon which cancer is born." It appeared, further, that an increase in the number of deaths from lingual carcinoma had occurred after periods when mercury had temporarily fallen into disuse in the treatment of syphilis. Such insufficient treatment was the rule in the later years of Queen's Elizabeth's reign, when guaiacum, sarsaparilla, and the "vegetable" cures displaced the original mercurial methods; as also during the Regency period, when some of the Army medical officers nearly succeeded in abolishing the use of mercury; and, again, in the early Victorian era, when the value of potassium iodide was unduly exploited. Many of the patients whose cases were recorded at St. Bartholomew's Hospital stated voluntarily that they had only been treated with mercury for a fortnight or three weeks, after which they considered themselves cured.

Syphilis, Mr. Power concluded, could not be considered as more than a predisposing cause of cancer of the tongue, because lingual carcinoma occurred in animals. An exciting cause, therefore, must be looked for, and that cause ought to have become more prevalent during the last 50 years if the increase in cancer of the tongue was to be attributed to it. The cause must also be one which acts in men more than in women. He thought that the increased consumption of tobacco seemed to fulfil these conditions. Cancer of the tongue, he said, did not become frequent until some years after the introduction of smoking in the last quarter of the sixteenth century. The habit spread slowly during the seventeenth, eighteenth, and nineteenth centuries. Cigarettes were introduced about 1877, and from that time onwards the smoking of tobacco has steadily increased until it is now an almost universal habit with both sexes from adolescence onwards. Smoking acts in two ways as an irritant to the tongue, partly through the nicotine and partly by the increased heat in the mouth, which is measurable by the thermometer. In the latter respect it may bear the same relation to cancer that heat does in kangri cancer, where the thermal irritation appears to be a definite factor in the production of epithelioma. Although the predisposing and the exciting causes of cancer may be

known, the actual cause has yet to be discovered, but if two factors are recognised it ought not to be impossible to discover the third. It is theoretically possible to reduce cancer of the tongue to the subordinate position it occupied before the seventeenth century and which it still holds in the domestic animal, and this could be effected by a thorough treatment of syphilis in its initial stages. Persons who were being treated for syphilis should be told never to smoke, not to drink to excess, and to pay regular visits to the dentist. Such advice should be given whilst the patient is still under treatment, and should not be deferred until the tongue has become sore. Failure to follow this advice and a continuance of the treatment of syphilis on ineffective lines will be followed in all probability by a very large increase in the number of patients with cancer of the tongue. This increase should begin about 1950, and should affect women as well as men, for syphilis is now more widely spread amongst the younger generation than it has been for many years past, and both sexes smoke much larger quantities of tobacco than ever before.

MOTOR MECHANICS FOR CRIPPLES.

MOTOR mechanics is proving in the Dominions, as here, a popular subject of instruction for crippled soldiers on their way to become self-supporting workers. Mr. Douglas C. McMurtrie, director of the Red Cross Institute for Crippled and Disabled Men in New York City, writes that the trade is almost too popular in the Canadian schools. Practically every Canadian soldier, when asked to choose from among the various trades in which classes are held, selects automobile mechanics. Most of the men now have to be dissuaded from their intention or the supply of mechanics would soon far exceed the demand. Canada, England, Germany, and India amongst the belligerents are offering training courses in motor mechanics to disabled men of their own forces, and America is falling into line. At the large reconstruction hospital at Fort McHenry, for instance, automobile mechanism is taught, and one-armed or one-legged mechanics will be no new thing once the general public has accepted the principles of re-education. In British Columbia gasoline engine classes were organised soon after the wounded began returning from overseas. Vancouver, Victoria, Esquimalt and Westhaven provide instruction in motor mechanics. In Victoria the Military Hospitals Commission and the Board of Education together operate a fully-equipped motor repair-shop in which men who wish to become chauffeurs are taught. Men trained in this course conduct a well-patronised taxi-stand in the town. Those who wish a thorough course in motor mechanism are sent to Vancouver, and later to the new workshops at Esquimalt and Westhaven. The Commission has arranged for war cripples at Vancouver to be taught driving in the evening classes of an excellent automobile school. At this school any disabled soldier may attend the day classes free of charge. Men from other parts of British Columbia are kept in Vancouver on a maintenance allowance while receiving training. Courses are also given at the University of Saskatchewan, and at the Provincial Institute of Technology and Art in Calgary. In this country, as is well known, the workshop at Roehampton is fitted up as a model garage in charge of disabled men who, besides being skilled instructors, understand the special problems of the

war cripple. At Dusseldorf the course in automobile mechanics was established at the request of the motor repair-shop owners, who needed workmen and could not obtain able-bodied men. Within a very few months of its inception the pupils had successfully repaired 14 different types of motors. In India Queen Mary's Technical School in Bombay gives opportunity for the study of automobile mechanics by the crippled natives, whose imagination has been roused by this method of equalising their physical handicap.

THE NOTIFICATION OF ENCEPHALITIS AND POLIOMYELITIS.

To those who have made a study of epidemic disease the decision of the Local Government Board to make acute encephalitis lethargica notifiable is a source of very real pleasure. It is all to the good that the hands of the public health authorities should be strengthened in respect of this disease, and there is much significance in the fact that although it has been discovered so recently it is already included in the list of diseases dealt with under the Public Health Acts. The advantages of notification as the fundamental step in the elucidation of the problems of infectious disease in general appear now to have been fully recognised, and the arduous labour which attended the struggle to get acute poliomyelitis on the list is bearing fruit in another direction. Judging by past experience there is the possibility of a recurrence of encephalitis lethargica in the spring, and the medical profession will not be caught unprepared for the visitation. The general characters of the disease, at any rate in its more striking forms, have been brought prominently before the profession in our columns and elsewhere. With information of the occurrence of cases at their disposal the authorities will be able to coördinate research, and the discovery of the cause of the disease, which is the first step towards rational treatment, will be advanced.

SPANISH-AMERICAN MEDICAL FELLOWSHIP.

THE spirit of friendly coöperation has invaded medical circles on both sides of the Atlantic, and one of its latest developments is the proposed issue of a Spanish edition of the very ably edited *Journal of the American Medical Association*. The purpose of the issue is to promote the study of scientific medicine, and in so doing to further a closer international relationship between the great federation of English-speaking states in the North and the looser union of Spanish-speaking republics in the South. Last March President George E. Vincent, of the Rockefeller Foundation, approached the editor of the *Journal of the American Medical Association* with a suggestion on the subject, and at a subsequent meeting of the board of trustees of the journal the publication of a Spanish edition was authorised. The first number is arranged to appear early in the present month, and the issue will be continued, for the time being, twice a month. All that is of more general interest and permanent value in the weekly Chicago edition will appear in the Spanish issue. Some 2000 medical practitioners in Central and South America have been asked for their opinion as to the reception such a journal would meet with, and all the replies as yet received have been favourable. Up to the present Mexico and South America have been wont to turn to France and Germany for undergraduate and post-

graduate teaching, and to take from them their inspiration towards progress. This new venture may lead the scientific men generally of the American Continent to realise their identity of interest and to open up opportunities for interchange of knowledge and of the results of research in various fields. We do not construe it in the sense of a rigid application of the Monroe doctrine. Certain standard English text-books of medicine have already been translated into Spanish, and we should like to see this peaceful form of penetration continue and develop.

PARALYSIS AGITANS AND THE CORPUS STRIATUM.

It appears that we are within a measurable distance of an understanding of the pathology of this chronic nervous syndrome. In an interesting paper by Dr. J. Ramsay Hunt in the *Archives of Internal Medicine* (November, 1918) this writer records in full detail the morbid findings in two cases of paralysis agitans; in both the sole lesion was found to be a primary atrophy of the pallidal system of the corpus striatum. The corpus striatum in man is divided by the passage of the internal capsule into two structures, the caudate nucleus and the lenticular nucleus. The latter is subdivided into an external segment, the putamen, and an internal, the globus pallidus. The globus pallidus is older phylogenetically than the caudate nucleus and putamen (neostriatum). It is also distinguished from these structures histologically. The neostriatum contains two types of cells, a small type of ganglion cell of pyramidal form, and a large type of ganglion cell, the homologues in the corpus striatum of the Betz cells in the motor cortex; the globus pallidus contains only these latter large cell types. By the course of the fibres related to these two cell systems their functional significance can be inferred. The small-cell fibres end in the globus pallidus; they constitute a short association and inhibitory system for the corpus striatum, and atrophy of this system is the essential cause of Huntington's chorea (Hunt). The large-cell fibres, on the other hand, have a wider distribution; they extend to the optic thalamus, constituting the efferent pallidal system, and exert, through the red nucleus and substantia nigra, a regulating influence upon the extra-pyramidal motor system of the spinal cord. Lesion of this pallidal system results in paralysis agitans. The corpus striatum and the strio-spinal system are to be regarded as constituting a mechanism for the control and regulation of automatic and associated movements, paralysis of which results in the syndrome of paralysis agitans; in this sense it is to be distinguished from the other type of central palsy characterised by spastic paralysis, a paralysis here of isolated and discriminatory movements, and referable to damage of the pyramidal system.

The two cases recorded confirm these views as to the pathology of paralysis agitans. In the first, that of a man aged 56, who died of an intercurrent infection, there were found atrophic changes in the large motor cells of the neostriatum, with slight reduction of the medullary network of the globus pallidus and thinning of the strio-hypothalamic radiation. The second case showed atrophic changes in the large motor cells of the corpus striatum and other changes in the globus pallidus similar to those met with in the first case. There were no other evidences of central nervous involvement in either case. Dr. Hunt discusses the causation of the symptomatology. The rigidity and tremor

are referred to a loss of striatal inhibition, the corpus striatum controlling muscle tonus as does the cerebral cortex. When this inhibitory function is abolished hypertonicity results. The striated muscle has a double innervation—the anisotropic disc system controlled by the motor nerves, and the sarcoplasmic substance controlled by the sympathetic system. The former subserves the function of quick contraction; the latter, plastic function concerned in posture. It is suggested that there exist two distinct centres for the control of muscle tonus—one for contractile tonus, which regulates the anisotropic disc system, the other for the plastic tonus. Both centres are under the control of the pallidal system, and loss of this control may be indicated by tremor or rigidity according to the system involved.

THE FUTURE OF THE V.A.D.

Now that hostilities have ended and the women of the Voluntary Aid Detachments are being demobilised, the question arises as to how we can assist them in qualifying for some useful career. Many of them are women of the educated classes who have given up the work which they had already entered upon in order to help the country in its great need: others were living a life of leisure and amusement when the call came. All have answered nobly; in the one case careers have been cut short, in the other the women have become imbued with the ideal of a life of activity and of usefulness to their fellows such as would not have dawned for them had there been no "Great War." It is with the endeavour of helping these women that Lady Amptill, chairman of the Joint Women's V.A.D. Committee, has initiated a scholarship scheme, and the Joint Committee of the British Red Cross is contributing a sum of money "as a tribute to the magnificent work so generously done by V.A.D. members during the war." Various spheres of work are suggested, for which scholarships will be given which are likely to prove attractive to different types of mind. The list, which makes no pretence to be complete, includes: medicine; nursing (military, naval, and civil); district nursing; village nursing; midwifery; school nursing (elementary schools); nursery nursing; school matrons; physical culture; instructors of mental defectives; pharmacy; X ray assistants; dentistry; domestic science; institutional cookery; sanitary inspectors; health visitors; welfare supervisors; hospital almoners; and infant welfare workers. Many V.A.D.'s have given yeoman service in domestic capacities and have proved their worth as cooks. Those who have given their time to nursing and other work of a medical character may wish to continue along the same lines. For many years the conditions and prospects of a nurse's life have not in general been such as to attract the best class of woman. The hours are long, the work is arduous and exacting, the pay is poor, and the prospects are uninviting. Anyone can be, or call herself, "a nurse," there is no definite qualifying standard, and consequently the position, when attained, is to some extent spoiled of the honour which is its due. There has never before been such a harvest of well-bred, well-educated women for the hospitals to garner if they can. But infant welfare work, domestic science, teaching, and many other attractive occupations are competing. Is it too much to suggest that the nursing profession should take this occasion to put its house

in order? The Great Northern Hospital has just given a lead by raising the scale of remuneration to ward and theatre sisters. Another London hospital is planning its nursing on three shifts instead of two. But much more remains to be done before nursing becomes a career to which we shall gladly commend our daughters, instead of a self-sacrificing adventure which they themselves choose, and one fit only for altruists.

THE DEATH-RATE OF MENTAL DEFECTIVES IN INSTITUTIONS.

IN noticing the annual report of the Royal Earlewood Institution for Mental Defectives in a recent issue (THE LANCET, 1918, ii., 656) we commented upon the excessively high death-rate recorded at the institution during the year 1917. Calculated on the average number of residents, this rate amounted to 81.5 per 1000. The medical superintendent of the institution, Dr. Charles Caldecott, informs us that the high death-rate is the product of several causes. In the first place, a large number of patients were elected many years ago to be maintained in the institution for life, and although on any average expectation of life these patients would have died off some years ago, there are, in fact, 20 to 30 of them still alive, and the death-rate is therefore each year unduly loaded by these survivals. During 1917, 16 of the recorded deaths occurred amongst such "life" cases. In the second place, asylum populations have not escaped the epidemics of the last two years. During 1916 a severe epidemic of scarlet fever occurred with about 70 cases; in 1917 an epidemic of measles with a total figure of 150 cases. These two epidemics, in Dr. Caldecott's opinion, left the convalescents more liable to general diseases, especially tuberculosis, and the latter was, in fact, the cause of about one-half the deaths. Added to this the stringent regulations respecting the lighting in force during the latter part of the war necessitated the closing of windows and ventilators or the close curtaining of windows, with resulting lack of fresh air and its invigorating qualities. The rationing of staple articles of diet doubtless had an undue effect on the conservative taste of institution patients and tended further to undermine their constitutions. Accepting this analysis as true in measure of the high death-rate of mental defectives, it will be seen that part of it is apparent, part irremediable, and part—possibly a considerable part—due to removable causes, some of which have already been removed. As with statistics in general, careful sifting is required to bring out any useful lesson.

MEDICAL INFLUENZA VICTIMS IN SOUTH AFRICA.

IN South Africa, as elsewhere, doctors and nurses have been endeavouring to stem the tide of the influenza epidemic, and many have succumbed to the disease, their death in some cases having been caused or hastened by overwork. Dr. Charles Howard Spaulding, of Johannesburg, who had been working at high pressure for several weeks, refusing to relinquish his professional duties although advised to do so, died in October at the age of 51 years. He was an M.D. of Chicago, who went out to South Africa in 1892. James Alexander Thwaites, a surgeon, who died on Oct. 11th, was the son of a Cape Government surveyor, and was born at Beaufort West in 1870. He was educated at the South African College, Cape Town, qualified at Edinburgh, and

served as senior medical officer with Kitchener's Horse for two years during the Boer war. Dr. William Mortimer died of influenza at Potchefstroom on Oct. 24th. He was born at Port Elizabeth in 1864 and was educated at St. Andrew's College, Grahamstown, and Diocesan (Bishop's) College, Rondebosch. He entered the London Hospital Medical College in 1883, securing the Conjoint Diploma in 1887. He took a deep interest in public affairs, was town councillor in Potchefstroom from 1905-06, and again from 1907-09, and was elected Member of the Legislative Assembly for Potchefstroom in 1907. Lieutenant-Colonel H. S. van Zyl, who, at the time of his death, was in command of No. 2 General Hospital, Maitland, Capetown, was, as his name implies, of Dutch descent. He was medical officer to General Botha during the Boer War of 1899-1902, and had been on active service since the Boer rebellion of 1914. Dr. A. S. Kuny died of pneumonia at the New Somerset Hospital, Capetown, where he was one of the resident medical officers, on Oct. 17th. He was the son of Dr. Kuny, of Volksrust, Transvaal, and was 26 years of age. He qualified at Edinburgh in 1915, and had served in the R.A.M.C. in Flanders for two years before returning to the Cape last August. The medical men who remain have been terribly overpressed, and some who had retired have returned for the nonce to active practice. The Hon. Sir Thomas Smartt, a Member of the Legislative Assembly since the retirement of the late Sir Starr Jameson, and Leader of the Opposition in the Union South African Parliament, who qualified in 1878, has during the epidemic been carrying out inoculations at Stellenbosch. It is not alone the human population which has suffered in South Africa; baboons and monkeys also appear to have fallen victims. Farmers in the Hekpoort district state that hundreds of baboons have been found lying dead in the kloofs and along the roadside, whilst monkeys are reported to have succumbed in the Cape Province. Witch doctors are reported to have been kept busy, with what success does not appear. Some of the Orange Free State natives are refusing medicine and pinning their faith to their ancient methods. This is natural, as medical science has not in this field shown anything very striking to compete with necromancy and sorcery.

Sir John Goodwin's tribute to the temporary officers of the Royal Army Medical Corps will be found on p. 84.

SIX Hunterian lectures will be delivered at the Royal College of Surgeons of England on Phases in the Life and Work of John Hunter, by Professor Arthur Keith, Conservator of the Museum, at 5 P.M. on Mondays, Wednesdays, and Fridays, commencing Jan. 20th. The dates will be announced in our Medical Diary from week to week.

IN a further list of New Year Honours, announced as we go to press, are the names of three medical men upon whom a well-deserved Knighthood of the British Empire has been conferred—namely, Dr. Edward Napier Burnett, chairman of the Economic Committee of the Army Medical Department; Dr. G. Archdall Reid, F.R.S.E.; and Dr. William Hale White, chairman and consultant to Queen Mary's Royal Naval Hospital at Southend. Other appointments to the Order appear under the heading "The War and After" or will be given next week.

Correspondence.

"Audi alteram partem."

"HETERÆSTHESIA."

To the Editor of THE LANCET.

SIR,—In connexion with Major D. W. Carmalt Jones's paper, "Sensory Changes in the Diagnosis of Trench Fever," which appeared in THE LANCET of Oct. 5th, we think that our own observations on a somewhat similar phenomenon may be of interest. We originally found that in a case of Brown-Séquard paralysis the phenomenon of allocheiria occurred at segmental boundaries when one electrode of the faradic battery was drawn across the skin upon the side of the body which exhibited sensory changes. In this manner we were able to map the segmental areas upon the whole of the left side of the body from the level of the second thoracic segment downwards, but were unable to find any corresponding phenomenon upon the right side of the body. This latter fact and the precautions which we took negatived the possibility of "suggestion." Having found this phenomenon accidentally, we proceeded to look for similar phenomena in other conditions. We found that when the unipolar faradic electrode is drawn over the skin (a pin may be used with less satisfactory results) in certain neurological conditions the patient responds either by a movement or by speech when cutaneous lines (which seem to be segmental or radicular) are passed across. His response indicates that the apparent sensory value of the stimulus (which varies in locus but not in strength) changes as the electrode passes across the line. The change may be in either direction—increase or decrease. The conditions in which we discovered this phenomenon are: concussion of the brain with fracture of the base of the skull; concussion of the spinal cord from the graze of a live shell; true shell concussion. In these states the phenomenon is transient—disappearing in a few days or weeks.

In many individuals it is extremely easy to obtain the phenomenon by "suggestion" even when it is thought that suitable precautions are being taken to prevent this. The drawing of a line upon the skin with a blue pencil in itself suggests to the patient where the next change should be felt, and we have found in our practice that it is advisable to mark points of change with dots, and to pass haphazard from one part of the body to another, finally joining the dots with lines for permanent record by photography. Where a line of change is being investigated it is essential to start the electrode at different distances from the expected line and to move it at an even rate over the skin. After using every precaution we are certain that the phenomenon as it occurs in such cases is a true one, and not due to "suggestion."

We would like to propose the term "heteræsthesia" for the phenomenon. As the lines of change do not, in our experience, mark a constant variation in sensibility (for at one time the line of change may be one at which the sensation is apparently intensified, while at another time, the electrode being drawn in the same direction across it, the change may be one of diminution) it has occurred to us that the phenomenon may be due to the disturbance of a higher mechanism which normally tends to adjust the excitabilities of the spinal segments, and, when disturbed, may allow those excitabilities to have greater than normal variation amongst themselves.

We have had the advantage of controlling our results in a large number of cases, many of whom have had malaria, and can say definitely that it is not necessarily present in men who have had malaria without concussion. But we have not examined cases of malaria during the fever or immediately after it. We have to a certain extent relied on this phenomenon of "heteræsthesia" in the diagnosis of shell concussion.

It would be interesting to know what Major Carmalt Jones's experience is with regard to the relation of the phenomenon to the period of fever and with regard to the duration of the phenomenon after the fever has ceased. We hope that a short paper which we wrote last year on this phenomenon as it occurs in neurological cases will shortly appear in another journal.

We are, Sir, yours faithfully,

Neurological Department, B.S.F.,
Nov. 1st, 1918.T. GRAHAM BROWN.
R. M. STEWART.

ANTIMONY IN BILHARZIOSIS.

To the Editor of THE LANCET.

SIR,—I have read Mr. J. E. R. McDonagh's note in THE LANCET of Sept. 14th. Nothing is new in medicine, and I dare say that tartar emetic (antimony tartrate) has been used many times for bilharzia, especially in days gone by before tartar emetic fell into disrepute. I have not seen Mr. McDonagh's book.

In May, 1917, after making a trial of antimony tartrate by intravenous injection for leishmaniasis (kala-azar, espundia, tropical sore, all of which are found in the Sudan), and finding it, as other workers had found before, a specific, I began to try it for the *Schistosomum hæmatobium* (Bilharz), and found it equally successful, and we have since used it as routine treatment and have still the treatment under trial at the Khartoum Civil Hospital. I hold the same opinion about it as I did at first—that it is a specific cure for bilharziosis. My work was original, and has been, independent of anyone else's work and quite spontaneous, and I had never read of, or heard of, or dreamt of any other worker having before tried antimony for bilharzia.

Although I had written my paper considerably before I despatched it to THE LANCET on June 2nd, it was published on Sept. 7th, 1918. I have now had one and a half years' experience of cases under the treatment, and think it will prove a great benefit to the people of Egypt. If they can get rid of the scourge of bilharziosis the Egyptians will become a clear-complexioned, rosy-faced race. One of the most striking features of the treatment is the change from the muddy, sallow face to a healthy, pink, clear complexion. I intend to publish more observations on the treatment shortly, but there is no hurry.

I may say that antimony tartrate for bilharziosis is under trial at the Egyptian Army Military Hospital, Khartoum, and I hope that Major Innes, R.A.M.C. (T.), who is interested in the treatment, and who is carrying it out with the caution and patience and with all the splendid critical qualities of the Scottish race which have made its scientific work so valuable, will have something favourable to put on paper soon.

I am, Sir, yours faithfully,

J. B. CHRISTOPHERSON, M.D.

Director, Khartoum and Omdurman Civil Hospitals.
Khartoum, Sudan, Nov. 20th, 1918.

EPIDEMIC ENCEPHALO-MYELITIS AND INFLUENZA.

To the Editor of THE LANCET.

SIR,—It seems worth while, at the risk of being wearisome, to draw attention to the increasing volume of testimony that points to the essential unity of epidemic encephalo-mylitis (in the epidemiological sense at least) with epidemic influenza. In this connexion the recent paper by Dr. Smith Jelliffe,¹ and the remarks of Dr. Beates,² as well as the observations of Sir Thomas Horder³ concerning the present prevalence of poliomyelitis, are of very great importance. Professor Chartier⁴ has discussed, with delicate irony, the claims of "encephalitis lethargica" to be considered an autonomous affection, and hints, not obscurely, that it is really "*une variété symptomatique d'une infection générale telle que l'influenza*." In a paper read by me a week or two ago before the Section (of the Royal Society of Medicine) for the Study of the History of Medicine, I gave many historical records of epidemics of encephalitis, encephalo-mylitis, and poliomyelitis, definitely associated with epidemics of influenza. But though Brorström, in 1910, first showed the relation between poliomyelitis and influenza it is Dr. Hamer who, above all others, has insisted on the importance of recognising the epidemiological association between these various epidemic prevalences generally.

As Lombard, of Geneva,⁵ wrote many years ago:—

La grippe est souvent précédée par une constitution éminemment nerveuse, dont les caractères principaux sont de porter la trouble dans les fonctions du cerveau et des nerfs encéphaliques.

In 1837, too, the "apoplectic" forms of encephalitis on which Dr. Farquhar Buzzard has justly laid so much stress were observed by Récamier and others, while Gintrac, of Bordeaux, described in the clearest manner "epidemic stupor" in

¹ New York Medical Journal, 1918, ii., 757, 807.² Ibid., 922.³ THE LANCET, 1918, ii., 874.⁴ La Presse Médicale, Dec. 23rd, 1918, 660, 661.⁵ Gaz. Méd., 1833, 729, and 1837, 214.

children; all this occurring, in Malcorps' words, amongst the "prodromes nerveux" of the epidemic influenza of that year.

Surely then, as Chartier says, if "encephalitis lethargica" is to take place as an autonomous affection, "il serait important de fixer nettement les limites et les caractères différentiels de cette maladie."

I am, Sir, yours faithfully,

Harley-street, W., Jan. 3rd, 1919.

F. G. CROOKSHANK.

RESIDENTIAL TREATMENT FOR PREGNANT WOMEN SUFFERING FROM VENEREAL DISEASES.

To the Editor of THE LANCET.

SIR,—In an annotation on the Prevention of Syphilis among Infants in your issue of Dec. 28th last reference was made to work done by the London Hospital, Whitechapel, and the Thavies Inn Venereal Centre for Pregnant Women, and it was stated that the London Hospital Venereal Department and the Thavies Inn Venereal Centre provided the only residential treatment in the metropolis for pregnant women suffering from venereal disease.

We have been desired by the board of management of the London Lock Hospital to write saying that this is incorrect, as since May, 1918, the London Lock Hospital has had a large maternity department open and working at the Harrow-road institution. During the period from May to December, 1918, 68 married and unmarried pregnant women have been admitted and treated and 42 women delivered, of whom 20 were suffering from syphilis and 22 from gonorrhoea, and 43 babies have been born.

We are informed by Mr. Charles Gibbs, F.R.C.S., and Mr. Arthur Shillitoe, F.R.C.S., honorary surgeons at Harrow-road, that all our pregnant syphilitic patients have a full course of "606" before their confinements. The results are most gratifying, as a large proportion of these women give a negative blood test before confinement and are delivered of children with a negative reaction.

In conclusion we wish to state that intravenous injections of "606" have been given to expectant mothers and babies admitted to the Lock Hospital since February, 1916, and it must be noted that the figures given above only refer to the period May to December of last year.

We are, Sir, yours faithfully,

KINNAIRD,

Chairman of the Board.

J. F. W. DEACON,

Deputy Chairman of the Board.

J. ERNEST LANE,

Chairman of the Medical Committee.

London Lock Hospital and Rescue Home, Harrow-road,
London, W., Jan. 3rd, 1919.

*. We are glad to hear of 42 other women offered efficient treatment in their desperate extremity. But the need must be tenfold greater than the accommodation, and this was the main lesson we wished to draw.—ED. L.

ADVANCES IN THE TREATMENT OF FRACTURES.

To the Editor of THE LANCET.

SIR,—Several letters have appeared in the columns of *THE LANCET* under the above heading emphasising the great work carried out by Major M. Sinclair in his method of extension and immobilisation of fractures of the long bones. It may appear to be ungracious to offer any criticism when the results obtained are so good as far as the length and the alignment of the fractured bone are concerned, but in many cases treated by prolonged immobilisation by Major Sinclair's method there remains a considerable degree of limitation of movement in the joint below the fracture. In the case of the fractured femur this has been overcome by the method devised by Major Besley and subsequently modified by Major W. Pearson, by which the extension is made directly to the lower end of the femur by means of pointed callipers, whilst movement is made frequently in the knee-joint without any interference with the fracture. Major Sinclair's net-frame is of great advantage when, in addition to the fractured femur, there are wounds in the buttock, or when abduction is required, but the arrangement of the more recent fracture bed devised by Major

Pearson allows of an equally simple dressing, &c., without the disadvantages of a special and somewhat cumbersome apparatus.

However, the greatest credit must still be given to Major Sinclair as the originator of methods, even if certain modifications of these methods have been found more efficacious in some forms of fracture.

I am, Sir, yours faithfully,

R. H. JOCELYN SWAN,

Major, R.A.M.C.; Consulting Surgeon, Woolwich District.
Jan. 6th, 1919.

THE CAUSES AND INCIDENCE OF DENTAL CARIES.

To the Editor of THE LANCET.

SIR,—In his letter on this subject published in *THE LANCET* of Jan. 4th Dr. Harry Campbell states: "I have again and again referred to the prosaic fact that there are among the inhabitants of this country some 200 million carious teeth, as many alveolar abscesses (pyorrhoea alveolaris), and some 30 million root abscesses." I presume that Dr. Campbell will not object to furnishing some evidence of this "prosaic fact" (?) for the benefit of your readers, many of whom are (like myself) deeply interested in the subject.

I am, Sir, yours faithfully,

R. DENISON PHELEY.

Railway Approach, London Bridge, S.E., Jan. 6th, 1919.

THE PRACTICE OF THE ABSENTEE.

To the Editor of THE LANCET.

SIR,—I cannot understand Dr. F. R. Mallett's indignation with the letter of Dec. 28th, 1918, signed "Major, R.A.M.C. (T.C.)." I am a doctor in general practice who has been to the front and returned to practice. I find on my return that several of my former patients are being treated by professional brethren who remained at home; these patients are not asked if they wish to return to me. There being very little opposition, the doctors who remained at home charged high fees, frequently demanding the money before they left their houses. My midwifery cases who had "booked" the other doctors are not returned to me. New panel patients, who in the ordinary course would have come on my list, have been put on the lists of the doctors who remained, and every difficulty is put in the way of their coming to me.

The doctors who remained at home opened during my absence a surgery within half a mile of my house. It is still open. These tactics will not pay in the long run, but it is a little irritating to those who have undergone the hardships of active service and who have been under shell fire to hear so much about "the overwork" of those who stayed safely at home and who probably earned twice their usual incomes. I would suggest that these overworked gentlemen should join the R.A.M.C. for the demobilisation and so allow their brethren who have been to the front to come back at once and start their practices with less opposition.

I am, Sir, yours faithfully,

Jan. 6th, 1919.

TEMP. R.A.M.C.

To the Editor of THE LANCET.

SIR,—With reference to the correspondence in *THE LANCET* on the above subject, may I state my own case as I have just been demobilised after 20 months' service? I arranged with a neighbour to carry on in my absence, the receipts to be divided between us. There was very little panel (only 100), the rest being private work. The practice is an old-established one, and has never done less than £1000 per year. At the time of handing over there was a visiting list of 20 per day; when I returned I was given a list of six patients *only*, not six per day. During the whole of this time I have received exactly £42 from the private part of the practice and about an equal amount from the panel, which has, of course, steadily got less. My rent and rates are £75 per year, so that had the war continued a little longer I should have been compelled to either give up the house or file my petition.

However, I am so pleased to be back comparatively sound that I do not complain, and if I can only manage to get through this year without getting very much into debt I shall indeed be a happy man. I don't blame anyone, least of all the practitioner who has carried on for me, as

patients naturally go to whom they fancy, and, so long as human nature is as it is, will not always say that they are someone else's patients. Mine may be an extreme case, as upon one occasion I was officially reported killed in action and upon another died after being wounded.

I am, Sir, yours faithfully,

Jan. 6th, 1919.

DEMOLISHED.

PURULENT BRONCHO-PNEUMONIA ASSOCIATED WITH THE MENINGOCOCCUS.

To the Editor of THE LANCET.

SIR,—In your issue of Dec. 28th, 1918, Captain J. A. Glover publishes a note describing six cases of broncho-pneumonia. His article bears a title which is wholly misleading. Looking at the heading, and knowing that Captain Glover had charge of the C.-S. Fever Laboratory for the London District, one would expect to find on reading the article that he would bring forward proof of the meningococcus causing broncho-pneumonia. But he does not do so. He simply describes broncho-pneumonia occurring in six patients, three of whom undoubtedly "carried" the meningococcus in their naso-pharynx. Captain Glover quotes notes from Dr. T. H. Jamieson describing the six cases and stating

that "examination of the sputum showed pneumococci." Post-mortem examinations were done on two cases, yet nothing is stated concerning the bacteriology of the broncho-pneumonia found. Captain Glover then states that in his opinion the broncho-pneumonia was probably due to a mixed infection of pneumococci or Pfeiffer's bacillus and meningococci.

Captain Glover is entitled to have his opinion, but before it can be accepted by others he must bring forward proof. Although three out of six cases of broncho-pneumonia were found to be "carriers" of the meningococcus in their naso-pharynx, this is no proof that the broncho-pneumonia was due to this organism. The pneumococcus was found in the sputum in all the cases, and efforts to isolate the meningococcus from one case failed. Even had Captain Glover isolated the meningococcus from the sputum this would not exclude the naso-pharynx as the source. Further, Captain Glover gives no bacteriological proof whatsoever for bringing Pfeiffer's bacillus into the cases. We still await definite bacteriological proof that the meningococcus can cause pneumonia. Captain Glover has not supplied it, and we cannot therefore accept his opinion.

I am, Sir, yours faithfully,

Jan. 4th, 1919.

"Tar" includes all matter insoluble in water but soluble in CS₂. "Carbonaceous" includes all combustible matter insoluble in water and in CS₂. "Insoluble ash" includes all earthy matter, fuel, ash, &c. One metric ton per sq. kilometre is equivalent to: (a) Approx. 9lb. per acre; (b) 2.56 English tons per sq. mile; (c) 1 g. per sq. metre; (d) 1/1000 mm. of rainfall.

The personnel of public health authorities concerned in the supervision of these examinations and of the analytical work involved remains the same as published in previous tables. The analyses of the rain and deposit caught in the gauge at the Meteorological Office are made in THE LANCET Laboratory.

THE ROYAL INSTITUTE OF PUBLIC HEALTH.—A further course of lectures and discussions on "Public Health Problems under War and After-war Conditions" is being held in the lecture-hall of this Institute (37, Russell-square, London, W.C.1) on successive Wednesdays in January, February, and March at 4 p.m. The subjects include industrial hygiene, the influenza epidemic, clean milk, women and the Ministry of Health, the tuberculosis problem, and after-war reconstruction, and among the lecturers are Dr. T. Carnwath, Captain, R.A.M.C. (T.F.), Professor I. Walker Hall, Professor E. W. Hope, Dr. W. J.

O'Donovan, Mr. P. C. Varrier-Jones, Sir A. Newsholme, Sir Thomas Oliver, and Viscountess Rhondda. The next lecture, on Coal and National Health, will be given by Professor W. A. Bone on Jan. 15th, and the others will be duly announced in the Medical Diary from week to week.—An exhibit of organic arsenical preparations used in the treatment of venereal disease, as well as a striking collection of propaganda pamphlets and posters dealing with the anti-venereal campaign, is on view at the Institute. The latter has been presented to the Institute by Colonel Snow, of the Surgeon-General's Office, U.S. Army.

Obituary.

THOMAS BUZZARD, M.D. LOND., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO THE NATIONAL HOSPITAL FOR PARALYSIS AND EPILEPSY.

THE death occurred last week, at an advanced age, of Dr. Thomas Buzzard, the eminent neurologist. For some time Dr. Buzzard had retired from the practice of his profession owing to ill-health, but until nearly 80 he advised patients to their great benefit, and only two years ago came before the public with an admirable book of personal experiences in the Crimean War.

Thomas Buzzard was born in London in 1831, the son of a solicitor, and was educated at King's College School and the University of London. He left the school young and became apprenticed to a doctor in accordance with the then prevailing methods of entering the medical profession. After apprenticeship he proceeded to King's College Hospital, where his career as a student was successful, and he became house surgeon to Sir William Fergusson. Then came two remarkable opportunities for gaining terrible experience. First he worked in 1854 with John Snow and French in fighting the cholera epidemic in Soho; and in 1855 he went to the

THOMAS BUZZARD, M.D. LOND.

Crimean War, being appointed to the British medical staff of the Ottoman Army, attached to the headquarters of H.H. Omer Pasha. He was present at the siege of Sebastopol, at the second expedition to Kertch, and at the battle of Tchernaiia, and after the fall of Sebastopol he accompanied the second Turkish Army to the Caucasus and took part in the establishment and conduct of base hospitals at Trebizonde and Sinope. For these services he received the Crimean medal with clasp for Sebastopol, the Order of the Medjidie and the Turkish War medal. The story is graphically and modestly set out in his book "With the Turkish Army in the Crimea and Asia Minor: A Personal Narrative," which was published by John Murray in 1916, with illustrations by the author.

On his return from the Crimea he resumed his studies and with such success that he became university medical scholar and later gold medallist in surgery. He graduated M.B. in 1857, and though his displayed and personal bent at the time was strongly towards surgical work he went into general practice as doctor to the St. Luke's district of St. James's parish. Here he remained for some six years, adding to an already great experience considering his age, that first-hand knowledge of life, men, and

manners which made him a practical psychologist as well as a learned clinician. At this time he developed a gift which proved very valuable to him in his after-career. He employed his intimate acquaintance with certain sides of large affairs, as well as of the working life of the lower strata of society, in journalism, turning to writing for the press as a congenial task and an obvious method of adding to resources until private patients came. In 1863 he cut loose from his official work as a parish doctor and started in consultant practice in Green-street, Park-lane. For some time he was regularly on the staff of the *Daily News*, for which paper he had acted as correspondent during the Crimean War, and he also joined the staff of THE LANCET. A feature of this paper at the time was a department entitled the "Mirror of Hospital Practice," the articles which appeared under this title being notes written on the spot by a representative of the paper who was present at the various operating theatres of London. At this time operations were infrequent and were performed at the various hospitals only on certain days of the week and on certain hours of those days. Buzzard's work as a contributor to the "Mirror of Hospital Practice"—this, it may be said, is his own statement—first brought him into touch with the National Hospital at Queen-square, and provoked his interest in neurology and started also his lifelong and intimate friendship with Hughlings Jackson. He was shortly elected to the staff of the hospital, and here, while his main interest in neurology was essentially clinical, he never neglected the pathological side and, indeed, was one of the first to recognise the relationship of bacteriology to neurological problems. Perhaps his chief contributions to our medical knowledge had reference to the discrimination between organic and functional disorders especially in reference to disseminated sclerosis. This line of work was prompted by frequent consultation upon his gynaecological patients with William Playfair, to whom a great many women had recourse who, rightly or wrongly, were supposed to be the subjects of hysteria. Buzzard's book, entitled the "Simulation of Hysteria by Organic Disease," was the outcome of the investigation of such cases, and it was along these lines of medicine that he deservedly made his European reputation. Although he was only attached to one hospital, and that a neurological institution, his knowledge of general medicine saved him from taking narrow or loose views of his patients. He was able to devote a large part of his time to bedside study because he served one hospital only, while he made the most of the wonderful opportunities afforded him at Queen-square. So far was he from being merely a specialist that, in a way, the range of his interests and their large clinical nature probably obscured his scientific position, and to no other reason can we attribute the fact that a man, much of whose work was so original as well as so fruitful of work in others, should never have been invited to become a Fellow of the Royal Society. He was at different times President of the Clinical, Harveian, and Neurological Society, and Foreign Corresponding Member of the Société de Neurologie de Paris.

Although Buzzard wrote with ease and distinction he was not a voluminous author. He contributed the articles on hysteria, sciatica, and tic to "Quain's Dictionary of Medicine," and wrote in the journal of the Ophthalmological Society, to these columns, and to the columns of the *British Medical Journal* upon various neurological subjects. His record of his Crimean experiences, to which we have alluded, shows that had the idea appealed to him he could have easily gained a large public as a writer. He was a good public speaker and had also considerable artistic gifts, was an accomplished painter in water colours, etched with some success, and exhibited on several occasions. He was devoted to travel, and in his later life made many sea voyages, garnering impressions and sketching.

Dr. Buzzard married in 1869 Isabel, daughter of the late Joseph Wass, by whom he had two daughters and four sons, one of whom is Dr. E. Farquhar Buzzard. On the occasion of his marriage he removed from Green-street to 56, Grosvenor-street, where he remained over 20 years, finally moving to 74, Grosvenor-street, where he died. His domestic life was ideally happy, and the loss of his wife, who died in 1901, was a blow which he felt during the remainder of his days. He died very peacefully after a short and mild attack of influenza.

**SIR WILLIAM BARTLETT DALBY, M.A. CANTAB.,
F.R.C.S. ENG.,**

CONSULTING AURAL SURGEON, ST. GEORGE'S HOSPITAL.

WE announced last week the death, at an advanced age, of Sir William Bartlett Dalby, who was a well-known aural surgeon in London a generation ago, as well as a regular contributor to the literature of these subjects in the coöperative medical treatises of the day.

Sir William Dalby was born at Ashby-de-la-Zouche in 1840 and was educated at Sidney Sussex College, Cambridge, and the medical school of St. George's Hospital. He graduated in Arts at Cambridge in 1863, proceeding to the M.B. degree in 1866, and for a time went into general practice at Chester. He soon, however, returned to London, became a Fellow of the Royal College of Surgeons of England in 1870, and decided to specialise in diseases of the ear. He was fortunate in becoming assistant to that singular and famous man James Hinton, who was then practising as an aural surgeon in Savile-row. Hinton died in 1874, but during his last illness Dalby took entire charge of his practice, and on the death of his chief acquired the house and connexion from Hinton's executors. Such a sale of consultant practices was in those days not unusual, though soon afterwards the proceeding was regarded askance, and, as a matter of fact, Hinton himself had purchased the practice and premises in Savile-row from the eminent aural surgeon Toynbee. With such an apprenticeship and such a start Dalby's success was assured, but he soon made a real and original departure, with which his name is not now associated as closely as it should be, for at the time he was a pioneer. No doubt he acquired much both of his theories and his information from Germany, but to Dalby's credit it should be remembered that his advocacy of the instruction of the born-deaf child by lip-reading has transformed a large number of persons afflicted with a grave disability into perfectly capable, competent, and happy citizens. It was for work in this connexion that Dalby received his knighthood in 1886.

During the 20 years between 1875 and 1895 Dalby had a very large practice, and his opinion was sought from all parts of the kingdom. He published a series of lectures on diseases and injuries of the ear, and wrote articles on the same subject in Holmes's "System of Surgery" and Quain's "Dictionary of Medicine," while his "Short Contributions to Aural Surgery" ran through three editions, and deserved its popularity by its wide practical information and its pleasant writing. Dalby was not in any sense a good operating surgeon, and though he may have neglected steps to keep abreast with the surgical operative procedure of his day, it must be remembered that cranial surgery, when he was at the head of his specialty, was in its infancy. As aural surgeon to St. George's Hospital his outpatient clinics were well attended by the students who learned such science and technique as were then generally accepted, and who were often profoundly amused by Dalby's shrewd, humorous, caustic, but kindly attitude towards his patients. Many of the leaders of medicine and surgery of Dalby's day found themselves in an unstable position by the enormous development in operative surgery following on the discovery of Listerian doctrines and the perfection of methods of administering anæsthesia; and undoubtedly Dalby was embarrassed as a man of science by the date of his active work. But he was the main link between the periods of non-operative and operative aural surgery, and the developments in aural surgery following upon the work notably, among others, of Sir William Macewen and Sir Charles Ballance, he wisely determined not to attempt to follow practically. He never performed any complete mastoid operation, leaving such procedures to a younger generation.

Dalby was essentially a man of the world. His elaborately groomed appearance was more that of a leisured country gentleman than that of a leader in a highly technical surgical specialism. His wise if cynical attitude towards life was well displayed in the "Letters of Dr. Chesterfield," which he contributed towards the end of his professional career to the *Cornhill Magazine*, and from a worldly point of view most of what he said wittily in those letters cannot be controverted. He had a host of friends, was a member of the Athenæum, Carlton, and Garrick Clubs, was especially popular among artistic and literary people, was a well-read

Shakespearian scholar, and a keen and constant attendant at the theatres. He rode, shot, fished, and yachted at various periods of his life, out of which he derived far more amusement than most medical men contrive to obtain.

Sir William Dalby married Hyacinthe, the daughter of Major Edward Wellesly, by whom he had two sons and three daughters. His elder son was drowned in a boating accident at Sandhurst; his second son, a soldier, survives him and was wounded in the present war. He leaves also a widow and three married daughters.

REGINALD PERCY COCKIN, M.D. CANTAB.,

ASSISTANT MEDICAL ENTOMOLOGIST, LONDON SCHOOL OF TROPICAL MEDICINE, ETC.

WE regret to record the death of Dr. R. P. Cockin on Dec. 9th, 1918, at Kensington. Dr. Cockin was born at Hull in 1879 and studied at Cambridge, taking his M.A. degree in 1906 and his M.D. in 1913. His medical studies in London were carried out at the London Hospital. After graduating in medicine he acted as casualty house surgeon of Hull Royal Infirmary. Entering the West African Medical Service, he was appointed district surgeon of Okigwi in Southern Nigeria, and later on medical officer of the Niger Cross River Expedition in 1908-1909. In 1910 he was transferred to Cyprus, acting there as a district medical officer and examiner under the Pharmacy Act. In 1913 he was posted to Grenada, West Indies, where he was resident surgeon to the Colony and Yaws Hospitals, and also did bacteriological work. After this he joined the staff of the London School of Tropical Medicine. In 1915 he was appointed a temporary lieutenant in the Royal Army Medical Corps, and went to Egypt with Colonel R. T. Leiper and Captain J. G. Thomson, where he helped in the investigation of bilharziasis. Owing to ill health he had to resign his commission as captain, and resumed his duties at the London School of Tropical Medicine. When the special venereal clinics were formed in London by the Local Government Board, Dr. Cockin started the one at the Albert Dock Hospital, acting as its director.

Dr. Cockin's death in early middle age is a loss to the medical profession, for he was a man of wide experience and high scientific attainments.

URBAN VITAL STATISTICS.

(Week ended Jan. 4th, 1919.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality, which had declined from 36.5 to 17.8 in the five preceding weeks, rose to 16.1 per 1,000. In London, with a population slightly exceeding 4,000,000 persons, the death-rate was 18.6, or 2.8 per 1,000 above that recorded in the previous week; among the remaining towns the rates ranged from 7.3 in Bristol, 8.8 in Oxford, and 9.0 in Ilford, to 23.2 in Gateshead, 25.4 in Sunderland, and 27.0 in Liverpool. The principal epidemic diseases caused 147 deaths, which corresponded to an annual rate of 0.5 per 1,000, and included 51 from infantile diarrhoea, 49 from diphtheria, 17 from whooping-cough, 14 from measles, 11 from scarlet fever, and 5 from enteric fever. The deaths from influenza, which had steadily declined from 7557 to 581 in the eight preceding weeks, further fell to 441, and included 66 in Liverpool, 65 in London, 19 each in Bristol and Birmingham, and 14 each in Manchester and Leeds. There were 3 cases of small-pox, 1062 of scarlet fever, and 1116 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital; the two latter were 39 below and 11 above the respective numbers remaining at the end of the previous week. The causes of 61 deaths in the 96 towns were uncertified, of which 12 were registered in Liverpool, 8 in Birmingham, 6 in Manchester, and 3 each in Nottingham, Blackpool, South Shields, and Gateshead.

Scotch Towns.—In the 16 largest Scotch towns with an aggregate population estimated at 2,500,000 persons, the annual rate of mortality was 16.7, against 14.8 and 16.1 per 1,000 in the two preceding weeks. The 324 deaths in Glasgow corresponded to an annual rate of 15.1 per 1,000, and included 6 from whooping-cough, 3 each from diphtheria and infantile diarrhoea, and 1 from measles. The 145 deaths in Edinburgh were equal to a rate of 17.8 per 1,000, and included 3 from whooping-cough, 2 from diphtheria, and 1 from scarlet fever.

Irish Towns.—The 182 deaths in Dublin corresponded to an annual rate of 23.4, or 3.0 per 1,000 above that recorded in the previous week, and included 2 from whooping-cough and 1 from infantile diarrhoea. The 133 deaths in Belfast were equal to a rate of 17.3 per 1,000, and included 2 from infantile diarrhoea and 1 from measles.

PRIZES of the Paris Académie des Sciences have been awarded as follows: Prix Montyon (physiology) to M. Stephen Chauvet, for a work on Pituitary Infantilism; Prix Lallemand to MM. Henry Landot and Henry Langier, for work on the electrical stimulation of nerves; Prix L. Las Caze to Professor Raphaël Dubois, of Lyon, for contributions to physiology.

The War and After.

MEDICAL DEMOBILISATION.

Sir John Goodwin, the Director-General, Army Medical Service, states that owing to the very urgent requests of the National Service Ministry, the Civil Hospitals, and the Insurance Commissioners, it has been found necessary to demobilise immediately a large number of R.A.M.C. officers to meet the pressing needs of the civil population. The Director-General greatly regrets that, owing to the shortness of the notice, he has not found it possible to see or write personally to all officers on demobilisation, but he would like to assure them of his sincere gratitude for their valuable services and of his warm recognition of the very heavy personal sacrifices made by many of them in their desire to serve their country and to render assistance to the sick and wounded of the Army.

THE SCHEME OF THE CENTRAL MEDICAL WAR COMMITTEE FOR DEMOBILISATION.

A meeting of the Central Medical War Committee was held on Jan. 8th, at which the scheme for demobilisation of medical men was discussed. A circular letter having been sent by the National Insurance Commissioners to the Insurance Committees in England and in Wales, as well as to individual doctors, Sir Robert Morant addressed the meeting to point out that he disclaimed any desire to act in opposition to the Central Medical War Committee. His department, however, he said, must consider first the needs of the civilian population, and he added that, of the 12,000 medical men on the panel before the war, at least one-third were absent, either with the colours or owing to the inevitable wastage of four and a half years; figures which meant that the pre-war standard of medical practice could not be maintained.

The Ministry of National Service having sent out a questionnaire to be completed by medical officers holding commissions in any of the Services, Sir James Galloway explained to the Central Medical War Committee the present position. He indicated that the figure of 1400 had been mentioned as representing the number of practitioners whose return from the Services was urgently required, and that this number was now within sight. The War Office, he said, had found less difficulty than had been anticipated in releasing men, large military hospitals were to be immediately demobilised, and no less than 18,000 V.A.D. beds had already been dismantled.

General Principles of the Scheme.

The scheme for priority of release drawn up by the Central Medical War Committee is intended to apply to the demobilisation on personal and professional grounds of all medical officers serving temporarily with the Forces. It has received the approval of the Ministry of National Service; but as it has not yet been adopted by the Scottish Medical Emergency Committee, it applies at present to practitioners from England and Wales only. The following notes will serve to indicate the principles upon which the scheme is based.

The main object has been to devise a plan which is at once simple, capable of amendment at any time, and easily explained to those concerned. As soon as provision is made for areas in which the medical service has been dangerously depleted it is proposed that the demobilisation of medical officers shall proceed along lines which take into account (a) length of service; (b) age; (c) special personal hardships in connexion with their practices; and (d) family responsibilities. For this purpose the names of those over the age of 30 on Nov. 11th, 1918, will be classified in the following groups: (1) Those who were mobilised at the outbreak of war; (2) those who have served over three years; (3) those who have served between two and three years; (4) those who have served between one and two years; (5) those who have served less than one year. Each group will be divided into four subgroups arranged according to age.

The data for this primary grouping are readily obtainable, definite in character, and easily tabulated; but other factors, less easily tabulated, affecting some officers, must also be taken into account. Information which will be at the disposal of the Central Medical War Committee will enable it to take these special factors into consideration, and then, if necessary, to shift the position of an officer into a different

group from that in which the primary classification has placed him. In this process the following points will be taken into account: (1) Whether he is married or single, and the size of his family, if any; (2) if all the members of a partnership are away, or if the practice is single-handed; (3) his paid appointments (panel or otherwise), if any; whether such appointments are whole-time; and whether they have been kept open for him.

Special claims on financial or other grounds, which are not taken into account in the above method of classification, may be submitted to the Committee for special assessment.

The scheme is as follows:—

PART I.—Men over 30 Years of Age at Date of Armistice—i.e., Men Born on or before Nov. 11th, 1888.

(i.) The following points will be awarded on the grounds of length of service and age:—

| Men mobilised at the outbreak of war (R.N.V.R., R.N.E., R.A.M.C.(T.), & R.A.M.C.(S.R.)): | Points. | Men with over 3 years' service: | Points. |
|--|---------|---------------------------------|---------|
| Over 45 | 30 | Over 45 | 28 |
| 40-45 | 29 | 40-45 | 25 |
| 35-40 | 28 | 35-40 | 24 |
| 30-35 | 27 | 30-35 | 23 |
| Men with over 2 years' service: | Points. | Men with 1 year's service: | Points. |
| Over 45 | 22 | Over 45 | 18 |
| 40-45 | 21 | 40-45 | 17 |
| 35-40 | 20 | 35-40 | 16 |
| 30-35 | 19 | 30-35 | 15 |
| Men with less than 1 year's service: | Points. | | |
| Over 45 | 14 | | |
| 40-45 | 13 | | |
| 35-40 | 12 | | |
| 30-35 | 11 | | |

(ii.) The following points will be added or subtracted in respect of the following modifying conditions:—

- (1) If in whole-time salaried post, subtract 6 points.
- (2) If with no paid appointment or N.H.I. work, add 3 "
- (3) If in single-handed practice, add 3 "
- (4) If all members of partnership are on service, and no member of the partnership is otherwise entitled to more than ... points, add, in case of one partner 4 "
- (5) If married, add 4 "
- (6) If dependents, children or otherwise, 1 point for each dependent up to a maximum of 4 "

(iii.) Additional points may be awarded in respect of financial or other circumstances of an exceptional character which justify a claim to a higher order of priority than that determined by the foregoing provisions. The award of any such additional points would be the subject of special assessment by the Committee, and any man who deems that he has suffered special hardship on such grounds should apply to the Committee for a special consideration of his case on the facts.

(iv.) The order of priority of men of 30 and over shall be according to the net number of points accruing to each man under this part of the scheme, men with a greater number of points ranking before men with a less number of points.

PART II.—Men under 30 Years of Age at Date of Armistice—i.e., Men Born after Nov. 11th, 1888.

(v.) The order of priority determined under Part II. shall be in continuation of the order of priority determined under Part I.

(vi.) The order of priority of men under 30 years at the date of the armistice shall be according to their age, the older before the younger, no priority being, however, accorded as between men born in any one calendar year.

Provided that, in the event of the Central Medical War Committee deciding, upon a special application, that financial or other circumstances exist of an exceptional character which justify a claim by the applicant to a higher order of priority than that accorded under the foregoing provisions, the Committee may award that the applicant should be classed either on a level of priority (under Part II.) with men born in a specified earlier calendar year, or on a level of priority with men entitled to a specified number of points (under Part I.).

THE CASUALTY LIST.

The names of the following medical officers appear among the casualties announced since our last issue:—

Died.

Capt. J. S. Martin, R.A.M.C., was educated at Edinburgh and at St. Thomas's Hospital, London, and qualified in 1895. He held appointments at the Rotherham Hospital and at the Royal Infirmary, Edinburgh, and prior to joining up was in practice at Leigh, Lancs., where he was honorary surgeon to the local infirmary.

Surg. J. M. Pickthall, R.N., qualified in Edinburgh in 1885. He practised in Cornwall and in the Channel Islands, and was latterly surgeon on the Hospital Ship *Oxfordshire*, and the cable ship *Britannia*.

Capt. F. I. Mackinnon, R.A.M.C., qualified at Edinburgh in 1883, and was in Damascus when he joined up for war service. He died at Alexandria from pneumonia.

Capt. W. F. Luton, Canadian A.M.C.

Wounded.

Lieut. A. J. Abreu, I.M.S.

Capt. G. A. Khan, I.M.S.

THE HONOURS LIST.

The following awards to and promotions of medical officers for services at home in connexion with the war or for valuable services in the indicated spheres of operations are announced:—

Services at Home.

K.C.B.—Maj.-Gen. G. J. H. Evans, C.B.; Lt.-Gen. T. H. J. C. Goodwin, C.B., C.M.G., D.S.O., K.H.S., A.M.S.
K.C.M.G.—Maj.-Gen. W. W. Pike, C.M.G., D.S.O., A.M.S.; Temp. Col. J. Atkins, C.M.G., A.M.S.

C.M.G.—Col. H. A. Chisholm, Canadian A.M.C.; Temp. Col. (Hon. Surg.-Gen.) O. S. Ryan, Australian A.M.C.; Lt.-Col. F. Marshall, Australian A.M.C.; Col. B. J. O'Neill, D.S.O., N.Z.M.C.

K.C.B.E.—Temp. Hon. Col. J. L. Thomas, C.B., C.M.G.; Col. H. B. Bruce-Porter, C.M.G., A.M.S. (T.F.).

C.B.E.—Lt.-Col. C. W. Cathcart, R.A.M.C. (T.F.); Col. T. H. M. Clarke, C.M.G., D.S.O., A.M.S.; Col. G. Dansey-Browning, A.M.S.; Lt.-Col. Sir J. Payner, Bart., R.A.M.C. (T.F.); Col. R. Jennings, K.H.S., late A.M.S.; Maj. H. J. Neilson, late R.A.M.C.; Temp. Hon. Maj. H. S. Souttar, R.A.M.C.

O.B.E.—Col. W. H. Bull, V.D., A.M.S. (T.F. Res.); Maj. J. J. Coy, R.A.M.C. (T.F. Res.); Capt. R. Johnson, R.A.M.C. (T.F.); Lt.-Col. J. R. Mallin, late R.A.M.C.; Dr. Adeline Roberts, Q.M.A.A.O., Recruiting Medical Controller; Bt. Col. O. J. W. Tatham, ret. pay, late R.A.M.C.; Capt. J. S. White, R.A.M.C. (S.R.).

M.B.E.—Temp. Capt. J. N. Martin, R.A.M.C.

C.B.E.—Col. G. D. Farmer, Canadian A.M.C.; Col. J. Stewart, Canadian A.M.C.

O.B.E.—Capt. (acting Maj.) J. R. Goodall, Canadian A.M.C.; Lt.-Col. R. Ralke, Canadian A.M.C.; Lt.-Col. A. A. Smith, Canadian Army Dental Corps; Maj. (acting Lt.-Col.) A. W. Winnott, Canadian Army Dental Corps.

C.B.E.—Lt.-Col. (temp. Col.) M. McWhae, C.M.G., Aust. A.M.C.; Col. H. C. Mauley, C.M.G., Aust. A.M.C.

O.B.E.—Maj. P. T. Beamish, Aust. A.M.C.; Maj. J. H. Down, Aust. Army Dental Corps; Lt.-Col. B. M. Sutherland, Aust. A.M.C.; Maj. G. C. Willocks, M.C., Aust. A.M.C.; Lt.-Col. C. Yeatman, Aust. A.M.C.

C.B.E.—Maj. (temp. Lt.-Col.) W. M. Macdonald, N.Z.M.C.; Lt.-Col. H. J. McLean, N.Z.M.C.

O.B.E.—Maj. A. J. Brewis, N.Z.M.C.; Maj. W. Bruce, N.Z.M.C.

C.B.E.—Temp. Lt.-Col. B. N. Thornton, O.B.E., S.A.M.O.

O.B.E.—Temp. Maj. M. G. Pearson, S.A.M.C.

To be Brevet Colonel.—Lt.-Col. P. S. O'Reilly, C.M.G., R.A.M.C.; Lt.-Col. Sir J. G. Rogers, K.C.M.G., D.S.O., ret. pay (late A.M.S.).

To be Honorary Colonel.—Lt.-Col. W. H. W. Elliot, D.S.O., ret., I.M.S.

To be Brevet Lieutenant Colonel.—Temp. Maj. F. S. Brereton, ret. (late R.A.M.C.); Temp. Maj. G. P. Humphrey, R.A.M.C.

To be Brevet Major.—Temp. Capt. R. Bruce-Low, R.A.M.C.; Capt. (acting Maj.) A. A. Jubb, R.A.M.C. (T.F.); Capt. (acting Maj.) A. T. J. McCreery, M.C., R.A.M.C.; Temp. Capt. W. J. Tulloch, R.A.M.C.

Operations in Egypt.

C.B.—Temp. Lt.-Col. H. L. Eason, C.M.G., R.A.M.O.

C.M.G.—Lt.-Col. (temp. Col.) E. P. Sewell, D.S.O., R.A.M.C.

C.B.E.—Temp. Col. C. C. Choyce, R.A.M.C.; Lt.-Col. (temp. Col.) C. Garner, late R.A.M.C.

O.B.E.—Capt. R. Brereton, R.A.M.C. (T.F.); Temp. Capt. F. H. Diggle, R.A.M.C.; Maj. W. Dyson, R.A.M.C. (T.F.); Maj. (acting Lt.-Col.) W. P. Ellis, R.A.M.C.; Temp. Capt. W. W. Forbes, R.A.M.C.; Temp. Capt. N. S. Gilechrist, R.A.M.C.; Maj. F. Grace, R.A.M.C. (T.F.); Capt. D. L. Graham, I.M.S.; Capt. J. Inglis, R.A.M.C. (T.F.); Capt. T. F. Kennedy, R.A.M.C.; Maj. (acting Lt.-Col.) J. W. Mackenzie, R.A.M.C. (T.F.); Capt. (acting Maj.) L. M. V. Mitchell, R.A.M.C. (T.F.); Temp. Capt. C. W. Smith, R.A.M.C.; Lt.-Col. G. R. F. Stammers, R.A.M.C.; Maj. G. C. Taylor, R.A.M.C. (T.F.); Maj. F. B. Treves, R.A.M.C. (T.F.); Capt. (temp. Lt.-Col.) P. S. Vickerman, R.A.M.C. (S.R.); Capt. (acting Maj.) A. P. Watson, R.A.M.C. (T.F.); Temp. Lt. K. R. Madan, I.M.S.

M.B.E.—Capt. J. Green, R.A.M.C. (T.F.).

C.B.E.—Lieut.-Col. I. (temp. Col.) G. P. Dixon, Aust. A.M.C.

O.B.E.—Lt.-Col. O. B. Blackburn, Aust. A.M.C.; Maj. N. H. Fairley, Aust. A.M.C.; Lt.-Col. (temp. Col.) R. Fowler, Aust. A.M.C.; Lt.-Col. (temp. Col.) J. C. Storey, Aust. A.M.C.

M.B.E.—El Yuzbashi Halim Hendi Sulman Shoucair, Egyptian Army M.C.

To be Brevet Colonel.—Lt.-Col. E. H. Powell, D.S.O., R.A.M.O.

To be Brevet Lieutenant Colonel.—Maj. (acting Lt.-Col.) A. W. Gibson, R.A.M.O.

To be Brevet Major.—Temp. Capt. P. H. Bahr, D.S.O., R.A.M.O.

Distinguished Service Order.—Maj. E. B. Austen, att'd. R.A.M.C.; Maj. L. A. Avery, R.A.M.C. (T.F.); Maj. (acting Lt.-Col.) J. Evans, R.A.M.C. (T.F.).

Military Cross.—Capt. (acting Maj.) J. H. Beverland, R.A.M.C. (S.R.); Temp. Capt. G. J. O. Ferrier, R.A.M.C.; Capt. (temp. Maj.) I. P. Harris, R.A.M.C. (T.F.); Capt. W. F. T. Haultain, R.A.M.C. (S.R.); Temp. Lt. B. H. Kamakaka, I.M.S.; Capt. (acting Maj.) L. Milton, R.A.M.C.; Temp. Capt. H. J. Rae, R.A.M.C.; Temp. Capt. F. O. Robbs, R.A.M.C.; Capt. (acting Maj.) A. B. P. Smith, R.A.M.C.; Capt. C. Anderson, Aust. A.M.C.

Operations in Italy.

C.M.G.—Lt.-Col. (temp. Col.) S. A. Archer, R.A.M.C.; Lt.-Col. (acting Col.) H. A. L. Howell, R.A.M.C.; Lt.-Col. J. W. West, R.A.M.C.; Lt.-Col. C. H. Funnell, R.A.M.C.

O.B.E.—Capt. (acting Maj.) T. D. Inch, M.C., R.A.M.C.; Capt. A. Picken, R.A.M.C. (S.R.); Capt. (acting Maj.) J. D. Wells, R.A.M.C. (T.F.).

To be Brevet Colonel.—Lt.-Col. H. Chopping, C.M.G., R.A.M.C.

To be Brevet Lieutenant Colonel.—Maj. (temp. Lt.-Col.) J. G. Bell, D.S.O., R.A.M.C.

To be Brevet Major.—Capt. (acting Col.) W. G. Wright, D.S.O., R.A.M.C.

Distinguished Service Order.—Capt. (acting Lt.-Col.) B. A. Broderick, M.O., R.A.M.C. (T.F.); Temp. Capt. W. Mackenzie, R.A.M.C.

Military Cross.—Temp. Capt. A. H. Macklin, R.A.M.C.

Operations in Salonika.

C.B.—Temp. Col. A. G. Phear; Capt. and Bt. Maj. (temp. Col.) R. H. Kelly, R.A.M.C. (T.F.).

C.M.G.—Lt.-Col. C. B. Martin, R.A.M.C.

O.B.E.—Temp. Capt. (acting Maj.) D. I. Anderson, R.A.M.C.; Temp. Capt. J. C. M. Bailey, R.A.M.C.; Temp. Capt. (acting Maj.) G. V. Bakewell, R.A.M.C.; Capt. (acting Maj.) T. Y. Barkley, R.A.M.C. (S.R.); Lt.-Col. M. Boyle, R.A.M.C.; Temp. Capt. A. H. Coleman, R.A.M.C.; Temp. Capt. J. A. Delmege, R.A.M.C.; Temp. Capt. R. R. Elworthy, R.A.M.C.; Capt. (acting Maj.) W. B. Foley, R.A.M.C. (S.R.); Maj. W. R. Galwey, M.C., R.A.M.C.; Maj. (temp. Lt.-Col.) J. Gray, R.A.M.C. (T.F.); Lt.-Col. J. R. Hodgson, R.A.M.C.; Capt. H. E. McCall, R.A.M.C. (S.R.); Lt.-Col. P. Mitchell, R.A.M.C. (T.F.); Capt. (acting Maj.) J. Taylor, R.A.M.C. (T.F.); Lt.-Col. F. E. A. Webb, R.A.M.C. (T.F.).

M.B.E.—Lt. (temp. Capt., acting Maj.) R. A. Mansell, R.A.M.C.; Temp. Lt. J. Ramsbottom, R.A.M.C.

To be Brevet Lieutenant Colonel.—Maj. (temp. Lt.-Col.) J. A. Anderson, R.A.M.C.

To be Brevet Major.—Capt. (temp. Maj.) R. E. Burnley, M.C., R.A.M.C.; Capt. (acting Maj.) W. F. Christie, R.A.M.C.; Capt. (temp. Maj.) M. J. Williamson, M.C., R.A.M.C.

Military Cross.—Capt. R. D. Cameron, R.A.M.C. (S.R.); Capt. M. O. Cooper, R.A.M.C. (S.R.); Capt. G. B. Ege-ton, R.A.M.C. (S.R.); Temp. Capt. (acting Maj.) G. B. Holroyde, R.A.M.C.; Capt. L. J. Shell, R.A.M.C. (S.R.); Capt. H. W. Terrance, R.A.M.C. (S.R.); Capt. L. H. Wootton, R.A.M.C. (T.F.).

The following is the continuation of the list the first part of which was given in THE LANCET of Jan. 4th, p. 41:—

C.B.E.—Lt.-Col. J. T. Calvert, I.M.S.; Maj. J. H. Murray, I.M.S.; Lt.-Col. F. E. Swinton, I.M.S.; Lt.-Col. J. C. Lamont, I.M.S. (ret.).

C.B.E. (Military Division).—Surg. Capt. G. T. Broach, R.N.; Surg. Capt. V. G. Thorpe, R.N.; Maj. (Hon. Lt.-Col.) M. W. Flack; Acting Lt.-Col. F. F. Muecke.

O.B.E. (Military Division).—Surg. Cdr. R. F. Bates, R.N.; Surg. Cdr. R. Hardie, R.N.; Surg. Lt. A. B. Iles, R.N.; Surg. Lt.-Cdr. L. M. Morris, R.N.; Surg. Cdr. (acting Surg. Capt.) H. L. Penny, R.N.; Surg. Cdr. E. A. Shaw, R.N.; Lt.-Col. B. O. B. Carbery, Maj. B. O. Reilly, Canadian Forces; Maj. F. H. Stephens, A.M.S.; Capt. (temp. Maj.) H. O. Adams, R.A.M.C. (T.F.); Lt.-Col. W. J. P. Adye Curran, R.A.M.C.; Temp. Capt. (acting Maj.) J. A. Arkle, R.A.M.C.; Lt.-Col. (temp. Col.) H. P. W. Barrow, C.M.G., D.S.O., R.A.M.C.; Capt. (acting Maj.) C. B. Baxter, R.A.M.C. (T.F.); Temp. Lt. (acting Lt.-Col.) J. L. Birley, R.A.M.C.; Maj. H. d'A. Blumberg, T.D., R.A.M.C. (T.F.); Capt. (acting Maj.) H. Burrows, R.A.M.C. (T.F.); Temp. Capt. (acting Maj.) E. Charles, R.A.M.C.; Capt. A. D. Child, R.A.M.C. (S.R.); Capt. (acting Maj.) S. J. Clegg, R.A.M.C. (T.F.); Temp. Capt. N. A. Coward, R.A.M.C.; Capt. (acting Maj.) W. H. Davison, R.A.M.C. (T.F.); Temp. Maj. W. S. Dickie, R.A.M.C.; Temp. Maj. T. M. Frood, R.A.M.C.; Temp. Maj. (acting Lt.-Col.) G. D. Gray, R.A.M.C.; Capt. (acting Lt.-Col.) F. L. A. Greaves, R.A.M.C. (T.F.); Temp. Capt. A. H. Greg, R.A.M.C.; Capt. (acting Maj.) T. W. Hancock, R.A.M.C. (T.F.); Temp. Capt. (acting Maj.) J. H. Hebb, R.A.M.C.; Temp. Hon. Maj. T. Houston, R.A.M.C.; Capt. A. E. Jury, R.A.M.C. (T.F.); Temp. Capt. R. D. Laurie, R.A.M.C.; Temp. Capt. L. R. Lempiere, R.A.M.C.; Maj. (temp. Lt.-Col.) J. A. McCammon, M.C., R.A.M.C.; Temp. Capt. J. W. McLeod, R.A.M.C.; Temp. Capt. (acting Maj.) W. G. Mumford, R.A.M.C.; Capt. J. C. Newman, R.A.M.C. (T.F.); Capt. B. A. Odium, R.A.M.C.; Temp. Capt. R. I. P. Pelieu, R.A.M.C.; Capt. J. Ramsay, R.A.M.C. (T.F.); Temp. Capt. (acting Maj.) T. O. Ritchie, R.A.M.C.; Lt.-Col. (temp. Col.) A. B. Soltan, C.M.G.; R.A.M.C. (T.F.); Maj. (temp. Lt.-Col.) W. G. Sutcliffe, R.A.M.C. (T.F.); Maj. (acting Lt.-Col.) T. B. Unwin, R.A.M.C.; Capt. (acting Maj.) W. W. Wagstaffe, R.A.M.C. (S.R.); Temp. Capt. K. M. Walker, R.A.M.C.; Temp. Capt. (acting Maj.) H. B. Wilson, R.A.M.C.; Capt. (acting Lt.-Col.) T. B. Wolstenholme, R.A.M.C. (T.F.); Capt. (acting Lt.-Col.) F. Worthington, D.S.O., R.A.M.C.; Lt.-Col. P. G. Brown, Canadian A.M.C.; Maj. J. F. Burgess, Canadian A.M.C.; Maj. R. J. McEwan, Canadian A.M.C.; Lt.-Col. H. E. Munroe, Canadian A.M.C.; Maj. H. Orr, Canadian A.M.C.; Maj. D. M. Hmbelton, Australian A.M.C.; Maj. C. N. Finn, Australian A.M.C.; Maj. (temp. Lt.-Col.) A. F. Maclure, Australian A.M.C.; Lt.-Col. W. D. G. Upjohn, Australian A.M.C.

To be Major General.—Col. (temp. Maj.-Gen.) J. Thomson, C.B., A.M.S.

To be Brevet Colonel.—Lt.-Col. (temp. Col.) R. S. H. Fuhr, C.M.G., D.S.O., R.A.M.C.; Lt.-Col. (temp. Col.) A. G. Thompson, C.M.G., D.S.O., R.A.M.C.

To be Brevet Lieutenant Colonel.—Maj. (temp. Lt.-Col.) R. A. Bryden, D.S.O., R.A.M.C.; Maj. (temp. Lt.-Col.) P. J. Hanafin, D.S.O., R.A.M.C.; Maj. (temp. Lt.-Col.) H. S. Peeke, R. of O., late R.A.M.C.; Maj. (temp. Col.) D. Rorie, D.S.O., R.A.M.C. (T.F.); Maj. G. P. Sheehan, D.S.O., R.A.M.C.

To be Brevet Major.—Temp. Capt. S. P. Hodgkinson, R.A.M.C.; Capt. (acting Maj.) W. L. Webster, R.A.M.C.

P.S.O.—Surg. Lt.-Cdr. H. D. Drennan, R.N.; Capt. (temp. Lt.-Col.) J. Barkley, R.A.M.C. (T.F.); Capt. (acting Lt.-Col.) R. Burgess, M.C., R.A.M.C. (T.F.); Maj. (acting Lt.-Col.) A. Callan, R.A.M.C. (T.F.); Capt. (acting Lt.-Col.) L. D. B. Cogan, R.A.M.C. (T.F.); Maj. (acting Lt.-Col.) H. H. Cox, R.A.M.C. (T.F.); Capt. (acting Lt.-Col.) F. G. Dobson, R.A.M.C. (T.F.); Capt. (acting Maj.) T. I. Dun, M.C., R.A.M.C.; Capt. (temp. Lt.-Col.) O. W. Hames, R.A.M.C. (T.F.); Maj. (acting Lt.-Col.) G. T. Edmunds, R.A.M.C.; Maj. (acting Lt.-Col.) W. H. Forsyth, R.A.M.C.; Capt. (acting Lt.-Col.) C. J. A. Griffin, R.A.M.C. (S.R.); Capt. (acting Lt.-Col.) C. Helm, M.C., R.A.M.C.; Temp. Capt. (acting Maj.) A. E. Knight, M.C., R.A.M.C.; Capt. (acting Lt.-Col.) O. L. Lander, M.C., R.A.M.C. (T.F.); Maj. (acting Lt.-Col.) S. G. McAllum, R.A.M.C. (S.R.); Lt.-Col. (temp. Col.) F. McLennan, R.A.M.C.; Capt. (acting Lt.-Col.) J. Macmillan, M.C., R.A.M.C.; Capt. (acting Lt.-Col.) O. M. Page, R.A.M.C. (S.R.); Temp. Capt. (acting Maj.) M. P. Paton, M.C., R.A.M.C.; Maj. (acting Lt.-Col.) T. T. H. Robinson, R.A.M.C.; Maj. (acting Lt.-Col.) J. H. Stephen, R.A.M.C. (T.F.); Temp. Capt.

(acting Lt.-Col.) R. Svensson, M.C., R.A.M.C.; Capt. (acting Lt.-Col.) J. Young, R.A.M.C. (T.F.); Temp. Lt.-Col. C. W. Vipond, Canadian A.M.C.; Maj. (acting Lt.-Col.) J. H. Wood, Canadian A.M.C.; Lt.-Col. R. W. Chambers, Australian A.M.C.; Lt.-Col. W. B. L. H. Crowther, Australian A.M.C.; Maj. (temp. Lt.-Col.) E. F. Lind, Australian A.M.C.; Lt.-Col. G. W. Macartney, Australian A.M.C.; Maj. A. McKillop, Australian A.M.C.; Maj. C. Morlet, Australian A.M.C.; Maj. W. A. Morton, Australian A.M.C.; Maj. V. W. Savage, Australian A.M.C.; Maj. W. O. Sawers, Australian A.M.C.; Lt.-Col. G. Craig, N.Z.M.C.

Second Bar to the Military Cross.—Capt. H. K. Ward, M.C., R.A.M.C. (3.R.).

Bar to the Military Cross.—Temp. Capt. (acting Maj.) J. Biggam, M.C., R.A.M.C.; Capt. E. J. Bratley, M.C., R.A.M.C. (S.R.).

Military Cross.—Temp. Capt. R. J. Aherne, R.A.M.C.; Capt. (acting Maj.) W. R. Blore, R.A.M.C. (S.R.); Temp. Capt. A. Buchanan, R.A.M.C.; Capt. (acting Maj.) W. B. Cathcart, R.A.M.C. (S.R.); Capt. (acting Maj.) G. O. Chambers, R.A.M.C.; Temp. Capt. C. F. Drew, R.A.M.C.; Capt. B. McM. Dunlop, R.A.M.C. (T.F.); Temp. Capt. (acting Maj.) J. Gibson, R.A.M.C.; Capt. F. H. Guopy, R.A.M.C. (S.R.); Temp. Capt. (acting Maj.) E. L. M. Hackett, R.A.M.C.; Capt. G. L. Matthews, R.A.M.C.; Capt. (acting Maj.) C. Nicholson, R.A.M.C. (S.R.); Capt. (acting Maj.) A. P. O'Connor, R.A.M.C.; Temp. Capt. J. F. Powell, R.A.M.C.; Temp. Capt. C. R. Reckitt, R.A.M.C.; Capt. (acting Maj.) H. B. S. Richards, R.A.M.C. (T.F.); Capt. (acting Maj.) F. M. W. Rogers, R.A.M.C. (T.F.); Temp. Capt. S. P. Stoker, R.A.M.C.; Capt. (acting Lt.-Col.) D. H. Weir, R.A.M.C. (T.F.); Temp. Capt. (acting Maj.) B. Whitehead, R.A.M.C.; Temp. Capt. J. Wyllie, R.A.M.C.; Capt. N. J. MacKay, Australian A.M.C.; Capt. N. H. Dempster, N.Z.M.C.; Capt. A. D. S. Whyte, N.Z.M.C.

Katani-Hind Medal, 1st Class.—Mr. J. D. Price, Civil Surgeon, Nowgong, Assam.

MENTIONED IN DESPATCHES.

In a lengthy and most interesting despatch dealing with the brilliant victories of the British Army on the Western front which led up to the signing of the armistice on Nov. 11th last, Sir Douglas Haig pays the following tribute to the medical services:—

During the period under review the medical services, under the direction of Lieut.-General C. H. Birtchall, deserve special commendation for the initiative, energy, and success which have characterised all branches of their work. The rapid advance of the troops and the extended front on which operations were carried out during the final stages of the offensive created problems in connexion with the collection, evacuation, and treatment of wounded which had not been met with in the earlier phases of the war. These difficulties were met with the most admirable promptness and efficiency.

My thanks are due to the consulting surgeons and physicians for the invaluable assistance given by them in the application of new methods to the treatment of wounds and disease; to the R.A.M.C. officers and permanent staffs of the convalescent depôts for work which enabled many thousands of men to be restored to the fighting ranks; to the untiring and devoted work of the British Red Cross Society, the Order of St. John, and all members of the nursing service, whose unremitting kindness and constancy have done much to alleviate the sufferings of the sick and wounded; and, finally, for the very valuable services rendered by the base hospital units and by individual officers of the Medical Corps of the United States of America attached to the British Army.

The following medical officers of the Royal Air Force are mentioned in despatches for distinguished service in war areas:—

Surg. W. A. S. Duck, R.N. (Adriatic); Temp. Surg. A. L. Dykes, R.N. (Adriatic); Temp. Surg. R. S. Overton, R.N. (Mediterranean); Fleet Surg. C. E. C. Stanford, D.S.O., R.N. (Adriatic).

Also the following for distinguished and gallant services and devotion to duty in connexion with the operations of the British Force in Italy:—

Army Medical Service: Staff.

Lt.-Col. (temp. Col.) S. A. Archer; Lt.-Col. A. Chopping, C.M.G.; Capt. (acting Maj.) M. Copland, D.S.O., R.A.M.C. (T.F.); Col. J. V. Forrest, C.M.G.; Capt. (acting Maj.) T. D. Inch, M.C.; Temp. Capt. (acting Maj.) B. H. Lucas, M.C.; Maj.-Gen. F. R. Newland, O.B., C.M.G.; Lt.-Col. (temp. Col.) E. Pickard, C.M.G., T.D., R.A.M.C. (T.F.); Temp. Col. H. H. Tooth, C.B., C.M.G. (Lt.-Col., R.A.M.C. (T.F.)); Capt. (temp. Maj.) S. J. A. H. Walsh, D.S.O., R.A.M.C. (S.R.); Temp. Col. G. G. Watson, C.M.G.; Capt. (acting Maj.) J. D. Wells, R.A.M.C. (T.F.); Col. T. Du B. Whalley, C.M.G.

Royal Army Medical Corps.

Temp. Capt. C. J. Armstrong-Dash; Maj. (temp Lt.-Col.) J. G. Bell; D.S.O.; Maj. (acting Lt.-Col.) C. Bramhall; Temp. Capt. D. Fisher; Lt.-Col. C. H. Furnivall; Temp. Capt. H. B. T. Gamlen; Temp. Capt. D. G. Gardiner; Temp. Capt. (acting Maj.) J. Greene, M.C.; Temp. Capt. (acting Maj.) J. S. Hall; Lt.-Col. (acting Col.) H. A. L. Howell; Temp. Capt. W. Mackenzie; Temp. Capt. S. Marle; Temp. Capt. J. B. Matthews; Temp. Capt. (acting Maj.) A. A. Miller; Capt. (acting Maj.) J. A. Renshaw; Temp. Capt. (acting Maj.) R. H. Rollinson-Whitaker; Temp. Capt. H. S. Thomas; Capt. (acting Lt.-Col.) R. W. Vaughan, M.C.; Lt.-Col. J. W. West; Capt. (acting Col.) W. G. Wright, D.S.O.

Royal Army Medical Corps (S.R.).

Capt. J. E. Allan; Capt. (acting Maj.) T. O. Graham; Capt. A. Picken.

Royal Army Medical Corps (T.F.).

Capt. K. S. Beken; Capt. (acting Lt.-Col.) R. A. Broderick, M.C.; Capt. (acting Maj.) J. A. Davies; Capt. (acting Maj.) W. O. Hodges; Capt. G. Moore, M.C.; Capt. P. Moxey.

The following should be added to the list of those mentioned in despatches given in THE LANCET of Jan. 4th, page 41:—

Canadian Army Medical Staff.—Col. C. A. Peters, D.S.O.; Brig.-Gen. A. H. Ross, C.B., C.M.G.; Col. R. M. Simpson, D.S.O.; Col. R. P. Wright, D.S.O.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments are notified:—Surg. Com. W. H. Daw to *Donegal*; Surg. Lieut.-Com. R. C. Holton to *Bristol*; Surg. Lieut. I. S. Gabe to Royal Marine Division, Chatham.

ROYAL NAVAL VOLUNTEER RESERVE.

Temp. Surg. Lieut. H. G. Davies, R.N.V.R., who has been invalided on account of ill-health contracted in the service, to retain his rank.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonels to be acting Colonels while employed as Assistant Directors of Medical Services of a Division: A. E. Hamerton, H. C. R. Hime, (Brevet Col.) G. J. A. Ormsby.

The undermentioned relinquish the acting rank of Lieutenant-Colonel on re-posting: Major W. J. Weston; Capt. W. Tyrrell.

To be acting Lieutenant-Colonels whilst in command of a Medical Unit: Capt. G. F. Rudkin, Capt. (acting Major) M. White, Capt. H. H. Leeson, Capt. (acting Major) M. J. Williamson, Major W. E. C. Lunn, Capt. (acting Major) J. B. A. Wigmore, Capt. (acting Major) G. D'R. Carr, M.C.

Lieut.-Col. F. S. Le Queane, V.C., is placed on retired pay.

Temporary Colonels relinquishing their temporary commissions on re-posting: R. B. Kelly (Captain, R.A.M.C., T.F.), H. A. Ballance (Major, temp. Lieut.-Col., R.A.M.C., T.F.).

Lieut.-Col. J. E. Brogden is placed temporarily on the Half pay List. To be acting Majors: Capt. B. Varvill, K. P. Mackenzie, W. E. Tyndall; Temp. Capt. A. W. P. Todd, W. K. A. Richards, D. J. Stokes, J. H. Hood, J. Rodger, D. S. Graham, D. E. Williams, O. N. Oost, A. L. Saunders, R. Felton, G. S. Brown, and D. M. Ross, and W. H. Scott while commanding troops on a Hospital Ship.

Temp. Capt. relinquishing the acting rank of Major on re-posting: R. V. Doloy, W. D. Cruickshank, W. G. Johnston, W. K. A. Richards, K. Wilson.

J. E. Briscoe to be Captain.

Temp. Hon. Capt. H. O. Stansfield to be acting Major whilst specially employed.

Temporary Lieutenants to be temporary Captains: F. W. Daniels, S. B. Turner, D. Holroyde.

Temp. Hon. Lieut. A. C. Delacroix to be temporary honorary Captain.

Officers relinquishing their commissions:—Temp. Majors: A. H. Bindloss, J. B. Howell, Temp. Hon. Major W. C. G. Ashdowns, Temp. Capt. G. Denholm, A. G. H. Lovell, G. N. Limer, T. Claperton, E. A. Miller, R. J. McPeeters, C. J. A. N. Mercier, C. M. Young, M. J. Ryan, W. G. B. Gunn, (Acting Major) B. H. Barton, F. J. Child, E. C. Bourdas, A. B. Aitken, C. E. Lakin, C. S. Kingston, J. A. Gray (Home Hospital Reserve), A. Westerman, A. R. Jordan, A. C. Hallowes, J. B. McMorland, J. E. English, H. Dyer, A. Dingwall, T. E. Ferguson, S. Vosper, R. J. Helsby, (Acting Major) E. L. M. Hackett, W. Rolland, W. W. Livingston, J. A. Davidson, H. M. Raven, E. C. Roberts, H. P. Newsholme, A. D. Hunt, (Acting Major) W. Anderson, G. Hardwicke, M. J. Liddell, J. L. Cochrane, J. R. Tibbles, G. D. E. Tullis, J. B. Ferguson, (Acting Major) R. Warren, A. Currie, W. A. Young, M. J. Horgan, E. E. M. Price, W. R. Bayne, H. S. Gabb, R. F. Moore, A. F. W. Denning, H. L. Tide, J. H. Porter (Acting Major) C. H. S. Webb, K. W. D. MacRae, N. Morris, H. S. A. Hogg, N. A. Coward, O. W. Jones, R. D. Smedley, F. P. Fisher, G. Allison, G. B. Wilkinson, R. M. Liddell, (Acting Major) W. Rankin, (Acting Major) R. H. Paramore, T. L. Wormald, B. H. Walker, (Acting Major) J. L. Gordon, S. Carter, A. J. V. McDonnell, C. R. Willis, A. Gillespie, W. H. Pallett, R. M. Soames, J. O. Skewington, T. S. Sharpley. To retain the rank of Captain: E. B. Struthers. On account of ill-health contracted on active service and to retain the rank of Captain: A. C. B. Biggs, A. H. Sinclair, D. W. Jones, (Acting Major) W. A. Rogers. On account of ill-health contracted on active service. C. Dundee, D. C. Alexander, F. L. Brewer, H. L. Marlyn. On account of ill-health and to retain the rank of Captain: A. W. F. Edmunds, J. McCartney. On account of ill-health: Temp. Hon. Capt. R. M. Blake (on ceasing to serve with the British Red Cross Society in France), J. M. Smith on account of ill-health and is granted the rank of Lieutenant. Temp. Lieuts.: C. J. E. Edmunds, F. P. R. James, A. Linn, G. S. Ward, D. G. Gellatly, F. G. F. Browns, D. Davies, D. Holroyde, H. Caird, W. J. N. Todd, R. Hamer, A. L. Black, W. L. Hogan, F. W. Hobbs; Temp. Hon. Lieut. J. P. Griffin (on ceasing to serve with the British Red Cross Hospital, Neuilly).

Canadian Army Medical Corps.

Temporary Lieutenants to be temporary Captains: J. W. Harper, G. Leith, A. E. Kennedy, D. MacDougall, P. H. McNulty, G. A. Minorgan, W. E. Munro, J. B. Pritchard, E. Wershof, A. S. McCann.

Canadian Army Dental Corps.

Temp. Lieut. C. W. Smith, from Canadian Machine Gun Corps, to be temporary Lieutenant.

SPECIAL RESERVE OF OFFICERS.

Capt. F. G. Foster and S. J. V. Furlong to be acting Majors.

Lieut. J. F. Cunningham relinquishes his commission on account of ill-health.

Second Lieut. E. P. Whiteman to be Lieutenant.

TERRITORIAL FORCE.

General List.—Capt. (Brevet Major) (acting Lieut.-Col.) R. O. Dun, relinquishes his acting rank on ceasing to be specially employed.

Capt. (acting Majors) J. Walker, F. W. O. Brown, and F. H. Lacey relinquish their acting rank on ceasing to be specially employed.

Major (acting Lieut.-Col.) D. G. Campbell relinquishes his acting rank on ceasing to be specially employed.

Captains to be acting Majors whilst specially employed: J. W. Thomson, J. W. Craven, J. O. Newman, R. M. Wilson.

Capt. J. W. Keay to be Major.

1st Eastern General Hospital: Major (acting Lieut.-Col.) H. A. Ballance relinquishes his acting rank and is restored to the establishment.

1st London Sanitary Company: Lieut. S. W. Wingfield to be Captain.

1st London General Hospital: Capt. P. Hamill is restored to the establishment.

TERRITORIAL FORCE RESERVE.

Lieut.-Col. W. E. Foggie, from 3rd Highland Field Ambulance, to be Lieutenant-Colonel.

Majors F. N. Grinling, W. T. Rowe, D. G. Campbell, A. C. Turner, B. R. Dyer, J. R. Garrod, B. G. Ewing, G. F. R. Smith, A. A. Gunn, from Attached to Units other than Medical Units, to be Majors.

Major (acting Lieut.-Col.) P. G. Williamson, from Attached to Units other than Medical Units, to be Major.

A. A. W. Merrick, from 3rd West Lancs. Field Ambulance to be Major.

Capt. J. R. Chalmers and C. W. Greene from 1st Home Counties Field Ambulance, to be Captains.

Capt. (acting Major) A. R. Muir, from Lowland Mounted Brigade Field Ambulance, to be Captain.

Capt. N. T. K. Jordan, from South Wales Mounted Brigade Field Ambulance, to be Captain.

Capt. (acting Major) J. G. Cooke, from Attached to Units other than Medical Units, to be Captain.

Capt. (acting Major) H. F. W. Boeddicker, from 1st South Midland Field Ambulance, to be Captain.

Capt. P. H. Lacey, from Welsh Border Mounted Brigade Field Ambulance, to be Captain.

Capt. L. A. Mackenzie, from 1st West Riding Field Ambulance, to be Captain.

Capt. A. A. Pratt, from 4th Northern General Hospital, to be Captain.

Capt. H. Stonehouse, from the 2nd Northern Field Ambulance, to be Captain.

Capt. W. J. Wilkinson, from 2nd East Anglian Field Ambulance, to be Captain.

Capt. W. Bailey-Thomson, from Notts and Derby Mounted Brigade Field Ambulance, to be Captain.

Capt. G. H. Kirby, from South Midland Casualty Clearing Station, to be Captain.

Capt. J. H. Paul, from Yorks Mounted Brigade Field Ambulance, to be Captain.

Capt. W. L. Hibbert, from Home Counties Casualty Clearing Station, to be Captain.

Capt. D. Macnair, from 2nd Wessex Field Ambulance, to be Captain.

Capt. H. N. Crowe, from 2nd South Midland Field Ambulance, to be Captain.

Capt. (acting Major) H. C. Adams, from 2nd Wessex Field Ambulance, to be Captain.

ROYAL AIR FORCE.

Medical Branch.—Major J. L. Byles to be acting Lieutenant-Colonel while employed as Lieutenant-Colonel. The following are granted temporary commissions: As Lieutenant-Colonel: Surg.-Commander C. R. C. Stanford. As Majors: Acting Majors: R.A.M.C., W. W. Shorten, T. J. Kelly, B. H. Robinson; Staff-Surge, R.N., F. H. Stephens, A. V. J. Richardson. As Captains (acting Majors while specially employed): Acting Majors, R.A.M.C., M. N. Perrin, J. H. Porter. As Captains: Surg. Lieut., R.N., W. A. S. Duck, D. S. Stevenson, P. B. Gillespie, D. Ross, R. W. Meller, A. L. Dykes, L. S. Goss, R. B. Adams, J. H. M. Sanderson, B. McLean; Surg. Lieut., R.N.V.R., C. F. A. Hereford, T. B. Dixon, D. A. Macpherson; Capt., R.A.M.C., D'Arcy Power, J. H. Owen, A. Sutcliffe, J. M. Wyatt, F. A. Hampton, N. C. Graham, A. G. H. Smart, L. W. Shelley, C. P. Seals, E. W. Craig, W. J. McKeand, A. G. H. Moore, W. S. T. Connell, J. Freeman, G. Cranston, W. Waugh, O. F. Graves, D. H. Fraser, W. H. Cam, J. W. Kay, A. D. Kennedy, J. B. Laessle, C. H. Thompson, J. E. Dunbar, V. T. Ellwood, J. H. Cooke, P. H. Young, J. Chamberé, T. N. Wiltshire, A. Litch, C. K. Atlee, O. W. W. James, W. B. Dove.

G. D. M. Beaton (temporary Lieutenant, R.A.M.C.) is granted a temporary commission as Lieutenant.

Dental Branch.—As Captains: J. Barratt, G. Dawson, L. S. Woodliffe.

THE LANCET, VOL. II., 1918: THE INDEX.

THE Index and Title-page to the volume of THE LANCET which was completed with the issue of Dec. 28th, 1918, is in preparation. Owing to the continued shortage in the paper-supply, the Index will not be issued with all copies of THE LANCET, as was the custom prior to the War. Subscribers who bind up their numbers are requested to send a post-card (which is more convenient for filing purposes than a letter) to the Manager, THE LANCET Office, 423, Strand, London, W.C. 2, when a copy of the Index and Title-page will be supplied free of charge.

Medical News.

UNIVERSITY OF ABERDEEN.—The following degrees were conferred recently:—

M.B. and Ch.B.—Patrick Stephen Gerrard Cameron, Marjory Johnston Dufton, Anne Simpson, and John Geddes Smith (second-class honours).

ROYAL SOCIETY OF MEDICINE.—The Section for the Study of Disease in Children will hold a discussion upon the Etiology, Prevention, and Non-operative Treatment of "Adenoids" at 1, Wimpole-street, on Friday, Jan. 24th, at 5 P.M. The discussion will be opened by Dr. Harry Campbell and Dr. Edmund Cantley.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—An ordinary meeting of this society will be held to-day (Friday, Jan. 10th) in the society's rooms, West London Hospital, at 8.30 P.M., when a paper will be read by Major W. McAdam Eccles, entitled "Stumps and their After-treatment."

MEDICAL MAGISTRATE.—Dr. G. W. Eustace, ex-Mayor of Arundel, has been placed on the commission of the peace for Sussex. He was awarded the Military Cross for gallantry at Ypres in September, 1917, being then attached to the Queen Victoria Rifles. Dr. Eustace also served in the South African War, receiving the medal and three clasps.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—A meeting of the General Council of King Edward's Hospital Fund for London was held on Jan. 6th at the offices of the Fund, 7, Walbrook, E.C., the Right Hon. James W. Lowther, M.P. (Speaker of the House of Commons), in the chair, when the order of appointment to the council, committees, and executive was read, and the resolutions providing for the work of the Fund for 1919, approved by the governors on Dec. 17th last, were formally adopted.

KING GEORGE'S FUND FOR SAILORS.—At a meeting of the general council of this fund, which was held at Trinity House on Dec. 20th last, it was announced that £50,000 had been allocated to the Marine Benevolent Institutions. The fund has for its object the amelioration of distress among seamen and their dependents, and letters were read at the meeting from the King and other members of the Royal Family expressing their gratification at the success of the fund and their appreciation of the generous response on the part of the public, both in this country and in the dominions and colonies. His Majesty expressed the wish that next year the donations might reach a total of £1,000,000.

UNIVERSITY OF EDINBURGH.—The following medical items from the annual report for 1917-18 are of interest:—

During the academic year 1917-18 the total number of matriculated students was 2091, of whom 1339 were men and 752 were women. Of these there were enrolled in the Faculty of Medicine 1147 (823 men and 324 women—an increase of 84 up in the number of women for the previous session). Of the students of medicine, 588, or over 51 per cent., belonged to Scotland; 199, or over 17 per cent., were from England and Wales; 26 from Ireland; 299, or 26 per cent., from British Dominions, Colonies, and Dependencies of whom 76 came from India and 25 from foreign countries. The following medical degrees were conferred: Bachelors of Medicine and Bachelor of Surgery 106, Doctor of Medicine 15. The total annual value of the University fellowships, scholarships, bursaries, and prizes now amounts to about £21,485, of which £25610 belongs to the Faculty of Medicine. The coming of peace has already brought back many former students, and others have entered the commencement of whose course had been delayed by military service. When the spring term opens there will be a further large augmentation of numbers in all departments of study. The University authorities are addressing themselves to the various problems which lie ahead, and it is hoped that, aided by some reasonable relaxation of preliminary requirements and by the provision of courses of instruction adapted to the special needs of the time, the case of the returning student will be adequately and even generously dealt

with. The University of Edinburgh, in common with the other universities of Great Britain, has drawn up a statement of its most pressing financial needs, and it is anticipated that the Government will supplement their existing grants to some extent. Two vacancies have occurred during the year in the ranks of the professoriate, one by resignation, the other owing to death. Sir Thomas Fraser resigned, as from the end of September, the chair of materia medica, which he had held for 41 years, adding lustre to the University during this long period, not less by the importance of his scientific investigations than by his success as a teacher. He has been succeeded by Mr. A. R. Cushny, who was formerly professor of materia medica and pharmacology in the University of London. The deaths of two University lecturers are recorded—viz. Dr. W. G. Smith, who was appointed to the George Combe Lectureship in Psychology on its institution in 1906, and who, in spite of indifferent health, discharged the duties devolving upon him with exceptional competence and devotion; and Mr. Denis Cotterill, one of the lecturers in clinical surgery, who for several years rendered services of the highest value in connexion with No. 11 Hospital, Rouen. Sir William Watson Cheyne, Bart., K.C.M.G., has been elected as one of the three Parliamentary representatives for the universities of Scotland. Among the benefactions is a bequest by the late Dr. Grace R. Cadell, to the University, jointly with the Edinburgh Hospital for Women and Children and Hospice, of the residue of her estate; the moiety falling to the University being "to help in the medical education of women in that University."

Lord Ashton, of Ryelands, Lancaster, has sent to the Preston Royal Infirmary a cheque for £2000 to free the institution from debt.

THE subscriptions to the French War Medical Assistance Fund have reached a total of more than a million francs. This fund also makes grants to the families of medical men. Its address is 5 rue de Surène, Paris.

UNIVERSITY OF LONDON.—Dr. John W. H. Eyre (Guy's Hospital Medical School) has been appointed professor of bacteriology, and Dr. Arthur E. Boycott, F.R.S., has been reappointed director, and Dr. C. Bolton, F.R.S., acting director, of the Graham Legacy Laboratory, during Dr. Boycott's absence on military duty.—In cooperation with the London County Council the University has arranged a series of five lectures for teachers on "Surgery, Ancient and Modern, with special reference to Lister and Pasteur," which will be delivered by Sir Rickman J. Godlee at University College on Wednesdays, at 5.30 p.m., beginning on Jan. 22nd. Sir Cooper Perry will preside at the opening lecture.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W. 1.
Tuesday, Jan. 14th.

GENERAL MEETING OF FELLOWS, at 5 p.m.

Discussion:

On "Conditions under which Pensioners of the Army, Navy, and Royal Air Force are Admitted into and Treated in Civil Hospitals," to be opened by Mr. H. J. Waring. Any Fellow wishing to take part in the Discussion should send his name to the Secretary as soon as possible.

MEETINGS OF SECTIONS.

Tuesday, Jan. 14th.

PSYCHIATRY (Hon. Secretaries—Bernard Hart, G. F. Barham): at 3.30 p.m.

CLINICAL MEETING at the Ewell War Hospital by courtesy of Lt.-Col. M. A. Collins, R.A.M.C., D.D.M.S. Eastern Command, and of the Committee, L.C.C.

Train leaves Waterloo at 2.37 p.m., arriving Ewell 3.10 and Epsom 3.15. Return train leaves Ewell at 5.59 p.m. for Waterloo.

Wednesday, Jan. 15th.

HISTORY OF MEDICINE (Hon. Secretaries—Charles Singer, Arnold Chaplin): at 5 p.m.

Papers:

Sir William Osler: A Bodley MS. of Lectures of Andrea Cesalpino, 1590.

Dr. Cumston: A Contribution to the History of the Surgical Treatment of Aneurysm, from notes of Dr. Charles Maunoir of Geneva, made in 1822.

Thursday, Jan. 16th.

DERMATOLOGY (Hon. Secretary—S. B. Dore): at 4.30 p.m.

Cases will be shown.

Friday, Jan. 17th.

OTOLOGY (Hon. Secretaries—J. F. O'Malley, H. Buckland Jones): at 5 p.m.

Paper:

Mr. Hugh E. Jones (President of the Section): Deafness associated with the Stigmata of Degeneration.

ELECTRO-THERAPEUTICS (Hon. Secretaries—Robert Knox, Walter J. Turrell): at 8.30 p.m.

Adjourned Discussions on the following Papers:—

A Note on the Construction of the Diathermy Machine (with demonstration): by O. M. Dowse, B.Sc., and C. E. Iredell, M.D. Diathermy in Gynaecological Cases: by G. Bellingham Smith, F.R.C.S., C. E. Iredell, M.D., and A. E. Maraden, Surgeon, R.N. Personal Experiences of Burning due to Secondary Radiation: by James Metcalfe, M.D. Diathermy and Fulguration in Malignant Disease: by Philip Turner, F.R.C.S., Lt.-Col., R.A.M.C., and C. E. Iredell, M.D.

Papers:

Diathermy in Diseases of the Eye: by O. Meadows-Ryley, Surgeon, R.N., and C. E. Iredell, M.D. The Diathermy of the Abdomen: by C. E. Iredell, M.D., with a Note by W. H. Barber, M.D., Capata, R.A.M.C.

Dr. S. Gilbert Scott will show lantern slides of interesting cases.

CLINICAL

OBSTETRICS AND GYNAECOLOGY

SURGERY: Members of these Sections are specially invited to attend the Meeting of the Section of Electro-Therapeutics.

The Royal Society of Medicine keeps open house for R.A.M.C. men and M.O.'s of the Dominions and Allies. The principal hospitals in the metropolis admit medical officers to their operations, lectures &c. Particulars on application to the Secretary at 1, Wimpole-street, London, W. 1.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY, Jan. 17th.—5.30 p.m. Paper:—Lt.-Col. S. P. James, I.M.S. (ret'd.): Malaria in England.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

Clinics each week-day at 2 p.m., Wednesday, Friday and Saturday also at 10 a.m.

(Details of Post-Graduate Course were given in issue of Nov. 30th, 1918.)

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY, Jan. 14th.—5 p.m., Dr. W. K. Sibley: Ionisation.

WEDNESDAY.—5 p.m., Dr. W. Grimsby: Skin Diseases in the Army.

ROYAL INSTITUTE OF PUBLIC HEALTH, in the Lecture Hall of the Institute, 37, Russell-square, W.C.

Course of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—

WEDNESDAY, Jan. 15th.—4 p.m., Prof. W. A. Bone: Coal and National Health.

THE King has conferred the Order of Merit on Lieutenant-Colonel R. R. Sleman, R.A.M.C.

CLASSES in the various faculties were resumed in the University of Lille on Jan. 3rd. The Faculty of Medicine in Brussels reopens its doors in the course of the month.

Appointments.

ALFORD, H. J., M.D. Lond., has been appointed Consulting Medical Officer of Health and School Medical Officer to the Taunton Town Council.
BULLOUGH, WILLIAM A., M.B., Ch.B., County Medical Officer of Health for Essex.
WILLIAMS, A. H., M.D. Edin., Commissioner of Medical Services for the North-West Region, which includes the whole of Lancashire and Cheshire.

Vacancies.

For further information refer to the advertisement columns.

Aylesbury, Bucks County Asylum.—Asst. M.O. £350.
Birmingham, St. Charles Hospital.—Res. M.O. £150.
Bath Royal United Hospital.—H.P. and H.S.
Bedford County Hospital.—Res. Clin. Asst. £2 2s. per week.
Bolingbroke Hospital, Wandsworth Comm., S.W.—Res. M.O. £200.
Bradford Royal Infirmary.—H.S.
Bristol General Hospital.—Sen. H.S. £300.
Chichester, Royal West Sussex Hospital.—H.S. £160.
Dorchester, Dorset County Asylum.—S. cond. Asst. M.O. £300.
Dudley County Borough.—M.O. H. and School M.O. £s. £175.
East Ham County Borough.—Female Asst. M.O. £400.
East London Hospital for Children and Dispensary for Women, Shadwell E.—Asst. Res. M.O. £125. Also Casualty Officer. £120.
Edinburgh, Venereal Diseases Scheme.—Female Asst. M.O. £400.
Exeter City Mental Hospital, Digby, near Exeter.—Asst. M.O. £300.
Gloucester County Asylum, Bridgford.—Temp. Asst. M.O. £8 6s. per wk.
Glasgow Central Hospital, Holloway-road, N.—H.S. £150.
Guildford, Royal Surrey County Hospital.—H.S. £250.
Hellingly, East Sussex County Asylum.—Temp. Asst. M.O. 7 gs. per wk.
Hull City Education Committee.—Asst. Female School M.O. £400.
Hospital for Consumption and Diseases of the Chest, Brompton.—H.P. £300.
Manchester, Ancoats Hospital, Mill-street.—Hon. P.
Margate, Royal Sea-Bathing Hospital for Surgical Tuberculosis.—S. £200.
Monmouthshire County Council.—Female Asst. M.O. £400.
North Riding Asylum.—Locum Tenens M.O. 1 gs. per week.
Northampton County Borough.—Temp. Tuberc. Officer. £400.
Norwich, Norfolk and Norwich Hospital.—H.P. £250. Hon. P.
Painey Hospital, Lower Common, S.W.—Res. M.O. £150.
Queen's Hospital for Children, Hackney-road, E.—Temp. Asst. P's. £25.
Reading, Royal Berkshire Hospital.—Hon. P.
Rushdale Infirmary and Dispensary.—Jun. H.S. £100.
Rochester, St. Bartholomew's Hospital.—Clin. Asst. £150.
Rotherham Hospital.—Sen. H.S. £250.
Royal Free Hospital, Gray's Inn-road, W.C.—H.P. £50. Casualty H.S. £100.
Surrey Education Committee.—School Dentist. £300.
Swansea Hospital.—Res. Senior Student. £150.
Swindon Borough.—Asst. M.O. £50.
Victoria Hospital for Children, Tite-street, Chelsea, S.W.—H.P. and H.S. £200.
Westmorland Sanatorium, Meathop, Grange-over-Sands.—Asst. M.O. £50.
Whitehaven and West Cumberland Infirmary.—Res. H.S. £150 to £185.
The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Knutsford, Folkestone, Blackburn, Preston, and Harrogate.

Births, Marriages, and Deaths.

BIRTHS.

GRATTAN-GUINNESS.—On Dec. 30th, 1918, at Madeley, Shropshire, the wife of Dr. A. P. Grattan-Guinness of a daughter.
MOYSE.—On Jan. 2nd, at Church Hill House, Stalbridge, Dorset, the wife of H. H. Moyse, M.R.C.S., L.R.C.P., of a daughter.

MARRIAGES.

OWEN-WEBB.—On Jan. 1st, at Haslemere, Captain Dennis Crile, B.A.M.O., Harvard Unit, to Mary Dorothea, elder daughter of Major and Mrs. H. N. Webb, of Walsby, Haslemere.
HALL-ROULEDGE.—On Jan. 1st, at St. John's, Holland road, W., Robin Hall, M.B., B.Ch., B.A., Captain, Royal Air Force, elder son of Dr. and Mrs. Robert Hall, of Belfast, to Geraldine Blais, only daughter of Mr. and Mrs. Gerald Edmund Routledge, of Kensington, W.
SWINER GRANT.—On Jan. 1st, at St. James's, Preston, Louis Bruce Swinger, Captain, R.A.F. Medical Service, to Maud, third daughter of Mr. and Mrs. John Grant, of Preston, Lancashire.

DEATHS.

ELLS.—On Jan. 2nd, in London, William Ashton Ellis, M.R.C.S., L.R.C.P.
HARRIS.—On Dec. 31st, 1918, at Leamington, in a Nursing Home, Stuart Harris, M.B., L.R.C.S. Edin., aged 80.
MACKINNON.—On Dec. 30th, 1918, at Alexandria, of pneumonia, Frank I. Mackinnon, M.B., C.M., M.R.C.S. (of Damascus), Captain, R.A.M.C. (temporary), aged 63.
N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

COLONIAL HEALTH REPORTS.

Ceylon.—It appears from the Blue-book for 1917 that the population at the end of that year was estimated at 4,632,400. This showed a net increase of nearly 85,000 over that of the previous year, and was made up of an excess of about 70,590 births over deaths, of 15,180 arrivals over departures of Indian coolies, and of a reduction of nearly 270 persons of the European population who left for war service. The following are details of the population:—

| Nationality. | No. | Percentage of total population. | Nationality. | No. | Percentage of total population. |
|---------------|-----------|---------------------------------|---------------|--------|---------------------------------|
| Sinhalese ... | 2,861,100 | 63.7 | Malays ... | 14,000 | 0.3 |
| Tamils ... | 1,338,100 | 28.9 | Europeans ... | 7,200 | 0.2 |
| Moors ... | 276,450 | 5.9 | Others ... | 18,000 | 0.4 |
| Bughaes ... | 28,780 | 0.6 | | | |

To every 100 males of the population there are 89 females. The birth-rate was 40.1 per 1000 of the population, and was 2.6 higher than the average of the preceding decennium. It was the second highest on record, being 0.9 below that of 1908, which was the highest. The proportion of male to female births was 104 to 100. The death-rate was 24.7 per 1000, the lowest recorded during the last 10 years. The proportion of male to female deaths was, like the proportion of births, 104 to 100. Of the total deaths registered during the year 28.2 per cent. were those of infants under 1 year of age, corresponding to a mortality-rate of 174 per 1000 births registered. This rate is 20 per 1000 below the average for the preceding decennium, and 10 per 1000 below that for 1916. The proportion of deaths in the general community from certain principal causes to a million of the estimated population was as follows: Infantile convulsions, 2814; diarrhoea, 2217; pneumonia, 1090; phthisis, 821; dysentery, 666; ankylostomiasis, 575; puerperal septicæmia, 401; premature birth and congenital defects, 349; malaria and malarial cachexia, 278; bronchitis, 189; cancer, 92; and enteric fever, 91. Plague, which broke out in Ceylon for the first time in 1914, is still continuing its scourge, having claimed as its victims in the year under review 211 persons, against 286 in 1916. Accidental drowning accounted for 95 deaths per million population, falls from trees for 83, and snake-bite for 46. 240 deaths (including 2 Europeans) resulted from suicide, homicide accounted for 183, and 38 were due to judicial hanging. That the reduction in the number of plague cases during 1917 was in no way due to the virulence of the infection having abated is indicated by the steady rise in the case mortality, which was 92.2 per cent. in 1914, 92.8 in 1915, 93.8 in 1916, and 94.7 in 1917. As hitherto, the largest number of cases occurred amongst young adults, males being attacked more frequently than females. The disease was, as usual, almost entirely confined to the occupants of insanitary tenements. Out of a total of 23,382 rats examined bacteriologically, only 70, or 0.3 per cent., were infected, by far the largest number being found in an area which is the chief centre of the petty trade in grain. It is of special interest to record that three out of six cats examined were found to be heavily infected. The same preventive measures as hitherto were carried out, reliance being placed chiefly upon isolation of patients in hospital, segregation of contacts, evacuation and closure of insanitary tenements in infected localities pending the carrying out of structural improvements by the owners, pestering of infected and adjacent houses, sulphur fumigation of rat tunnels, capture and poisoning of rats. The campaign against ankylostomiasis, which is extremely prevalent in practically every part of the island, was carried on throughout the year by officers of the International Health Commission, whose work is much appreciated, in conjunction with the medical department. There are 84 Government hospitals and 441 Government outdoor dispensaries. The owners of private estates have provided 58 estate hospitals and 401 dispensaries. Three new hospitals were opened during the year and several others are under construction. The lunatic asylum contained on Dec. 31st, 1917, 1030 inmates. The leper asylum, situated six miles from Colombo, contained 429 patients at the end of the year. A smaller establishment for lepers exists at Kalmunai, in the Eastern Province, with accommodation for 30, and a leper colony at Mantivu, a small island on the lagoon in the neighbourhood of Batticaloa, is being erected. A Home for Incurables (containing 80 beds) is administered by a committee of Government officials and representatives of the public. The general rebuilding scheme in contemplation for the improvement of the Medical College was deferred owing to the war. The full course of training for medical

students is five years. A diploma in medicine, surgery, and midwifery (which can be registered in the United Kingdom), is granted to successful medical students. A two years' course of training is provided for apothecaries, who, on becoming qualified, are employed by Government. The attendances during 1916 and 1917 totalled—medical, 620; apothecary, 253: the passes were—medical, 30; apothecary, 30. In Colombo there are a bacteriological institute, a general hospital, an ophthalmic hospital, a lying-in home, a hospital for women and children, and one for infectious diseases. There is an establishment for the manufacture of calf lymph, and at Kandy and Galle there are special dispensaries for the treatment of eye diseases. An antituberculosis institute in Colombo was opened during the year, fitted with an up-to-date X ray apparatus. A start was also made in connexion with the provision of a Pasteur Institute in Colombo.

ELECTROLYTIC DISINFECTANT IN INFLUENZA.

IN view of the Memorandum on Epidemic Influenza which has been issued by the Royal College of Physicians of London (THE LANCET, Nov. 16th, 1918), in which, as a preventive, is recommended gargling the throat with 20 drops of solution of chlorinated soda in a tumbler of warm water and sniffing up the nose a solution of common salt, Mr. F. W. Alexander, medical officer of health of Poplar, sends us an account of the method adopted in that borough for dealing with the outbreak. The drawbacks to using chlorinated soda on a large scale are that it is difficult to make and has to be freshly prepared. The electrolytic fluid as made in Poplar contains common salt and hypochlorite of magnesium (a solution of chlorinated magnesium), it is alkaline and stable, and if it is necessary to give it a tint permanganate of potash may be used for the purpose, as it retains its colour when added to the solution. During the first three weeks of November 5370 gallons were distributed free in the borough, the cost, including that of electricity and materials, being 1d. per gallon (or about £12 per 5370 gallons). This fluid has been available free in Poplar for the last 12 years, and as soon as influenza broke out in the borough handbills were distributed and the district posted with bills instructing the inhabitants to rinse the mouth, gargle the throat, and douche the inside of the nose with the council's electrolytic disinfectant, which could be procured free at one of the council's seven distributing depôts. Mr. Alexander points out the advantages of installing plants for making the fluid, especially on ships and at seaside towns, where the electrolyte is always at hand and always ready. It could be used immediately in outbreaks of diphtheria and cerebro-spinal fever.

OIL OF CHENOPODIUM FOR ANKYLOSTOMIASIS.

IN the Colonial Health Report from Ceylon, which we notice on page 89, the extreme prevalence of ankylostomiasis in that island is noted. A note in the current number of the *Colonial Journal* quotes a report from the Fiji Islands stating that the employment of the oil of chenopodium, or American wormseed oil, is constantly increasing there. The reasons given for the use of this drug are that it is less toxic, more efficient, less costly, and has a greater effect upon the ascarides associated with hookworms than thymol. Failure to obtain good results with the oil of chenopodium is claimed to be due to small dosage, the correct amount being as follows: Over 60 years of age, 20 m or 40 drops; 21 to 60 years, 30 m or 60 drops; 11 to 20 years, 20 m or 40 drops; under 10 years, 3 drops for each year of age; pregnant women, 18 drops. The doses are divided into two equal parts, one to be given at 7 A.M. and the other at 9 A.M., these being preceded by a dose of well-diluted magnesium sulphate on the afternoon of the day before treatment with the oil is begun. Two hours after the last dose of oil a second dose of the salts solution is given. A report based on the first 1000 cures occurring in Fiji states that of those receiving two treatments 70 per cent. or more are cured. In a few selected parts where the people were obedient to advice in regard to diet the cures after two treatments reached 85 per cent. Of the 1000 cures obtained in the first three months of active work, 801 occurred after two treatments, 184 after four treatments, and the remaining 15 cures after five treatments. No untoward results have been reported from the use of the drug.

HEALTH TEACHING.

THE importance of right training in hygiene, especially at school age when the future citizen is under control for training, was admirably discussed in his first Milroy lecture last year by Professor H. R. Kenwood and reported in THE LANCET of May 11th. In this connexion the health and temperance syllabus drawn up for the Natal Education Department by its medical officer, Dr. A. B. MacArthur Thomson, for the instruction of hygiene in elementary schools, is of interest, for it is a genuine attempt to introduce

practical instruction in place of a pseudo-scientific method of teaching. The syllabus is graded to suit the various Standards I. to VI., and includes, in addition to the usual subjects of food, air, and cleanliness, instruction in first-aid. In Standard V. reproduction is discussed by means of vegetable physiology, the study and development of the chick taking its place in Standard VI. The great feature of the syllabus is the application of the lessons where possible by means of inspections, drills, and parades, the senior standard studying the seasonal prevalence of disease in environment, and making visits to museums to view appropriate models. Senior health monitors are also appointed to report on the sanitation of the school grounds. Precept and practice thus go hand-in-hand. Another commendable feature of the scheme is the telling of stories dealing in a general way with the triumphs of hygiene, such, for instance, as the construction of the Panama Canal.

THE METROPOLITAN WATER-SUPPLY DURING JULY, AUGUST, AND SEPTEMBER, 1918.

ALTHOUGH the mean rainfall during the month of July at 12 stations which have been selected as giving equal representation for all parts of the Thames Basin was 2.06 inches above the average mean rainfall for that month during the previous 35 years, the raw river waters showed an improvement in quality judged by chemical examination, but all three raw waters (Thames, Lee, and New River) contained more bacteria than their respective averages for the year 1917. The filtered waters likewise improved in chemical respects, while bacteriological examination yielded, generally speaking, not unsatisfactory results. There were no typical *B. coli* found in 75.3, 43.5, and 74.8 per cent. of the filtered water samples derived from the Thames, Lee, and New River water respectively, even when 100 c.cm. were examined. In August, on the other hand, the rainfall was 1.47 inch, being 1.17 of an inch below the average mean rainfall for that month during the previous 35 years. Though in some particulars not maintaining the chemical quality of the previous month, all three raw river waters yielded results better than their respective averages in 1917, and the same condition is recorded as regards the filtered waters, except that the colour showed less satisfactory results in the case of the New River and Lambeth supplies. There were more bacteria present in the raw water from the Thames and Lee than in 1917, but the bacteriological results of the filtered waters were satisfactory. September was a relatively wet month, the rainfall being 5.86 inches, which is 3.91 inches above the mean average rainfall for that month during the previous 35 years. All three raw waters showed, generally speaking, a deterioration in quality according to chemical examination, but the filtered waters maintained their quality on the whole. The Lee and New River raw waters contained more bacteria than their respective averages for the year 1917, but raw Thames water contained fewer compared with the same period. All filtered waters as they reach the consumer gave satisfactory bacteriological results.

THE "ARELLANO" INFLUENZA MASK.

PARTICULARS are given in our advertisement columns this week of the "Arellano" influenza mask, named after its designer and made by Messrs. John Bell, Hills, and Lucas, Ltd., who were so successful as manufacturers of the poison-gas respirators used in the field by H.M. forces. The Arellano mask has been approved by medical men for its purpose, and will be placed immediately, in large quantities and at a low price, on the market. Our readers know that the use of masks has been suggested as a precaution in more than one quarter during the recent epidemic of influenza.

KHAKI MONOTONY.

"A wearer of khaki," a medical man, who "craves for a little colour" and who believes that "bright colours cheer us on our way through life," calls our attention to the monotony and sombre hue of khaki, and thinks that after more than four years of war the prevalence of this dim tint has a malign influence. There can be no doubt as to the influence of colour on the mind of the savage and of the sophisticated, though the psychological effects may differ in depth and quality, but whether it would really dispel any existing depression caused by the war if, when public and State ceremonials call for military escorts and processions, the soldier appeared in full dress uniform we are not so sure as our correspondent. Probably there are plenty of uniforms stored away which could become available at short notice, so that the authorities could comply with the suggestion without much public expense, but we are not convinced of the utility of doing so. With regard to military displays, and it is to these that our correspondent specially refers, it should be remembered that for the men taking part in them full dress uniform is not the most comfortable in which to remain often for long hours and perhaps with inadequate opportunities for food.

The Examination

OF THE

VERMIFORM APPENDIX BY X RAYS.

BY E. I. SPRIGGS, M.D. LOND., F.R.C.P. LOND.,
SENIOR PHYSICIAN, DUFF HOUSE.

With Photographs and Drawings by
O. A. MARXER,
RADIOGRAPHER, DUFF HOUSE.

I.—INTRODUCTION AND HISTORY.

IN examinations of the human alimentary tract by means of a meal opaque to the X rays, the appearance of the vermiform appendix on the fluorescent screen or photographic plate has been until lately infrequent and uncertain. Although there is already a large literature of the radiology of the alimentary tract, references to the appendix are, as would be expected, scanty.

Béclère, in 1909, showed a radiogram of the appendix, which had been taken at the end of 1906, with a five minutes' exposure. In 1910 Lieritz, and in 1911 H. D. Reid, reported a similar observation. In 1911 Grigorieff communicated to a congress of physicians in Moscow that he had seen the appendix fill with opaque material, move, and empty itself; and stated that with suitable methods it would fill in all cases in which its lumen was in free communication with the cæcum. M. Cohn, who reported observations of his own in 1913, and from whose paper we quote the Moscow communication, thought that Grigorieff's powers of vision were uncanny; but the description given was accurate enough, and can now be confirmed daily. In the same year (1911) A. C. Jordan had observed that a little bismuth entered the appendix in a good many cases.

In 1913 the work of J. T. Case called the attention of A. W. George and I. Gerber to the appendix. These workers, using an opaque meal of barium sulphate suspended in buttermilk, claimed that the appendix could be seen in 70 per cent. of the patients examined, and published photographs. In 1914 A. F. Hurst expressed the opinion that the appendix was visible on the screen, more or less, in half the cases examined, recording two cases of diseased appendices which had been recognised with the X rays, and Rieder advocated a more thorough examination of the appendix. Case (1914) saw the appendix in one-third of a series of 763 cases and published good photographs, but at that time it was thought probable that the appendix was or had been diseased if the contents of the cæcum were seen within it. In 1915, Imboden published 17 photographs of which 7 were probably normal, and expressed the opinion that the demonstration of the appendix was no evidence of disease; and in the same year George, writing this time with Leonard, published good photographs of diseased appendices. Quimby (1913) and Eisen (1915) have also published instructive papers with photographs. Carman and Miller, of the Mayo Clinic, show a few photographs of appendices in their recent excellent work. They speak doubtfully, however, of the value of direct X ray examination of the appendix.

George and Leonard, claimed that with a meal of 90 g. of bismuth, or equivalent of barium sulphate, and one pint of buttermilk the appendix, whether healthy or diseased, unless its lumen be obliterated, can be demonstrated in every instance. Such a claim cannot, of course, be made good, as, short of operation, there is no control means of knowing whether the lumen is obliterated or not. Our observations in the last two and a half years nevertheless enable us to support the view that the opaque meal they use, of barium sulphate and buttermilk, is of great value in the X ray examination of the appendix. With a meal of bread and milk, or porridge, and bismuth oxychloride or barium sulphate, the appendix was often looked for but seldom seen. With buttermilk and barium we now see it in the majority of cases.

II.—METHOD.

We use a rather smaller meal than George and Leonard.

In all cases we have given the same quantity of buttermilk, 3/4 of a pint (425 c.cm.). The amount of barium is varied according to the build of the subject. With a thick body 150 g. is stirred in; with thinner folk less is used. The meal is not so viscid as a standard meal of bread and milk, and holds the barium in suspension better than milk alone. George and Leonard state that cereal mixtures do not readily enter the appendix. Perhaps the absence of milk fat in their meal is also an advantage, or the acidity. The taste of the buttermilk is unpleasant to some, but now that it is

clear that the appendix can be demonstrated more palatable mixtures will be sought, and probably found. As regards the examination of the rest of the alimentary canal, we have not found any disadvantage in the use of the buttermilk mixture, but the reverse. For œsophageal lesions a more solid meal would naturally be given. The normal rate of passage of the buttermilk meal through the body is about 12 to 24 hours less than that of a meal of porridge and barium.

An opaque enema has not proved, either in the experience of others or ourselves, to fill the appendix so often as an opaque meal.

We found over three years ago that the appendix is more frequently seen when the bowel has been emptied by castor oil given 36 hours before the opaque meal.

The manner of examination is, of course, of great importance, as well as the kind of meal and the previous emptying of the bowel, for a careful search and suitable manipulation will often reveal the appendix when it would otherwise have been missed. We would lay stress on the following points:—

1. Careful screening with manipulation is needed to find the appendix, also to observe its mobility and the presence or absence of active movements or of tenderness, that is, pain on direct pressure.

2. Photographs must be taken in all cases: we take frequently half a dozen or more of the same appendix. The chief features which help a decision as to whether the appendix is healthy or diseased can only be observed adequately on the photographic plates. These features are—the filling and emptying of the appendix, its position and its outline.

3. The best views are obtained as a rule when the patient is lying down, usually supine; occasionally the semi-lateral position is required, rarely the prone.

4. The gloved hand is used at first in ascertaining the lie of the parts; for the final movements, the wooden spoon is used because it is not opaque to the rays and a plate can be exposed so soon as the appendix is brought into the field.

5. The ileum and cæcum are drawn aside carefully in different positions so as to get a view of the whole appendix whenever possible. A better contrast is obtained if the appendix can be moved over a part of the bowel which contains air before the photograph is taken.

6. When the cæcum lies in the pelvis the appendix can often be shown, but, generally speaking, its mobility cannot be tested. It is possible, however, in most cases to move the cæcum into the iliac fossa by the following procedure. The patient lies on the right side and takes half a dozen deep breaths, then turns semi-prone on the right, still breathing fully; he then moves on to his back and the abdomen is stroked deeply from the symphysis pubis to the right iliac crest. Another means of moving the cæcum out of the pelvis is to distend the rectum with air, the patient lying on the right side; we have used this method, but have generally found it unnecessary.

7. If the appendix lie behind the cæcum it can often be shown by taking an oblique view or by moving the cæcum to one side.

8. It is an advantage if the end of the ileum and the appendix can be shown filled at the same time. Should there be opaque material in the ileum, but not in the terminal part, it will often be moved on into the terminal part if a drink of hot water be given, provided there is no obstruction to prevent the hot water leaving the pylorus. The patient should turn on to the right side.

9. When there is pain, tenderness, or inflammation movements and manipulations must not be made, or only made with great care.

10. A 2 mm. aluminium screen is interposed for both screening and plate exposures, using a Coolidge tube.

11. In doubtful cases where the appendix fills in part only, or empties before it has completely filled, a succession of buttermilk meals at breakfast, lunch, and tea-time may fill it. The usual amount of barium is divided between the three meals.

The value of (i.) the special meal and (ii.) practice is illustrated by the following experience. The first 100 cases in which we observed the passage of an opaque meal through the alimentary canal are left out of account, as the ileo-cæcal region was not examined with such care as is now given it. In the next 200 cases we saw the appendix clearly in a few. Many of these were prepared with castor oil. We then began to use the barium and buttermilk meal after preparation by castor oil. In the next 100 cases the appendix was seen 24 times, in the following 100 cases 35 times, then 54 times, then 72 times, and in the last, and eighth, 100 cases 86 times.

Observations.—We have now photographs of about 300 appendices, seen in the whole or a part of their length. In

many no evidence of disease was found in the appendix or in its neighbourhood; it was in such that the observations described in Section III. below were made. Others were diseased or in close relationship to diseased organs; these are described in Section IV.

III.—THE NORMAL APPENDIX.

Previous observers, especially George and Gerber, George and Leonard, and Case, have noted that in health the shadow may vary in width from $\frac{1}{4}$ inch down to a thread (Figs. 1, 6, 9, 11, and 12) or a row of dots (Fig. 3); that the lumen may be seen to fill and empty several times, especially in young people; and that it empties finally at the same time as the cæcum. George and Leonard state that it is best seen in the plates taken at 6 hours and at 24 hours after the ingestion of the meal.

As the appendix is often diseased, care is needed before it can be concluded that the appearances seen are not pathological. Clear evidence must be obtained of natural position, mobility, and outline of the appendix and surrounding parts; of a natural rate of filling and emptying of the ileum and cæcum; of the absence of tenderness to direct pressure; and of pain or any symptom suggestive of appendical disease. The mobility of the appendix, so far as it is not limited by its short mesentery, and the absence of tenderness on pressure, cannot usually be determined when the cæcum lies in the pelvis, unless it is, as above mentioned, manoeuvred into the iliac fossa. The distal part of the appendix should be movable within the limits of its attachments, and the whole should move freely with the cæcum. The outline of the healthy appendix should show no constant irregularities.

According to our observations the appendix begins to fill soon after material has entered the cæcum—that is, about 3 to 4 hours after the meal has been taken. It may fill in a few minutes from end to end. Frequently, however, the filling is quite slow and is not observed in process; also it may not take place for some hours after the cæcum and ascending colon are filled. In some cases, with rapid filling, the material entering appears of the same breadth throughout (Figs. 10, 11, and 12), as if it were forced in by higher pressure in the cæcum, and occasionally material may be seen to pass along the lumen when the cæcum is pressed gently. In others temporary constrictions can be seen (Figs. 2, 5, and 8.) We have not actually seen a wave of constriction passing isolated pieces of opaque material from the base towards the apex of the normal appendix, but we have seen material lying loosely in the middle occupy the tip three seconds later, its tail showing a tapered appearance, apparently as a result of a contraction of the appendix, the basal part near the cæcum remaining tightly constricted. In some pathological cases, with over-activity, a definite wave can be seen to propel material from base to apex of the appendix. In such we have observed a block of material moving towards the apex, showing a round head towards the tip and tailed off towards the base where the wave of constriction was grasping it.

Sometimes the appendix can be seen to fill and empty repeatedly during a single screening within a few seconds. This has been most definite in young people; for example, in two subjects aged 16 and 9 respectively (Fig. 5 was taken from one of them). Or it may fill and empty at a slower rate several times in the course of a few hours.

The width of the lumen varies considerably in different appendices and in the same individual; it is usually fully relaxed after fresh material has entered, and becomes constricted later. (See Figs. 31 and 32 taken at an interval of 20 seconds). It bears no proportion to the size of the cæcum and ascending colon. It is usually narrowest at the base—i.e., near the cæcum. (Figs. 6 and 8.)

The time at which the best view is obtained is usually about 12 to 14 hours after the opaque meal, but there is much variation in this respect.

The appendix commonly remains filled until the cæcum is clear, when its contents are discharged. The density of the appendical shadow lessens as the cæcum empties (Fig. 10). In some cases in which there is no evidence of disease the contents remain longer—e.g., until the ascending colon is clear. If there is further delay we regard the appendix as sluggish. The appendix empties itself by waves of contraction which we have seen pass from the tip to the base, propelling material into the cæcum. It may empty while the cæcum is still filled.

In some cases the tip can be seen to wave about actively with a serpent-like motion (Figs. 7 and 8), presumably from contractions of its wall, or from the passing in of material from the cæcum. Such movement of the middle part has also been observed repeatedly at the same time as food was passing from the ileum into the cæcum.

It has been stated that the appendix tends to become gradually obliterated with age. This is not, however, a

necessary accompaniment of advancing years, for in one of our subjects, aged 74 years, in whom the alimentary canal appeared to be healthy in all respects, the diameter of the shadow was greater than that in many young people. (Fig. 10.)

In one patient, in whom the appendix was found healthy, on re-examination 18 months afterwards two pellets of shot were seen within it and could be moved about (Figs. 11 and 12.) They gave rise to no symptoms, but the appendix emptied itself more slowly than before, containing some barium 24 hours longer than the cæcum. The abdomen was screened weekly and three weeks later the pellets had gone. A similar occurrence was recorded by G. H. Orton in 1907, but the appearances were not so distinct, the nature of the foreign bodies casting the shadow being discovered at an operation. The appendix appeared healthy.

IV.—THE DISEASED APPENDIX.

In most cases of acute appendicitis the patient is not fit to be X rayed; neither is such a method of diagnosis needed.

In the diagnosis of chronic appendicitis we have found direct X ray examination of the appendix of great value, not only in cases in which suspicion had been cast upon that organ, but especially in the subjects of vague abdominal symptoms of unknown cause; in many such it has been possible either to demonstrate a normal appendix or to show that it was or had been the seat of disease.

The direct observation of the appendix is only a small part of the complete examination of the alimentary tract, and in many cases in which a suspected appendix has been found normal an explanation of the symptoms is furnished by lesions or disorders discovered elsewhere in the course of the examination. Every part of the stomach and bowel must, of course, be observed carefully. Further, it must be emphasised that all such methods of investigation are supplementary to a thorough clinical inquiry. Indispensable as the laboratory is for the medicine of to-day, it can never replace accurate and exhaustive examination at the bedside.

We have not been situated especially favourably for the observation of cases of chronic appendicitis, as Duff House is for medical cases, and no patient is sent there who is known to be the subject of that complaint. Our cases are therefore of two classes: (1) those in whom the symptoms of chronic appendicitis have not been definite; and (2) patients sent by doctors in the neighbourhood. The latter class is small in numbers, but has the advantage that one of us has frequently been able to be present at the subsequent operation.

In 36 cases we have details of operative findings, and upon these this section is mainly founded. A summary of each is given. Our opinions and conclusions are founded also upon the examination of other cases. We have in all, as stated in Section II., photographs of 300 appendices with a clinical history of each patient.

It is sometimes possible to make a diagnosis of chronic appendicitis from X ray findings in the ileo-cæcal region other than direct observations of the appendix. Such findings as adhesions of parts, ileal stasis, insufficiency of the ileo-cæcal valve, and spasticity of the colon have been put forward as affording contributory evidence of appendicitis. Adhesions about the appendical region are, of course, suggestive of former inflammation. Ileal stasis is an uncertain guide.* It was present in 21 out of 35 cases operated upon; also in cases in which the appendix had been removed. Eisen states that ileal stasis and regurgitation are as frequent in normal cases as in those of appendicitis. To insufficiency of the ileo-cæcal valve and spasticity of the colon we do not attach importance in this connexion. Examination of the appendix itself with the buttermilk meal gives more valuable information in most cases than can be derived from observations on surrounding parts made with those opaque meals which enter the appendix less often.

In the direct examination of the appendix the points to which attention must be paid are: (1) the filling or emptying of the appendix—delay or stasis; (2) shape—constriction.

* Ileal stasis has been said to be present if the terminal ileum is not empty nine hours after the opaque meal. Such a definition can only apply if the stomach is empty in a normal time, for the ileum cannot discharge its contents promptly unless it receives them promptly from the stomach. This fact has sometimes been overlooked and ileal stasis has even been depicted in the literature by a photograph in which opaque material can still be seen in the stomach. As a working definition we speak of ileal stasis or delay if the terminal ileum contains opaque material more than four hours after the stomach is empty.

tion and dilatation; (3) faecal concretions—vacuoles; (4) mobility; (5) hyperactivity—spasm; (6) tenderness; (7) position. These features are placed in the order of their value in a series of cases. In individuals any one feature may be of chief importance.

1. The Filling and Emptying: Delay or Stasis.

The appendix may not admit any barium, or not enough to cast a shadow, either because it already contains inopaque material or because it is obstructed or obliterated. The first is but seldom the case when the bowel has been purged with castor oil. Constriction near the base or obliteration will, of course, account for some of the cases in which the appendix is not seen. (Cases 29 and 30.) The fact that with increasing practice more and more appendices are visible shows that an impervious lumen is much less common than was thought. But we do not think it justifiable in the present state of our knowledge to conclude that an appendix is abnormal because it does not fill; though we should naturally regard it with suspicion, as it is unusual to fail to demonstrate the appendix in a person thought to be normal, especially if a second examination be made with three small buttermilk and barium meals, as described above.

Most frequently in chronic appendicitis the appendix fills in part (Figs. 13, 16, and 18), the passage of barium into the distal part being blocked, sometimes by obliteration (Fig. 20 and coloured drawing, Case 8), or constriction or kinking (Fig. 17), but generally by stagnant inopaque material (Figs. 13, 16, and 18) which the appendix has been unable to expel owing to limitation of movement by inflammation or its results. Sometimes the barium mixes with this material, forming a fainter shadow.

Such interference with the muscular activity of the appendix wall also prevents the punctual discharge of the barium which has entered, so that instead of the appendix emptying at about the same time as the cæcum it retains its contents 12, 24, or more hours longer. We have seen barium remaining for 26 days, and it has been known to remain for several weeks. Sometimes a blob of material also remains in the adjoining part of the cæcum, which forms a sort of antechamber to the appendix.

In cases of moderate appendical stasis without any other abnormal feature such as irregularity of outline, uneven filling, immobility or tenderness, we have not recommended excision; though an appendix showing prolonged stasis is one in which faecal concretions would be likely to form. If the shadow is very fine and the appendix rigid there is probably a fibrous atrophy.

2. Shape: Constrictions and Dilatations.

Irregularity in the outline of the shadow, is, next to uneven filling, the commonest sign of diseased appendix. Care must be taken, by repeating the photographs, to see that the irregularities are persistent and are not due to normal waves of contraction. Many forms of dilatation and constriction are illustrated in Figs. 13, 17, 19, 21, and 22, and in the coloured illustrations.

3. Faecal Concretions; Vacuoles.

Concretions of long-standing become infiltrated with lime salts and cast a shadow which may be seen independently of an opaque meal (Fig. 14). Such a shadow may be confounded with calculi in the urinary tract. It is usually a symmetrical oval which may help to distinguish it from the shadows of calcareous glands and phleboliths. The lumen proximal to an old concretion is often bent into a sharp hook; indeed, a hook-shaped end to the appendical shadow, as in Figs. 14, 18, and 22, should suggest the possibility of a concretion.

More recent concretions, which cast no shadows of their own, may block entirely the passage of barium, in which case they cannot be recognised, though they may be suspected in appendices of irregular outline which fill in part only and show a hook. In Figs. 16 and 18, for example, such concretions lay in the distal part of the appendix which did not show in the photographs. In many cases the barium passes round a soft concretion, which then gives the appearance of a vacuole (Figs. 13, 17, and 18). There may be more than one of these abrupt or gradual widenings of the lumen, which are constant in different photographs, alternating with narrow places. In other cases the barium extends around the proximal part only of the concretion, giving a V- or cup-shaped shadow as in Fig. 13.

4. Mobility.

If the appendix cannot be moved about within the limits of its attachments adhesions are suspected, but if the cæcum and appendix lie in the pelvis this sign cannot, as a rule, be established unless they can be brought into the iliac fossa. Adhesion of the appendix to other parts of the digestive tube can often be shown by manipulation, the adherent parts moving together. Thus the appendix shown in Fig. 23 (Case 12) could not be moved away from the cæcum. It is most often adherent to the iliac fossa, the ileum, the cæcum, or in the pelvis. In Case 2 (Fig. 14) the ragged outline of the ascending colon where the appendix appeared fixed confirmed the suspicion. The appendix may fill with barium, even when it is bound down for the whole of its length, as in Case 17 (Fig. 26), where inflammatory membranes covered the appendix and cæcum and constricted the ileum.

Sharp kinks must be noted carefully, but it is important to take several photographs, for what appears to be a kink in one may prove to be a rounded curve when viewed from another aspect. (See Case 15, Figs. 27 and 28.)

5. Hyperactivity: Spasm.

The normal filling and emptying movements of the appendix, which in the young are, like the mass movements of the colon, often vigorous and rapid, may be aggravated in older people by acute and subacute inflammation in those parts of the appendix in which gross changes have not taken place. In chronically inflamed appendices containing a fixed faecal mass offering resistance to free progress we have observed vigorous waves travelling from the cæcum towards the tip (Fig. 30), but not in the reverse direction, even when barium lay distal to the obstruction. Such hyperactivity was observed in Cases 1 and 14. Figs. 16 and 30 are photographs of appendices during contractions. The drawing here shown was made from an inflamed appendix which showed vigorous contractions apexwards proximal to an obstruction.

Such pathological hyperactivity differs from the normal activity in that it is often continuous for hours during the filling period; we have even seen it still going on at 24 and 36 hours. Whereas the normal movements are only seen, through the good luck, so to speak, of happening to observe the appendix at the right moment. The block of material in the normal appendix also shows as a rule a symmetrical tapering each end, which can be seen in Figs. 2 and 5.

Another characteristic appearance of the inflamed appendix is that of spasm. A particular part remains constricted for a considerable time, the blocks of opaque material being cut off abruptly (Figs. 15, 25, and 33), whereas when they are being moved on by waves of contraction they have tailed or rounded ends (Figs. 16 and 30). Slight or varying dilatation of the lumen is nearly always present also. When concretions are present there is generally no spasm. A very small lesion may cause spasm and impair the rate of emptying. In one case there was spasm at a place where a spray of purple spots in a mucous crevice was afterwards found.†

6. Tenderness.

Tenderness or pain on direct pressure over the appendix shadow may be a valuable and unequivocal sign of inflammation. An enlarged part of an appendix is frequently, though by no means always, painful on direct pressure. But, taken alone, tenderness is of less uniform significance than might be expected. It is not safe to make a diagnosis of appendicitis from tenderness in the absence of the more important signs above mentioned. If direct though gentle pressure is made upon the base of the appendix pain is often felt,

C. Cecum. o. Obstruction. p. Trail of preceding wave of constriction. wave. Abrupt and complete obliteration of the lumen by wave of constriction starting at the vestibule propelling block of material before it.

† In order to avoid confusion between inflammation and trauma the surgeon should take the mesenteric tissue into the forceps during removal, and not the appendix itself.

DETAILS OF 36 CASES IN WHICH THE RADIOGRAPHIC AND OPERATIVE FINDINGS HAVE BEEN COMPARED;
AND INDEX TO FIGURES OF DISEASED APPENDICES.

| Case. | Clinical summary. | X ray. | Operation. |
|-------------|--|---|---|
| 1 (554) | Male, aged 20; had suffered for years from intermittent pyrexia, constipation, diarrhoea, and abdominal pain. Pyrexia had been ascribed to phthisis, evidence of which years before; appendix had not been suspected. | <i>Fig. 15.</i> —9 hours after opaque meal. Appendix lies horizontally, across irregular shadows from ileum, tip near umbilicus. Proximal part filled and showed vigorous contractions. Shadow beyond formed dilatation with irregular cupped or V appearance, due to barium reaching round sides of a faecal mass. This part and base were tender. An hour later proximal part was contracted. At 24 hours all material except a coating had passed from bowel, but not from appendix. At 48 hours still barium in appendix and in adjoining part of caecum. (See also <i>Fig. 13 A.</i>) | Two inflamed enlargements of appendix. (See coloured drawing I.) Barium had reached to first one; acute bend beyond and large bulbous end not shown on plate. First enlargement contained soft solid matter, terminal one hard faecal mass. No appearances of tuberculoles in appendix or surrounding peritoneum. |
| 2 (596) | Male, 36. Flatulence, heartburn, wasting, weakness. 6 years' history; worse last 2½ years. Had been X rayed repeatedly; treated for dilated stomach; advised to have large intestine removed. Appendix not suspected. | <i>Fig. 14.</i> —8 hours after opaque meal. Caecum lies in pelvis. Shadow of material in caecum and ascending colon is interrupted at brim of pelvis. Appendix lay upwards, partly behind ascending colon. Proximal part appears natural. Distal part was large till near end, where narrow curved constriction can be seen, ending at oval concretion; this could not be moved from ascending colon, which had here ragged outline, ascribed to adhesions. (See explanatory diagram.) | Position as shown in photograph. Complete narrow mesentery, loop seen being due to shortening at one part. Appendix somewhat dilated beyond bend; after dilatation there was fibrous constriction and large concretion beyond. Wall enclosing concretion adherent to ascending colon. (See coloured drawing II. Drawing is less than natural size.) |
| 3 (615) | Female, 32. Pain in umbilical region on much exertion; easily tired; bowels irregular. X ray evidence of former phthisis. Appendix had not been suspected. | <i>Fig. 15.</i> —13 hours after opaque meal. Appendix lay upwards behind caecum; it appeared large and somewhat irregular, and showed spasm at all stages. Tip did not fill. | Middle of appendix enlarged, blue and inflamed, tip fibrous. (See coloured drawing III.) |
| 4 (658) | Female, 31. Flatulence, headaches, bad taste; several years' history | <i>Fig. 16.</i> —10 hours after opaque meal. Shadow shown spreading out into dilatation of appendix. Opaque material not seen beyond inflamed area. At 24 hours caecum lay in the pelvis. Appendix is still irregularly filled. It lay upwards; tip bent and could not be moved about; except that the proximal part could be moved as a whole with caecum. In same position at 10, 24, and 36 hours; was tender. No ileal stasis. | Appendix narrowed near base and bent and anchored by short mesentery. Beyond this dilated and congested. (See coloured drawing IV.) |
| 5 | Female, 13. Repeated attacks of severe pain in right iliac fossa. | <i>Fig. 17.</i> —36 hours after opaque meal. Appendix filled imperfectly; kinked, irregular in outline, bulbous tip, tender. Middle part gave faint diffuse shadow such as is seen when opaque material mixes with inopaque. Caecum filled irregularly; no definite notches at any stage; ileal terminal was not seen evenly filled. No ileal stasis. (See explanatory diagram.) | A pericecal membrane. Appendix enlarged, kinked, inflamed; concretions at end, one solid. (See coloured drawing V.) |
| 6 (684) | Male, 44. Indigestion on and off over 25 years. 24 years ago short attack abdominal pain and pyrexia; may have been appendical. On active service in France 3 years, including retreat. Worse last few months. Hyperacidity. | <i>Fig. 18.</i> —36 hours after opaque meal. Caecum lay in usual position of hepatic flexure. "Ascending" colon descended from it in front; then turned to left to become transverse colon. Appendix did not fill well; seen above caecum curled upwards and to right. Bulbous; had hook appearance often seen proximal to concretion. Much delay, material still in appendix at 140 hours. Rest of bowel clear at 72 hours. Kinking of ileum with stasis. | Caecum and ascending colon had each a mesentery. Caecum lay high in loin, ascending colon depending from it in front. Appendix long, congested, bulbous, and contained concretions. (See coloured drawing VI.) |
| 7 | Male, 45. Symptoms of hyperacid indigestion for years. | <i>Fig. 19.</i> —8 hours after opaque meal. Outline of appendix irregular. X ray evidence of duodenal lesion. No ileal stasis. (See also <i>Fig. 19 A.</i>) | Appendix bulbous, adherent, contained concretions. (See coloured drawing VII.) Ulceration or cicatrization of duodenum. |
| 8 | Male, 54. Ten years' history of hyperacid type of indigestion, flatulence, and distension in right iliac fossa three hours after food. | <i>Fig. 20.</i> —24 hours after opaque meal. Appendix seen filled imperfectly at all stages; emptying much delayed. Terminal ileum anchored to iliac fossa; great delay in ileum. | Tip of appendix fibrous. (See coloured drawing VIII.) Lane's kink in ileum. |
| 9 (713) | Male, 38. Occasional attacks of indigestion for over 20 years. Hyperacidity. | Proximal part of appendix much dilated. A little diffuse barium seen to enter distal part 4 hours earlier does not now show; it appeared packed with stationary faecal matter. Material delayed in dilated proximal part of appendix and adjoining part of caecum after rest of bowel was empty. Also X ray evidence of lesion of duodenal cap. | Appendix bound down; constriction near middle. Also a hard scar in first part of duodenum. |
| 10 | Female, 18. Pain after food; much worse at periods. | <i>Fig. 21.</i> —10 hours after opaque meal. 1 regular bulbous appendix; delayed emptying; no tenderness; ileal stasis. | Appendix ½". Signs of recent inflammation—e.g., thickened mucous lining and injected subperitoneal vessels. |
| 11 (826) | Female, 25. Attack of abdominal pain, tiredness, and anorexia six weeks before, succeeded as it passed off by pricking pain in right iliac fossa. | <i>Fig. 22.</i> —24 hours after opaque meal. Appendix has irregular outline, proximal part much the larger at all stages. Hooked appearance associated with concretion shown. No tenderness. Ileal stasis. | Whole appendix x thickened; three concretions. |
| 12 (788) | Female, 36. Occasional attacks of epigastric discomfort, with vomiting, for years. Three days before admission more severe gnawing ache, pyrexia, rapid pulse, and furred tongue. Tenderness to right of umbilicus. | <i>Fig. 23.</i> —6 hours after opaque meal. Appendix filled unevenly; irregular outline, constriction. Proximal part not mobile; tender. Appearance constant. Terminal ileum on right of picture; ileal stasis. <i>Fig. 24.</i> —At 36 hours. Stenosis at junction of middle and proximal third. Distal part now filled better; irregular outline; spasm near end. Dropped transverse colon lies to right of picture. | Operation 7 days later. Appendix partially bound to caecum near base and kinked; bulbous end. It had appearance of subcutaneous inflammation. |
| 13 | Male, 25. Pain and tenderness in right iliac fossa. Had vomited twice. | <i>Fig. 25.</i> —14 hours after opaque meal. Appendix showed irregular outline, spasm, and tenderness. No ileal stasis. | Very long appendix. Two patches of inflammation of mucous membrane. |
| 14 | Male, 14. Two mild attacks of appendicitis. Headaches. | <i>Fig. 29.</i> —10 hours after opaque meal. Appendix showed irregular outline, contracted vigorously; was tender. End of appendiceal shadow seen spreading. Ileal terminal appeared incapable of normal dilatation at all stages; much stasis. | Appendix had been inflamed, constricted by band; was narrowed near base, dilated at middle part. Ileum bound down. |
| 15 | Female, 37. Had had dysentery. Sought advice for loss of flesh and appetite. Mild indigestion. | <i>Fig. 27.</i> —8 hours after opaque meal. Appendix showed constriction, constant, near base. Terminal part seen to contain inopaque material. Some ileal stasis. <i>Fig. 28.</i> —At 8½ hours. Shadow of appendix shows that what appeared kink in <i>Fig. 27</i> is rounded curve. Sharp bend in ascending colon, which is fastened to transverse colon; irregular segmentation in both. Calcareous glands seen; | Appendix showed constriction; large bowel bent and adherent as described. Calcareous glands were removed. |

* The appearance was not altered by gentle pressure, as is sometimes possible when blockage is due to soft matter or bubble.

DETAILS OF 36 CASES IN WHICH THE RADIOGRAPHIC AND OPERATIVE FINDINGS HAVE BEEN COMPARED;
AND INDEX TO FIGURES OF DISEASED APPENDICES—(Continued).

| Case. | Clinical summary. | X ray. | Operation. |
|-------------|--|--|--|
| 16 (275) | Male, 45. Patient X-rayed 18 months before. Meal of porridge, milk, and barium. Appendix not seen. | Long curled appendix seen lying external to cæcum. Ileal stasis. | Operation a year later; appendix found as described. Calcareous gland in its mesentery close to appendix wall, causing bend in proximal part; vessels in this region somewhat injected. |
| 17 | Male, 30. Acute appendicitis 12 years ago; appendicectomy refused. Milder attacks followed; increasing constipation; frequent distension after food. Condition becoming grave. | <i>Fig. 26.</i> —10 hours after opaque meal. Appendix retro-cæcal and fixed, but position could be made out and is shown in explanatory diagram. Whole region tender. Terminal ileum constricted; enormous dilatation of ileum behind constriction; marked stasis. | Terminal ileum, cæcum, and appendix were wrapped tightly in inflammatory tissue thought to have arisen from disease of appendix. Ileostomy was done as temporary measure, but issue was fatal. |
| 18 (685) | Male, 59. Patient sought admission for severe pain. Hyperacidity; X ray evidence of lesion about pyloric region. | Appendix showed two constant narrowings and hooked appearance; material remained in it at 72 hours, cæcum having discharged its contents. Ileal stasis. | Pylorus adherent to gall-bladder and liver. Appendix contained two hardened masses of faeces, one fixed and one movable. |
| 19 (619) | Discomfort after food 4 months. Hyperacidity. Symptoms improved with treatment. Six weeks later pain and tenderness in right iliac fossa for 24 hours with pyrexia. | Appendix kinked at middle where outline was irregular; it appeared fixed, though moving freely with cæcum. Tip did not empty its contents for over 12 hours after cæcum. No ileal stasis. | Appendix inflamed. |
| 20 | Male, 60. 15 years' history of excessive flatulence after food. | Proximal part of appendix was kinked and irregular in outline. Much ileal stasis. | At operation appendix adherent to ileum and kinked. Jackson's membrane and Lane's kink. |
| 21 | Female, 12. Periodic bilious attacks. | Appendix showed persistent bulbous appearance; constriction beyond. No tenderness. No ileal stasis. | Showed dilatation and constriction. |
| 22 | Female, 22. Nutrition poor; occasional bilious attacks; vomiting; no pain. | Base only of appendix seen. Ileal stasis. | All appendix except first inch bound down. A Lane's band. |
| 23 | Male, 38. Symptoms suggested duodenal ulceration. | Appendix appears fixed along inner border of cæcum. X ray evidence of duodenal ulcer. | Duodenal ulcer. Appendix adherent as described, and extended about half-way up ascending colon. Otherwise it appeared healthy inside and out. |
| 24 | Male, 12. Recurrent attacks of vomiting; a little pain. | Cæcum lay under ribs. Appendix appeared kinked. It contained chiefly air, could not be displaced; was tender. No ileal stasis. | Appendix lay as described. It was kinked by band of adhesions and had been inflamed. |
| 25 | Male, 65. Long-standing pain in right side of abdomen and constipation. | Appendix retro-cæcal and fixed; otherwise appeared normal. Ileal stasis. | Appendix adherent behind cæcum. Jackson's membrane. |
| 26 | Female, 27. Indigestion, constipation, and anæmia. Had been treated as case of gastric ulcer. | Appendix lay behind cæcum. Ileal terminal filled irregularly; much delay therein. | Retro-cæcal appendix adherent to terminal ileum. Stomach normal. |
| 27 | Female, 42. Symptoms of duodenal ulceration. | Appendix filled in part only; not tender. X ray evidence of duodenal lesion. No ileal stasis. | Duodenal ulcer. Appendix had been inflamed and was kinked. |
| 28 | Female, 28. Pain in right side of abdomen near ribs, going round to back. | Very little opaque material passed into appendix. Some ileal stasis. | There were adhesions between appendix and terminal ileum. |
| 29 | Male, 10. Not thriving; occasional bilious attacks; vomiting. No pain. | Appendix not seen. Ileal stasis. | Appendix kinked and not patent. |
| 30 | Male, 50. Symptoms of duodenal ulceration. | No barium seen in appendix. No ileal stasis. | Duodenal ulcer. Appendix was represented by fibrous cord. |
| 31 | Female, 18. Intermittent pain in right side radiating to back, never acute; constipation and poor appetite. Tender spot on palpation. | Appendix showed irregular bulbous outline; was tender. Ileal stasis. | Appendix dilated in places; had been inflamed. |
| 32 | Male, 42. Pain to right of umbilicus relieved by emptying bowel. Constipation. Had had appendicitis 17 years before. Dilated ascending colon. | Only first part of appendix filled; this was tender on pressure. | Old and recent adhesions about appendix which was patent for about an inch. Distal part obliterated. |
| 33 | Female, 16. Recurring abdominal discomfort with indigestion. Six weeks ago pain in right iliac fossa and rise of temperature. | Proximal part of appendix irregular; spasm seen beyond. Distal part kinked. Material remained in appendix for 20 days. | Appendix loosely anchored to brim of pelvis. Distal part kinked; contained concretions. |
| 34 | Male, 19. Indigestion several years; periodic attacks of pain in abdomen, especially to right. Bouts of diarrhoea and constipation. | Appendix lay behind cæcum, filled irregularly, and appeared rigid. | Appendix lay behind cæcum and showed irregular narrowings. |
| 35 (823) | Female, 37. Ten years' history of epigastric pain two hours after food, flatulence, and constipation. Recently nausea, salivation, and retching after exertion. Gastric juice hyperacid. | Proximal part of appendix dilated, with narrowing beyond; narrow portion appeared fixed and kinked. Tip reached to middle of spine. Crater of gastric ulcer seen on lesser curvature, and arrest of peristalsis. | Appendix long, kinked, and contained large concretion at distal end. Gastric ulcer on lesser curvature of stomach. |
| 36 | Female, 28. Periods of diarrhoea since childhood. In last five years flatulence, heartburn, general discomfort, irritability, and depression. Mucus in stools at times. | Appendix much dilated; spasm at one point, with small projection beyond. Distal part did not fill. Material remained at 72 hours when rest of bowel was clear. | Appendix hypertrophied and wall oedematous. Several concretions. |

Figures from Cases Not Operated Upon.

Fig. 30, No. 587.—Male, aged 70. 12 hours after opaque meal. The appendix had an irregular outline and showed great over-activity, waves of contraction passing material continually from the base towards the tip. The waves ceased where the appendix became bulbous. Ileal stasis. The patient had periodic indigestion with vomiting, but had recently had the prostate excised. No further procedure was advised at present.

Fig. 31, No. 792.—Male, aged 48. 7 hours after opaque meal. Early stages of filling with wide lumen.

Fig. 32.—The same. 20 seconds later. A narrow curved tip can be seen. There was a little ileal stasis.

Fig. 33, No. 480.—Male, aged 49. 9 hours after opaque meal. The appendix shows a dilated proximal part with hook appearance, and is abruptly bent. Spasm. It is tender. The patient is subject to cramping pains on the right side of the abdomen. There were reasons against operation, but he was advised that he must not go far away from the possibility of surgical help. There was a little ileal stasis.

Fig. 34, No. 689.—Male, aged 50. 48 hours after opaque meal. Retro-cæcal appendix with irregular outline. Stasis; the cæcum is partly empty. At 96 hours when the rest of the bowel was clear there was still a residue in the tip of the appendix. No ileal stasis.

Fig. 35.—Female, aged 14. 120 hours after opaque meal. Stasis. 28 days later the opaque material was still to be seen in the appendix.

usually at the spot pressed upon, but sometimes in the left side of the abdomen. The temperament and general condition of the patient must never be forgotten in interpreting this sign.

In a case of serious gastric disorder the appendix lumen was large and filled and emptied naturally, but the patient complained of severe pain when it was pressed upon gently.

He was X rayed again after a fortnight, the same sign being obtained several times in each series of observations. In recommending immediate exploration of the stomach the opinion was given that the appendix was inflamed. At the operation the stomach was found to be the seat of a growth, but the appendix was healthy. This is the only case so far in which we have thought the appendix to be diseased and it has not proved to be so at operation.

INDEX TO FIGURES OF NORMAL APPENDICES.

In all the figures the observer is facing the patient. The observer's left is, therefore, the right-hand side of the body.

Fig. 1. Male, aged 12. 8 hours after opaque meal. The appendix is S-shaped, lying between the cæcum, on the observer's left hand, and the terminal ileum, on the right. The little projection just below where the shadow of the appendix leaves the cæcum is due to a wave of contraction in the part of the cæcum from which the appendix arises. This wave was seen to be travelling appendix-wards. The apparent gap in the shadow of the ileum, opposite the appendix tip, is due to a wave of contraction forcing the contents of the ileum towards the cæcum.

Fig. 2 (No. 570). Male, aged 47. 9 hours after opaque meal. The shadow of the transverse colon lies to the observer's right.

Fig. 3 (No. 559). Male, aged 58. 7 hours after opaque meal. Semi-lateral view from the patient's left. The appendix lies behind the cæcum. See explanatory diagram.

Fig. 4 (No. 514). Female, aged 23. 6½ hours after opaque meal. The cæcum lies in the pelvis. The ileum is seen descending in the middle line to join it. The appendix lies to the left of the middle line.

Fig. 5. Female, aged 16. 24 hours after opaque meal. The cæcum is in the pelvis and the appendix in the iliac fossa. It was seen to fill and empty several times, and was movable. The dark mass to the observer's right is the sigmoid flexure. At a subsequent operation this appendix was seen to be normal. See explanatory diagram.

Fig. 6. Female, aged 37. 10 hours after opaque meal. The appendix shows a dotted appearance, from the alternation of opaque and inopaque material. See explanatory diagram.

Fig. 7. To show movement of the appendix. The same subject as Fig. 1. Two successive exposures were given within one second on the same plate. The blurring of the shadow as compared with Fig. 1 shows how the tip was waving. This photograph was taken three seconds after Fig. 1. A comparison of the two shows also changes in the outlines of the ileum and cæcum due to contractions.

Fig. 8. To show movement of the appendix. Male, aged 11. 24 hours after opaque meal. Two exposures within one second. The blurring of the tip shows movement. A wave of contraction, appendix-ward, is taking place in the part of the cæcum from which the appendix arises. The proximal part of the appendix is contracted.

Fig. 9. The same subject. One exposure three seconds later than Fig. 8. No contraction is visible in the part of the cæcum from which the appendix arises. The proximal part of the appendix is now relaxed and filled with opaque material.

Fig. 10 (No. 569). Male, aged 74. 60 hours after opaque meal. The appendix shows no diminution of lumen on account of age. At 72 hours the appendix and cæcum were empty.

Fig. 11 (No. 493). Male, aged 34. 7 hours after opaque meal. Two shot may be seen in the end of the appendix. See explanatory diagram.

Fig. 12.—The same subject at a later stage. The pellets lie separate in the end of the appendix, which is now curled up. See explanatory diagram.

7. Position.

The position of the appendix in the abdomen depends, of course, upon that of the cæcum. Rare cases are found in literature in which the cæcum lay in almost every part of the abdomen. We have three times found it high up in the right loin, the "ascending colon" descending from it before crossing the abdomen as the transverse colon. The shadow of the appendix could be seen projecting upwards above the cæcum. In two of these patients (Fig. 18, Case 6; and Case 24) the appendix was diseased; in the other it was healthy.

The position of the appendix in relation to the cæcum may vary a good deal, and an unusual position is not necessarily evidence of disease. In 49 cases described or illustrated in this paper there were 7 retrocæcal appendices; of these, 5 gave evidence of deficient filling or discharge or other abnormality. (Figs. 14, 15, and 34.) According to George and Leonard, a retrocæcal appendix, if normal, should be freely movable.

RADIOGRAMS OF NORMAL APPENDICES.

RADIOGRAMS OF DISEASED APPENDICES.

RADIOGRAMS OF DISEASED APPENDICES.

We may summarise the above by saying that the signs of present inflammation are, in addition to pain and other clinical symptoms, a tender point and varying dilatation of the lumen from hyperactivity and spasm, whilst evidence of former disease, recent or remote, is given by concretions, abnormal outline, delay in filling or emptying, adhesions, severe kinks, and, in certain cases at least, by the absence of a shadow.

Photograph of concretion from Case 2, see Fig. 14, also coloured drawing.

CASE 2.—C, Caecum. Ca, Ascending colon. It, Ileal terminal. bl, Bulb containing concretion. cn, Constriction. f, Fixed portion of loop. r, Ragged outline.

CASE 5.—Ab, Appendix base. Abt, Its bulbous tip. Ap, Its proximal portion. b, Diffuse appearance of barium traversing the first bulb. k, Site of kinking. C, Caecum.

CASE 17.—A, Appendix. Ab, Its base. C, Caecum. In, Inopaque material. I, Ileum. ItD, Dilated ileal terminal. ItO, Obstructed ileal terminal. k, Site of kinking if erect posture is assumed. r, Ragged outline of terminal; site of adhesion to caecum.

Of the last 100 cases examined, in 40 the appendix appeared to be normal, though one of these showed tenderness. This was the case above mentioned, in which the patient was ill owing to a growth of the stomach. In 19 cases the appendix was reported diseased; 11 of these have already been operated upon and the diagnosis confirmed. In 27 slighter abnormalities were found, such as appendical stasis (18 cases), kinking, fixation, partial obliteration or diminution of lumen. In the remaining 14 the appendix was not seen. One of these has been operated upon and a constriction found at the base of the appendix.

We wish to express our thanks to the surgeons who have kindly informed us of the condition of the appendices excised by them, especially to Dr. Manson Fergusson, of Banff (17 cases), Dr. J. C. Galloway, of Banff (5 cases), and Professor J. Marnoch, of Aberdeen University (7 cases). We are also indebted to Mr. Gilbert Barling, Sir Arbuthnot Lane, Mr. Hugh Lett, Sir Berkeley Moynihan, Mr. H. S. Pendlebury, Mr. J. H. Pringle, Sir Harold Stiles, and Professor Alexis Thomson.

SUMMARY.

1. It is possible to observe the appendix with the X rays, in the large majority of cases, by the use of an opaque meal of buttermilk and barium sulphate after preparation with castor oil. An account is given of the methods and manipulations which have been found useful in the examination of 300 appendices.

2. The normal appendix fills and empties about the same time as the caecum. It may, especially in young people, fill and empty repeatedly, while the caecum remains full. The best view is usually obtained about 12 to 14 hours after the opaque meal. Twelve photographs of normal appendices are shown.

3. Direct X ray examination of the appendix is of much help in the diagnosis of chronic appendicitis. With adequate observation it is found that the proportion of cases in which no barium sulphate enters the appendix is small.

4. In determining whether the appendix is or has been diseased attention must be paid to filling and emptying, shape, mobility, position, and the presence of concretions, hyperactivity, spasm, or tenderness. Continued contractions and spasm are associated with active inflammation. The existence of a tender point is a valuable sign, but requires care in its interpretation.

5. Details are given of 36 cases in which the X ray reports are compared with the operative findings. In all of these the diagnosis was verified at the operation. Twenty-three photographs of diseased appendices are shown and eight coloured drawings of appendices after removal.

Introduction.

IT is the aim of this paper to analyse the results following upon 131 consecutive urgent operations for acute disease of the appendix; to discuss and, if possible, to elucidate some of the apparent incongruities between physical signs and pathological findings; to offer some observations upon the variations in the anamnesis; and, last of all, to direct special attention to a large and homogeneous class of case in which the origin of the disease and its morbid anatomy are primarily and directly due to obstruction.

This list of cases includes operations performed in the most unpromising surgical surroundings, both in respect of the operation itself and of the subsequent nursing, though there seems to be often more risk in the removal of a patient in certain types of the disease than in operating where few facilities are at hand and many things must be improvised. It is not the actual operation which is severely handicapped, but rather the subsequent nursing of the case—if, for example, it be found necessary, as indeed it often is in such cases, to drain the abdominal cavity. Removal of a patient may entail serious risks in that (1) it delays the operation; (2) it may provoke rupture of a thin-walled gangrenous appendix; (3) it may cause a localised abscess to burst and thus infect the general peritoneal fluid; or (4) it may cause direct extension of infective material into the subphrenic region. Where removal must be faced this should be carried out in the Fowler position (Crawford Renton).

Let me call attention here to the frequency with which pus is met with in cases demanding surgical interference. Out of the 131 cases, no less than 84 had already gone on to suppuration. It was Finney who said:—

"The presence of pus in an appendicitis operation is *prima facie* evidence of a mistake on the part of somebody, the patient, the physician, or the surgeon."

In my own series all excepting one, and that one already perforated, were operated on as soon as seen. In my opinion pus is due not so much to a failure to recognise that the appendix is at fault as to a failure to recognise by its symptoms and signs the grave type of the disease in its early stage. And this suggests the question of diagnosis—often easy, but not seldom difficult, and at times well-nigh impossible. It is not enough to arrive at the conclusion in any case that the appendix is at fault, though this is, of course, the first step, but we should also aim at deciding whether it be a case of (1) acute appendicitis or (2) acute appendicular obstruction. If the latter, what is the condition of the appendix wall? Is it gangrenous, with perforation imminent? or has perforation already occurred and is there pus present, and, if so, is the pus encapsuled or is there infection of the general peritoneal contents?

If the appendix be gangrenous, and if perforation be close at hand, then only the gravest disadvantages will justify delay in operating. Mr. Robert Campbell, in first directing attention to acute appendicular obstruction, showed what a dangerous form of the disease it was—that it has a definite course, extending usually for a period of not less than 36 hours before perforation, and after perforation it has a very grave issue, for the contents of the distended appendix

are under considerable pressure, and when rupture occurs the pus is often sprayed far and wide throughout the general peritoneal cavity. It was to this type of the disease, doubtless, that Sir Berkeley Moynihan referred in his vivid picture of the effect of the homely dose of castor-oil which usually anticipates by some hours the arrival of the surgeon, precipitating a calamity which it is his aim to avert, and transforming an aseptic operation field into a veritable quagmire.

The series under review has been divided up as follows:—

1. True acute appendicitis—34 cases.
2. In edute—10 cases, which from insufficiency of evidence I was unable to classify either as inflammatory or obstructive.
3. Acute appendicular obstruction—87 cases, which have been subdivided further into—
Stage I. Obstructed only (10 cases);
Stage II. Obstructed and gangrenous (18 cases); and
Stage III. Obstructed, gangrenous, and perforated (59 cases).

Each group of cases has been arranged in sequence according to the interval of time between the appearance of symptoms and time of operation.*

True Acute Appendicitis.

The following case is an example of acute appendicitis:—

CASE 30.—Patient, man aged 24, otherwise healthy, was seen with Dr. G. F. Campbell on July 17th, 1913. He had taken ill about eight days before, with feeling of sickness, especially after meals. No actual vomiting; nausea persistent and distressing. The bowels became sluggish. He had a varying amount of pain, worse in evening and at night, and sometimes had to be relieved by poulticing. He had suffered from indigestion for some years. Pulse was 100, temperature 99° F. There was a tender point just internal to anterior superior spine on the right side; small phlegmon present. Operation through right rectus incision; appendix inflamed with thickened walls, lying external to caecum and buried in plastic lymph. No pus; abdomen closed in layers without drainage.

I would especially direct attention to the indefinite onset, to the absence of any great pain as initial symptom, and to the absence of troublesome constipation. Many of these cases, however, go on to suppuration. These are cases of acute appendicitis in which, from the onset, the temperature and the pulse are elevated, and in which pain, though present, is not of such a severe type as in the cases due to obstruction, and even from its first beginnings is definitely localised to the right iliac fossa. In these cases, too, vomiting and constipation are not troublesome, and if pus be present it is small in amount and well walled off by the surrounding organs, which are adherent to the appendix and the caecum. The walls of the appendix are thick and fleshy and there is no distension of its cavity.

In this, the commonest type of acute appendicitis, if perforation occurs it is of less importance than in the obstructive cases for two reasons: (1) There is but little material within the appendix, no distension of its lumen, and therefore no increase of tension; and (2) the appendix is well surrounded by adhesions. Mention must be made, however, of those inflammatory cases in which perforation, if not the first, is an early symptom of disease. In such cases, no doubt, obstruction plays a prominent part, but the group about to be described under the term acute appendicular obstruction is so definite, so large, and so important from the point of view of prognosis that we do not include those cases in it. In one case (No. 2) perforation occurred so early that it can only be explained by antecedent ulceration, which had so thinned the wall that the slightest increase in tension produced rupture.

Indefinite cases.—To this group I do not wish specifically to refer, except to say that so far as they could be examined the more serious cases showed considerable evidence of being primarily obstructive in origin.

Acute Appendicular Obstruction.

I have come across 89 cases of acute appendicular obstruction, of which 10 showed obstruction only, 18 showed obstruction with a varying amount of gangrene of the wall, and in 59 rupture of the appendix had followed the gangrene. A typical case from the third stage of this group is as follows:—

CASE 99.—Youth, aged 19; taken suddenly ill on Dec. 28th, 1915, with very severe pain in stomach; he vomited three times that evening. His bowels till then regular, became constipated. He was seen next morning by Dr. Robert Boyd. Patient complained of pain in left hypochondriac region. Pulse and temperature normal. Slight rigidity over right rectus below. Breath was foul, and tongue thickly coated; otherwise he looked well. The next day he was again seized with a

* From pressure on space, the schedule of cases could not be printed.

sudden severe pain, now localised to right lower abdomen. Temperature 99°, pulse 100. I was asked by Dr. Boyd to see him, and diagnosing a perforated gangrenous appendix, had him removed to the Royal Victoria Hospital, where, through the kindness of Mr. A. B. Mitchell, I was allowed to operate upon him. Operation under open ether; right rectus incision. Appendix found gangrenous for about 2 inches from tip; large perforation, size of a sixpence, lying in abscess cavity containing about an ounce of pus. Appendix removed, cavity drained; good recovery.

The foregoing is a type representative of a very large percentage of the critical cases which a surgeon is called upon to see. They are, so far as my experience goes, the most serious of all the common emergencies in abdominal surgery, and consider for a moment what the pathology of this case was. I make no apology for quoting briefly from the recent experimental work of Mr. D. P. D. Wilkie, who demonstrated the pathological changes which take place in an isolated loop of small intestine into which some caecal content has been introduced, the loop being completely obstructed and there being no interference with its blood supply:—

"When the loop is filled moderately full with caecal content, the animal having been fed on a carbohydrate diet (porridge), distension occurs with fetid faeculo-purulent fluid, and either an empyema of the loop results or a gangrenous patch develops with perforation. With the loop filled with caecal content in an animal previously fed on a rich protein diet (light) the changes are much more striking, and as a rule the animal is dead within 20 hours. On opening the abdomen post mortem the loop is seen to be green and gangrenous."

These are the changes which occur in an occluded piece of animal's intestine, and similar changes occur when the human appendix becomes obstructed at or near its base. The lumen beyond the obstruction becomes rapidly distended with faeculo-purulent material and localised patches, or the whole organ may become gangrenous, to be followed later by rupture.

A consideration of Wilkie's experiments, our own experience of the morbid anatomy of cases seen in the earlier stages, and the appearances found at the operation, agree in indicating that in the above case the symptoms arose from an obstruction near the base of the appendix; that there was present within the appendix a certain amount of faeculent matter; that this obstruction led to gangrene of the appendix; and that, following the gangrene, perforation had supervened. If, then, this be the pathology, and if the appalling mortality in acute diseases of the appendix be due to this type of case, then obviously the remedy lies in diagnosing the condition before perforation occurs; in other words, had one been able to foresee that, in spite of the normal temperature and normal pulse, there lay interned within his abdominal cavity a sloughing appendix, then no excuse would have justified us in allowing perforation to take place.

That this is no unusual type of case, and that symptoms and signs are often unalarming on the second day, numerous arguments and examples go to prove. Here is another:—

CASE 100.—On Dec. 8th, 1914, at the Royal Victoria Hospital, I was asked by Mr. A. Pullerton to operate upon a boy, aged 10, just admitted to hospital. He had taken ill on Dec. 6th. He had been seen on the second day by his own doctor, who was present at the operation, and who told me that the boy suffered considerable pain on Dec. 6th but on the 7th he was so much better that he thought that he might be able to do without operation. On the night of Dec. 7th he was again attacked by acute pain, and when the doctor saw him next morning he sent him straight into hospital. On admission temperature 98°, pulse 122. Large area of dullness present on right lower abdomen. Operated on by gridiron incision, pus released, and tube placed in abscess cavity.

The boy's condition precluded the removal of the appendix, but there can be no reasonable doubt that this case was identical with the one already quoted.

Causation of Obstruction of Appendix.

In these obstructive cases it is our contention that the primary cause of the disease is obstruction of the lumen of the appendix. On examination of the appendices removed at operation it is found that obstruction may be due to one of five causes:—(1) Concretions; (2) strictures; (3) kinks; (4) bands; (5) worms, fruit-seeds, and other foreign bodies.

Concretions are by far the commonest form of obstruction, especially in those cases which go on to the production of gangrene: in my series they were present in about 50 out of 87 obstructed cases. In cases of completely gangrenous appendix coproliths will be found dividing the healthy from the diseased portion, and in the early stages where gangrene is not evident outside it will be found on opening the appendix that the mucous membrane of the distal portion is sloughing. It is no uncommon thing to find, besides the obstructing concretions, several others lying

within the cavity of the appendix. After perforation one or more concretions may escape into the abscess sac, and in one case (No. 119) the abdominal wound healed completely over such a foreign body, which was only found at the subsequent operation for the removal of the appendix.

The exact relationship of these concretions to the disease has not hitherto been definitely established. In our opinion they are the definite *causa causans* of the particular form of the disease now under discussion. They act by suddenly blocking the lumen of the appendix and, by preventing the return of the contents of the appendix into the caecum, give rise to the acute symptoms of pain in the upper abdomen and vomiting already referred to. If the obstruction be not relieved, and more especially, as has been shown by Wilkie, if the patient has been fed chiefly on proteid food, the vitality of the appendix rapidly falls, and in from 30 to 40 hours sloughing supervenes.

Strictures.—The second form of obstruction to which I would direct attention is stricture, of which at least six examples were met with. I first observed this in Case 54. I find that strictures of the appendix have been well recognised and described for many years, notably by Abbé, of New York, and others. These have been attributed by Runyon, as quoted by Kelly and Hurdon, to previous attacks of appendicitis with ulceration, in which the mucous lining of the appendix has been destroyed. In Case 54 the boy had never previously suffered from any form of disease, and it may therefore be an example of what Lenzmann and Ewald have described as *appendicitis larvata*. It adds a further argument to the hypothesis of obstruction by proving that inflammatory changes, even to the extent of ulceration, may take place without arousing the suspicion of disease in the mind of the patient.

I saw another case in which stricture and concretions were combined. This was Case 69, in which an ordinary third-day perforated gangrenous appendix was found. I showed this to Professor J. Symington, and on his advice it was first hardened in formalin, then cut with a razor till we found the exact position of the stricture. This strictured area we then prepared in the ordinary way for microscopical examination. It showed a mass of newly formed granular tissue filling up the lumen of the appendix. It was continuous with the submucous coat and no trace of mucous membrane could be found. Since then Dr. W. W. D. Thomson has kindly investigated the appendix from Case 82.

This was a typical case in which soon after the administration of a dose of castor oil on the second day the patient, a boy of 16½ years, was suddenly seized with pain in the right iliac region. Next day, at operation, we found an appendix obstructed by two complete strictures. Between the strictures the appendix was completely gangrenous and at one point a perforation big enough to admit a slate pencil was found.

FIG. 1.—Outline drawing of an appendix showing position of two complete strictures at 1 and 2.

A line drawing of this appendix is shown in Fig. 1, and Dr. Thomson has gone fully into its pathology and reports as follows:—

Naked-eye appearance.—The cavity of the appendix is divided by two strictures into three compartments. The proximal compartment is continuous with the cavity of the caecum. Its mucous lining and submucous tissue are alike normal. The middle compartment is completely gangrenous and perforated. The distal compartment is full of pus.

Microscopic appearances.—Serial sections were prepared:—

1. The strictures are both complete. Each is formed of a dense mass of granulation tissue which completely replaces the lumen, epithelial lining, and mucous coat of the appendix. It is continuous with the submucous layer. A photomicrograph of this section is shown in Fig. 2.
2. A section through the middle compartment shows necrosis of all the layers of the appendix, with a ragged perforation at one point.
3. The terminal compartment is swollen, tense, and filled with purulent material swarming with *Bacilli coli*.

Kinks.—The third form of obstruction is that due to a kink which is produced by the contraction of an adhesion between two adjacent parts of the appendix. In this way a sharp angularity is formed. Both ends of the adhesion take their attachment from the appendix.

Bands.—A similar angularity may be caused by a band one end of which is adherent either to the parietal peritoneum or other part of the alimentary canal and the other to a proximal part of the appendix. Contraction of this

band causes the appendix to be drawn out to a sharp angle which interferes with the free passage of the appendicular contents.

In obstruction due to bands and kinks the progress of morbid change is generally slower than in the case of concretions, and so, by giving time for the production of protective adhesions, lessens somewhat the gravity of peritonitis, if and when it appears.

FIG. 2.—Section through stricture at 2. Photo-micrograph.

Foreign bodies, such as intestinal worms, fruit-seeds, &c., are rare forms of obstruction.

Stages of Acute Appendicular Obstruction, with Illustrations.

The late Mr. Edmund Owen, in his book "Appendicitis," makes the deliberate statement that no surgeon of experience pays much attention to history. Rarely can such a statement be justified, least of all in acute disease of the appendix in which there is a well-defined sequence of events and a very definite symptom-complex. It is this symptom-complex which I wish to consider now, and by comparing it with appendices removed at the different stages of the disease to correlate symptoms and signs with pathological findings. There may still be some doubt as to whether in any particular case obstruction did or did not exist in the case of bands or kinks; no such doubt can arise with a concretion which blocks like a ball-valve the appendicular canal. All the examples which I show depend on this cause for the obstruction. Fig. 3 shows a typically obstructed appendix. It is a section of the appendix from Case 58, distended with gelatin and cut longitudinally.

It is difficult from a consideration of preserved specimens to get even the faintest idea of the course and stages of the disease owing to the rapidity with which the characteristic colours disappear and to the fact that no known method of mounting will preserve these delicate colourings. Again I am indebted to Professor Symington for suggesting that these specimens should be drawn to scale and coloured immediately after removal from the abdomen. This course I have followed, and I think the illustrations show in conclusive fashion the morbid changes through which the obstructed appendix passes, and by comparing these with the history and clinical signs we are able to arrive at an accurate estimate of the intra-abdominal condition in any given case.

Stage I.—Coloured Illustration I. is from a coloured drawing of an appendix removed 21 hours after the onset of symptoms (Case 46). (See Coloured Illustrations inset.)

CASE 46.—A man, aged 45, a patient of Dr. W. McWilliam of Banbridge, took ill at 3 A.M. on Oct. 2nd, 1915, and was operated on about midnight. The attack began with very severe pain in the upper abdomen referred to region of umbilicus. Vomiting took place at short intervals throughout day. Pulse and temperature normal. Considerable rigidity in right rectus muscle and tenderness localised to small area immediately below McBurney's point. When I saw him temperature was 98° 6', pulse 84, tongue clean, and breath not foul. The pain was of a colicky character, and between the attacks he was quite comfortable. Small area of tenderness as above stated; otherwise abdomen normal. The diagnosis of obstructed appendix was made and appendicectomy performed. On opening abdomen no sign of inflammation; appendix tense and rigid; concretion felt close to proximal end. Appendix removed. Uninterrupted and rapid recovery.

This is a typical example of the first stage of obstruction of the appendix. There are no signs either local or general of inflammation. There are 10 such cases in the series and results of treatment by operation leave nothing to be desired. The period of disability is short and the risks of complications and sequelæ almost nil. And yet if left to nature or

if treated on medical lines a certain proportion of them will proceed in the direction of gangrene and perforation as exemplified in the succeeding stages.

Stage II.—In the following case operation was performed 24 hours after first symptom.

CASE 55.—Patient, a young woman aged 21, was seen by Dr. W. Martin of Whitehead, on the night of July 10th; history of having been ill with pains in stomach and vomiting for six hours. Temperature and pulse normal; no sign of any trouble in abdomen. He saw her again next day; temperature 100° and pulse 100; he sent her straight into hospital. At operation an appendix obstructed by a concretion at its base was found; very small area of gangrene on one side of organ. (Fig. 4.) Recovery in this case was retarded, as it frequently is in cases of gangrenous appendix, by infection of the layers of the abdominal wall, but the patient ultimately made a satisfactory recovery.

Here we have an appendix exactly similar to the first, but somewhat later in the course of the disease, and it seems reasonable to conclude that this is the second stage of the disease which follows obstruction.

The next case is that of a patient operated on 30 hours after the onset of symptoms. (Coloured Illustration II.)

CASE 58.—A woman aged 35, a patient of Mr. W. Boyd, of Banbridge, took ill at 9.30 P.M. on April 2nd, 1915, with pain in epigastric region and vomiting; symptoms lasted continuously for 12 hours. When Mr. Boyd saw her temperature and pulse were normal; no pain, tenderness, or rigidity in any part of abdomen. Four hours later pain had returned, not now in epigastric region, but in right iliac fossa. Temperature now 101° 2' and pulse 104. When I saw her about 12 hours later (that is 30 hours after onset) temperature was 101°, pulse 108; there was extreme tenderness not only over appendix, but over whole lower abdomen. Fig. 3 and Coloured Illustration II. are from drawings of the appendix which was removed. On opening the abdomen a huge, tense, obstructed appendix was found. During manipulations a concretion was felt to escape into the caecum, and when the appendix was afterwards distended with gelatin a cavity corresponding to this became evident. The appendix contained a number of small concretions and a large quantity of foul pus mixed with faecal matter. There were two considerable areas of gangrene. Recovery uneventful; patient left hospital in four weeks.

Here let me direct attention first of all to the absence of symptoms and signs when first seen by Mr. Boyd, and, secondly, to the moderate rise of temperature and pulse with the appearance of gangrene. This is the further stage in a disease caused by an obstruction.

The next case was operated on 31 hours after the onset of symptoms.

CASE 59.—Man, aged 35, a patient of Dr. G. F. Campbell, of Bangor, took ill on Dec. 21st, 1915, with severe pain over "lower end of breast-bone," and vomiting. Similar attack two years before. After 12 hours the pain began to settle in right side about 1 inch above McBurney's point. Thirty-one hours after onset tongue was clean, temperature 100° 4', pulse 80; abdomen showed a single tender spot; right rectus muscle somewhat rigid, but not markedly so. Operation immediately by gridiron incision. There were some adhesions, but without difficulty the appendix, completely gangrenous, was removed. (Fig. 5.) Stump of appendix could not be invaginated, but was simply ligatured in abdomen.

The appendix was a typically obstructed one in which the whole organ was obstructed, distended, and gangrenous. This man before being operated on declared that he was getting over the attack just as he had got over the previous one, and one could not from clinical signs have denied the possibility of this, and yet we find this foul gangrenous appendix with perforation imminent. It is difficult to decide why in the previously mentioned cases one or two areas of gangrene occur, whilst in this case the whole organ was affected.

Coloured Illustration II. is an example of an unperforated gangrenous appendix, of which there were 18 in the series. They all recovered, though they are somewhat less satisfactory than the foregoing, and mainly for two reasons: (1) a few of them required drainage owing to the suspicion of infection of the peritoneal fluid, and therefore ran the risk of hernia; (2) even in the absence of peritoneal infection there is considerable liability to infection of the abdominal wall, a fact previously pointed out by Mitchell and others. On the whole, prognosis is rarely grave in this series.

Stage III.—Coloured Illustration III. shows the condition of the appendix at a later period.

CASE 90.—Patient, a woman aged 47, seen with Dr. R. Boyd, of Strandtown on Oct. 12th, 1915, had already been ill three days. Examination showed a well-defined mass in the right iliac fossa and on right side of pelvis. Temperature 101° 5'; pulse 108. She was at once sent to hospital and operated upon. There was an abscess of considerable size situated in right iliac fossa and extending down into right side of pelvis. Appendix gangrenous and perforated; and about 1½ inches from base obstructed by large concretion; also concretion in abscess cavity.

This is unfortunately the usual type which one meets with at operation, but the previous history shows that it began with the same early symptoms of vomiting and pain in the upper abdomen; after 24 hours pain in the iliac fossa as

secondary inflammatory changes reach the peritoneal coat of the appendix; after 36 hours perforation ushers in suppurative peritonitis, and soon a large abscess extending into the pelvis has developed.

This is a type of the 59 obstructed, gangrenous, and perforated appendices occurring in Stage III. A consideration of their histories shows that most of them were seen during the second stage, and not a few of them even in the first stage. As a profession, therefore, we cannot absolve ourselves from responsibility for failing to recognise, or at all events to prevent, the dangerous course of the disease.

First, and most important, look at the death-rate—8 deaths out of 59 cases, 13.5 per cent. It may be urged by some that such a high mortality was due to immediate operation. In only one case can I think, on looking back, that I might have been justified in postponing operation (No. 102, a child aged 2½ years), though, on the other hand, there would certainly have been also the opposite possibility that the child would in 12 hours have been moribund. Of the other deaths two, Nos. 40 and 114, were due to rupture of a localised abscess into the general peritoneal cavity—a most fatal complication and one directly due to delay in operating.

prominent feature, and recurs from time to time as the patient tries to relieve his thirst. Constipation is usually a prominent feature. These are the symptoms of the first stage—as for signs, the temperature rarely exceeds 99°, the pulse may show a slight increase in frequency, though it is often normal, and between the attacks of pain the patient is comfortable. On examination of the abdomen some tenderness will be found when pressure is made over the distended appendix, but the rectus shows but little rigidity. Operation at this stage reveals an appendix tense, rigid, and distended, as exemplified by Coloured Illustration I.

Twenty-four hours later, if the obstruction persists, we shall find diminution of pain, with disappearance of vomiting. The temperature and pulse are now slightly elevated, the temperature being, say, 99° to 100° and the pulse 110. An examination of the abdomen shows not only an area of extreme tenderness near McBurney's point, but also a wide area of rigidity. Operation reveals an appendix partially or wholly gangrenous, surrounded by a varying amount of plastic lymph gluing it to the neighbouring organs. Sometimes the omentum will be found wrapped round the diseased organ and closing off the general peritoneal cavity, which contains an excess of fluid. If such were the circumstances surrounding every perforation the outlook would not be so gloomy, but often we find no omental seftny on

FIG. 3.—Longitudinal section of appendix obstructed by concretion and containing concretions.

FIG. 4.—Obstructed and gangrenous appendix.

FIG. 5.—Obstructed and completely gangrenous appendix.

Two died of pneumonia, which could not have been foreseen. One death was due to acute intestinal obstruction (No. 95), which had gone on well for a fortnight, the temperature and pulse having been normal for ten days. Three cases, Nos. 87, 97, and 106, all children, were moribund on admission to hospital—they had their abscesses opened under local anaesthesia, though they were past all but the remotest chance of recovery. What evidence is there here for further delay when at least five of the cases had already been delayed too long, viz., the three last mentioned and the two cases of ruptured abscess?

So much for the death-rate. Let us now look at the complications—secondary abscess, faecal fistula, hernia, pneumonia, &c.; of such the earlier cases are free. Then one must consider prolonged convalescence, the semi-invalidism, and the incapacity for work which follow these.

Typical Case of Obstruction of the Appendix.

Keeping in mind these stages, let us now endeavour to reconstruct a typical case of acute appendicular obstruction, from the onset of symptoms until perforative peritonitis occurs.

The disease begins with severe pain usually referred to the epigastric or umbilical region; it is colicky in character and is very severe, it is soon succeeded by vomiting which, though occasionally absent, is usually a

patrol, and when rupture occurs the line is broken and extensive invasion of the peritoneum takes place. Figs. 4 and 5 and Coloured Illustration II. are examples of this stage.

When rupture of the gangrenous appendix and infection of the peritoneal fluid have occurred we shall find a further attack of pain, this time referred to the right iliac fossa, continuous in character and often more severe even than the pain in the original obstruction. Vomiting is not a marked feature of this stage, though a feeling of sickness or slight vomiting may occur. Constipation is still present. At the moment of perforation the temperature may fall to sub-normal, but soon begins to rise again, except in very grave cases, and the pulse is greatly accelerated, running up to perhaps 120, or even more. Examination of the abdomen reveals a board-like rigidity of the muscles over the whole of the right side of the abdomen; the point of maximum tenderness will depend upon the situation of the ruptured appendix. Operation will show either a localised collection of pus or a general peritonitis dependent on whether the material from the appendix has been limited or not. Coloured Illustration III. is an example of an appendix from such a case.

These outlines may be regarded as the ordinary signs and symptoms of a case of obstructed appendix, but certain exceptions must not be lost sight of.

For example, in the case of an appendix which is lying in the pelvis it is not unusual to find both signs and symptoms referred even from the first to the pelvic region, or even to find a gangrenous appendix in the pelvis without definite

symptoms suggestive of an appendix disease at all. In such cases we have to depend on the history of an acute onset, painful micturition, and localised tenderness and swelling on vaginal or rectal examination.

A retrocaecal appendix becoming obstructed produces at first the typical symptoms of pain and vomiting referred to the upper abdomen, but afterwards the pain and tenderness are referred to the flank, or even to the site of renal pain beneath the last rib.

Where the appendix is adherent to the anterior abdominal wall tenderness and rigidity are more marked than when the anterior parietal peritoneum is unaffected.

Is pain ever absent in these cases? Probably it is never absent throughout the attack, but pain and discomfort frequently disappear when gangrene is developing and when rupture is becoming imminent. Comparable to this phenomenon is the disappearance of pain in a strangulated hernia when the gut is becoming gangrenous. Vomiting is a characteristic feature of the early stage of obstruction of the appendix. It is not so severe as in intestinal obstruction, is never faecal, and after the stomach has been emptied is only provoked by the taking of something to relieve thirst. In the late stages of peritonitis, however, the vomiting may be continuous and not infrequently gives place to hiccup.

It will thus be seen that perforation of the appendix in the great majority of cases is preceded by well-defined signs and symptoms, extending usually to a period of not less than 36 hours, and of so definite a character that there should be no excuse for allowing a case to proceed to perforation if it be seen during this preliminary period. There may be some doubt as to the right course to pursue in cases which have already reached Stage III., but in regard to the earlier stages there can be no question that such cases should be operated on without delay, and where the history and the signs lead one to suppose that perforation is near at hand then no delay or disturbance of the patient should be permitted until after the appendix has been removed. In this type of case the presence of pus, far from justifying operation, must be taken as incriminating some one responsible for the care of the patient.

Prognosis.

Within recent years discussion has been rife on the mortality following acute disease of the appendix, and without doubt the figures are showing improvement. Lett compares two series of a thousand cases each from the London Hospital: in 1900-1904 and in 1912, with death-rates of 17.2 and 3.2 per cent. respectively—a reduction of 14 per cent. These results take no cognisance of (1) cases moribund on admission and (2) cases too ill to be moved to hospital—a not inconsiderable number, especially in children. In 1910 Mutch analysed the results of the treatment not necessarily operative, of 545 cases at Guy's Hospital. These gave a mortality of 13 per cent. But here again if we wish to get at the general mortality rate we must allow for those cases which died before removal to hospital was thought of or at all events effected. More recent results will be better, but still it must be admitted that appendicitis (using the term in its generally accepted meaning) is a very lethal disease.

How can this appalling death-roll be reduced? This leads me to ask the further question—What is the direct cause of death in this disease? To this the answer is suppuration. The truth of this has been proved repeatedly. A. B. Mitchell in 1910 analysed the results of 500 consecutive operations for appendicitis at the Royal Victoria Hospital, Belfast; although the total mortality ran up to 15 per cent. yet no single death occurred in a non-suppurative case. In 1910 Anderson reported the results of 973 operations at the Nottingham General Hospital; out of 89 deaths, only 1 occurred in the absence of pus. Burgess out of 500 consecutive operations at the Manchester Royal Infirmary in 1912 found but one death where the inflammation was limited to the appendix. In the series here under review no death followed operation in a clean case. Amongst cases already suppurating I find the following figures (in some cases approximate):—

| Operator. | Sup. cases. | Deaths. | Operator. | Sup. cases. | Deaths. |
|----------------|----------------|------------|----------------|----------------|------------|
| † Beaton ... | 73 ... | 9 (12.3%) | Paterson ... | 56 ... | 5 (8.9%) |
| Billington ... | 360 ... | 48 (13.3%) | Richardson ... | 350 ... | 48 (13.7%) |
| Burgess ... | 365 ... | 39 (10.6%) | Irwin ... | 84 ... | 10 (11.9%) |

* Suppurative.

† Assumes deaths to have been amongst suppurative cases.

Under modern methods, therefore, whilst the mortality in clean cases is practically negligible, and whilst the results in suppurative cases will vary with the dexterity, technique, and sometimes the rapidity of the operator, as well as the subsequent care bestowed on the nursing of the patient, widespread and general improvement can only be attained by intelligent recognition on the part of the practitioner of those cases which are likely to go on to pus formation.

If, then, pus be the cause of death, the cause of pus is perforation of the appendix. In the present series perforation was present in 50 per cent. of the cases. Perforation cannot, I fear, be anticipated in every case. In two cases of the series, Nos. 2-3, it was the perforation which directly caused the symptoms for which the medical man was consulted, and speaking generally we shall meet from time to time cases in whom inflammatory changes have been going on without the knowledge of the patient. Such perforations, though of small size, are most sudden in onset. They compel attention and demand immediate surgical interference, and hence their death-rate is low. Not so the perforation of acute appendicular obstruction, which, after causing considerable pain at first, enters upon a semi-quiet stage only to perforate later. The perforation is extensive and ragged, the material extravasated is foul, virulently infective, and considerable in amount.

Investigation of the cases shows that no less than 28 of them required, or were thought by the practitioner to require, operation on the third day. These appeared to be progressing favourably until about 36 hours after the onset, when they seemed to get suddenly worse. There can be no doubt that this was due to perforation. The problem, therefore, is, How shall we best anticipate this grave complication? Not by blindly waiting and trusting to the fact that many cases recover without operation, but by teaching our students and practitioners the morbid anatomy of the obstructed gangrenous appendix, that it may be recognised by its history and its physical signs and symptoms, that it is never "a mild attack of appendicitis," but a grave and potentially fatal disease, demanding promptitude and careful handling if the patient's life is not to be placed in jeopardy.

GIFT TO THE NORTHAMPTON GENERAL HOSPITAL.—Mr. G. T. Hawkins, of Northampton, has given £3000 towards the building and equipment of a pathological laboratory for Northampton General Hospital. It is hoped that the work of construction will commence almost immediately.

ROYAL SANITARY INSTITUTE.—Courses of lectures and demonstrations for the spring term, 1919, at the Royal Sanitary Institute, 90, Buckingham Palace-road, London, S.W., commence next month. A course for sanitary officers will be given on Mondays, Wednesdays, and Fridays, from Feb. 17th to May 2nd, the fee for the first part, which will deal with sanitation generally, being £2 12s. 6d., and for the second part, which will deal with food inspection, £1 1s. The complete course is £3. On Mondays, Wednesdays, Fridays, and Saturdays (not consecutive) from Feb. 21st to May 2nd there will be a course of lectures for women health visitors, tuberculosis visitors, school nurses, and school teachers, a supplementary course for child-welfare workers beginning on Feb. 24th. The fee is £1 11s. 6d. in both cases, but the two courses may be taken together at an inclusive fee of £2 12s. 6d., 10s. 6d. of this being carried towards the examination fee. The lecture hour in each case is 6 P.M.

THE CONTROL OF THE UPPER FRAGMENT

IN HIGH FRACTURES OF FEMUR AND HUMERUS BY
A NEW FORM OF PELVIC-FEMUR SPLINT AND
ARM SPLINT.¹BY JOHN ROBERT LEE, M.D., B.S. MELB.,
F.R.C.S. EDIN.,MAJOR, R.A.M.C.; OFFICER IN CHARGE, SURGICAL DIVISION, FULHAM
MILITARY HOSPITAL, HAMMERSMITH, LONDON, W.

At Fulham Military Hospital, London, we have had many opportunities of treating fractured femurs and also of seeing the results of treatment in other hospitals, as shown by cases which have been transferred to us. The number of cases which come to amputation from sepsis or which join up in bad position with stiff joints is very great. For instance, during last June we had 20 fractured femurs sent over to us from France, where they had been in special hospitals from one to five months; of these, some were in fairly good position and not very septic, several of them were more or less united in bad position, and most of them had sequestra due to trauma and inefficient drainage. It is the fractures of the femur in its middle third that I wish especially to deal with. Ten of the 20 femur cases admitted in June were those of fractures in the upper

FIG. A.—Pelvic-femur splint.

FIG. B.—Arm splint.

third; of these, 3 were in good position and only slightly septic, 2 were in fairly good position but septic, 5 were in bad position, and of these 3 were very septic. Therefore, 50 per cent. were in bad position and 50 per cent. were very septic. These results should be capable of improvement.

Fractures of upper third of femur.—The position or displacement of the fragments in fractures of the upper third of the femur, as a rule, is as follows: (1) The upper fragment is abducted and flexed by the glutei and ilio-psoas muscles; (2) the lower fragment is displaced backwards, upwards,

and inwards by the hamstrings, quadriceps and adductor muscles. The powerful adductor magnus being an exceedingly important factor, there is also some rotation. This deformity is typical; the main causes producing it are the direction of the fracturing force and the action of the muscle groups.

The essentials of correct treatment rest on an adequate consideration of the anatomical factors and the principles of

FIG. C.—Radiograms of fracture (compound) of right femur at upper third, with abduction of upper fragment. After application of pelvic-femur splint adduction and fixation of upper fragment with good alignment are seen to result.

surgery, the latter including arrest of hæmorrhage, establishment of efficient drainage, provision for antisepsis, general care of the patient, massage, &c.; I want, however, to draw special attention to the anatomical factors. The fragments should be brought into correct alignment, the muscle groups placed in a condition of physiological rest, and the limb securely fixed in order that there may be no movement of the fragments or spasm of muscles; at the same time any interference with the circulation of the limb should be avoided.

Hitherto it has been taught that in fractures of the upper third "the upper fragment, being short, cannot be controlled." Therefore attempts have been made to procure alignment by abducting the lower fragment. *This method is wrong in principle.* I have taken measurements of a great many men and find that the distance between the symphysis pubis and the adductor tubercle is on an average two inches greater in the abducted position than when the knees are side by side. Hence in the abducted position of the fractured limb the adductor group of muscles have a greatly increased pull and are in a condition of spasm instead of physiological rest. Therefore, although the two fragments are brought parallel to one another, an X ray examination in many cases reveals the fact that the upper end of the lower fragment has now moved upwards a distance of about two inches and takes up a position near the lesser trochanter. An amount of extension that can be applied with safety fails to correct the shortening. Unless the two ends of the bone were impacted what has been accomplished is increased overlapping of the fragments and not an elongation of the adductor muscles. It occurred to me that if the upper fragment could be controlled and the abduction overcome the fragments could be brought into proper alignment with the limb and the muscles in a nearly normal position.

Pelvic-femur splint.—With the above principles in view I designed a new appliance which I have called a pelvic-femur splint.

It consists of a grip with two pads (Fig. A, 1) which fit the pelvis; modified Thomas' frames for both lower extremities are hinged on to the pelvic grip (2). The pelvic grip can be adjusted to fit any pelvis comfortably and securely. The pelvis and upper part of the femur on each side are grasped by the pelvic pads. The abducted upper fragment can be controlled and adducted to its normal position quite easily. (See radiograms, Fig. C.) The amount of pressure required is regulated and the fragment kept in position by a fly nut

¹ Being part of a paper read at the Section of Surgery of the Royal Society of Medicine on Dec. 4th, 1918.

working on a screw (Fig. A, 3). Both limbs can be put up in the iron frames in the ordinary way. The upper fragment having been brought into proper position, the lower one can be placed in correct alignment by abducting or adducting, raising or lowering as required while on the splint, the latter working on hinges or joints (near 2, Fig. A). Any backward displacement can be corrected by manipulating the small wooden splint by means of screws (Fig. A, 4). Adequate extension can be applied. If much extension is found to be necessary an adjustable piece similar to that used in the arm splint (Fig. B) can be fitted from the pelvic pad to the axilla on each side; hence the upward thrust of the extending force will be partly taken by the axillæ and trunk and the pelvic calliper grip not displaced.

All these manipulations should be done on an X ray couch (if necessary under an anæsthetic) so as to see that the ends of the bone are in actual alignment, not merely supposed to be so. Having completed all manipulations necessary the binding screws are firmly adjusted. The pelvis and lower limbs can be suspended by means of pulleys on a frame—the patient's body raised as needed for convenience of nursing, the prevention of bedsores, &c. Many patients complain that splints fitted with a ring around the thigh as in a Thomas' splint, cause much discomfort. With this splint there are no bands encircling the limb; hence, no interference with the circulation occurs, which is a very important factor, especially in septic cases.

The splint can be easily applied with a minimum of movement. When it is applied the fragments of the bone are securely held in proper anatomical position; the muscles are at rest. All necessary dressings, nursing, &c., can be carried out, and if any movement of the patient is necessary he is moved as a whole and not in parts.

FIG. D.—G.S.W. of right arm, compound fracture, displacement, upper fragment abducted. After application of arm splint the fragments are shown in good alignment.

The iron leg portion of the splint can be raised at right angles to the operating table, and thus out of the way should any operative procedure be necessary, the upper fragment being perfectly controlled by the grip pad, the lower steadied by an assistant.

The splint is made double to ensure steadiness and to enable the patient to be moved easily. The final result is that the patient lies with the fractured thigh in its proper position comfortably beside the healthy limb. In all cases skiagrams are necessary—both antero-posterior and lateral—in order to show whether the fragments are actually in correct position.

The splint is useful in all fractures below the great trochanter where there is abduction of the upper fragment,

but its use is not limited to compound fractures of the femur. It would be of great value in treating fractured pelvis, intracapsular fractures, and anterior poliomyelitis to give rest to paralysed muscles.

Arm splint.—An efficient splint for the upper extremity should be firmly fixed to the patient's body so as to carry the limb and keep the fracture in proper position and at rest. Usually the splint hangs on the limb instead of supporting it.

The splint for the upper extremity which has been designed by me consists of two parts (Fig. B). One fits firmly on to the trunk (1); the other carries the limb (2). The upright trunk part is fitted to the hip with an adjustable piece which allows its upper forked end to be securely fitted into the axilla (3). This part is fastened round the body by two straps. To the upper end of the fork the part which carries the limb is attached by joints (4), which allows the arm to be abducted to any desired angle and retained there. The centre of movement passes through the head of the humerus. By releasing a set screw (5) on the tubular piece the hip portion can be turned round; the limb attachment is then turned completely over; hence the splint can be used for right or left limb equally effectively. The splint can be adjusted so as to support the shoulder in any desired position. The forearm can be placed in either the semi-prone or supine position. Provision is made for any necessary extension. When properly fitted the patient carries the upper extremity with the whole weight supported by the body; hence the limb is kept quite steady and at rest. Dressing of wounds, massage, &c., can be carried out without interfering with the splint. (See radiograms, Fig. D.)

After much careful observation of many cases I have designed these two splints, one for each extremity, and have proved that both appliances are efficient, easy to apply, and give great comfort to the patient. I hope that their use in treatment of such cases may help to produce better results in the future. In conclusion, I desire to express my warmest thanks to my colleagues, especially to Lieutenant-Colonel C. T. Parsons, for valuable help and encouragement; to Dr. Florence Stoney for her great assistance with the X rays; to the staff of the Kensington War Hospital Supply Depot; and to Messrs. Arnold and Sons, who made the splints for me.

MENINGOCOCCUS BRONCHO-PNEUMONIA IN INFLUENZA.

BY WILLIAM FLETCHER, M.D. CANTAB.,

CAPTAIN, R.A.M.C.

(From the Laboratory of the University War Hospital, Southampton.)

THE epidemic of influenza which has visited this country during the later months of the year 1918 has been characterised by an unexampled severity due to pulmonary complications. In the cases of broncho-pneumonia, which have been responsible for most of the deaths in this epidemic, the lungs are invaded not by Pfeiffer's bacillus alone, but by that bacillus aided and abetted by one or other of the many organisms which inhabit the respiratory tract, such as pneumococci, streptococci, diphtheria bacilli, and, in the cases which I am about to describe, meningococci.

Sometimes these secondary organisms are, by themselves, of low virulence; the pneumococci are very often of the fourth group, and the streptococci frequently belong to the *viridans* type, but when they join forces with the influenza bacillus and follow its lead in a descent upon the lungs they can play a deadly part.

Bacteriological Findings.

Between Sept. 25th and Nov. 23rd, 1918, cultures were made, after death, from the lungs and from the heart's blood of 36 American soldiers who had died from broncho-pneumonia. These men, for the most part, had been taken ill with symptoms of influenza a week or 10 days before admission to this hospital, while they were on board transports crossing the Atlantic.

In films prepared from the lungs of some of them the only organisms to be seen were Gram-negative diplococci in enormous numbers, the majority of them lying within polynuclear cells. In one or two instances they were so numerous that there was hardly a cell that did not contain some. Plate cultures were made post mortem from the lungs of all the cases; numerous colonies of Gram-negative cocci were obtained in 11 of the 36, and in three instances

they were grown from the heart's blood as well. Subcultures of these cocci from seven of the cases were examined at the Central C.S. Fever Laboratory, with the result that six were found to be Type II. meningococci, while the seventh conformed to Type I. The other four strains were, unfortunately, not kept for further examination, but as, with one exception, they were derived from cases of influenza which occurred on the same transport as the other seven, and as the appearance of the films prepared from the lungs was the same, it is probable that they, too, were meningococci.

In all these 11 cases Pfeiffer's bacillus was present in association with the meningococcus; it was not always found in the films, but it always grew on plate cultures made from the lungs. In two instances pneumococci were also present; in one case streptococci and in another both pneumococci and streptococci were found.

Clinical Features: Condition of Lungs Post Mortem.

The duration of illness from the beginning of the influenza to the end in death was from 11 to 16 days, except in one instance, where the patient lived for 24 days from the date of onset. The men did not reach this hospital until they had been ill for some time, and there are no available clinical records of the course of the disease in its early part. All of them, except one who came from a hospital in France, had been attacked by influenza while on board the transport, and when they were admitted here about a week later they were very ill indeed. Four of them died within 48 hours of admission, 4 within a week, and 3 within a fortnight.

There were no special features by which these meningococcus broncho-pneumonias could be distinguished clinically from the other cases in this ship epidemic which were due to a combined infection with Pfeiffer's bacillus and pneumococci or streptococci, except that in the meningococcus infection there was possibly a greater tendency to hæmoptysis. In one or two of the cases which were seen in the earlier stages the sputum was rusty and tenacious, but for the most part it was nummular, airless pus mixed with dark blood.

In several of the cases an even high temperature was gradually coming down by lysis during the first few days after admission, when it suddenly rose again as though some fresh bacterial invasion had occurred, and instead of remaining steady there were wide oscillations between 99° F. in the morning and 104° or 105° at night. The pulse-rate in these fatal cases increased to 120 or more, and the respirations to about 60. It is noteworthy that in the case of one man, from whose heart and lungs meningococci of Type II. were isolated, the skin was a bright yellow colour for several days before he died. None of the patients showed any signs of meningitis before death took place, nor was any evidence of it seen afterwards.

In every case confluent broncho-pneumonia was found post mortem, producing large areas of consolidation, and both lungs were affected, though generally the process was more advanced on one side than on the other. In two instances red hæmorrhagic patches beneath the pleura were a striking feature, in four the pleura was covered with recent lymph, and in two there was turbid fluid in the pleural cavity.

In some cases the broncho-pneumonic patches coalesced to such an extent that whole lobes were solid and airless, while in others the patches of consolidation remained separate, so that the affected lung felt like a bag of plums. In every case when pressure was applied by squeezing the lung, thick yellow pus oozed from the blocked bronchioles. In one instance there was an abscess with ragged walls at the base of the right lung, which contained a thick, dark, red fluid full of Gram-negative cocci.

Other Observations.

Shortly after the death of these men a British soldier suffering from bronchitis was admitted from France, where he had been under treatment in an American hospital. He had been taken ill suddenly with giddiness and pains in the back 15 days before. His temperature was of the same type as that of the American soldiers who died from meningococcus broncho-pneumonia, swinging from 98° or 99° in the morning to 103° at night, but his pulse was not above 100 and his respirations were never more than 40 to the minute. Films prepared from his sputum, which was frothy and purulent, contained large numbers of Gram-negative cocci, and a plate inoculated with it gave a profuse growth of meningococci of Type IV. and a few staphylococci. This patient's temperature came down by lysis and was normal on the twenty-fifth day.

Lieutenant-Colonel M. H. Gordon, to whom I am greatly indebted for carrying out the agglutination tests on these meningococci, has very kindly drawn my attention to a paper by Jacobitz,¹ who investigated an outbreak of disease which occurred in a Jäger battalion at Colmar during February, 1906. He found two men suffering from typical cerebro-spinal meningitis without complications, three cases of meningitis associated with meningococcus pneumonia, and one case in which there was meningococcus pneumonia without symptoms of meningitis; this last case ended by crisis and recovery. In addition, he observed four cases of bronchial catarrh (with meningococci in the sputum) without any symptoms of meningitis, all of whom recovered. He does not appear to have found Pfeiffer's bacillus in any of his patients.

Summary.

1. In the post-mortem examination of 36 men who had died from broncho-pneumonia following influenza, Gram-negative cocci were the predominant organisms found in the lungs of 11 cases.

2. All the men, with one exception, had been taken ill on board the same transport.

3. In six cases these Gram-negative cocci were Type II. meningococci and in one case they belonged to Type I. In four instances the cocci were not tested by agglutination.

4. In each of the 11 cases Pfeiffer's bacillus was found in symbiosis with the Gram-negative cocci.

5. The meningococcus, like other "respiratory" organisms, may, when it occurs in conjunction with Pfeiffer's bacillus, produce a fatal broncho-pneumonia.

APPARENT IMMUNITY FROM INFLUENZA AT A PUBLIC SCHOOL.

By G. E. FRIEND, M.R.C.S., L.R.C.P.,

MEDICAL OFFICER, CHRIST'S HOSPITAL SCHOOL, WEST HORSHAM.

IN view of the fact that certain statements have appeared in the public press in reference to the absence of cases of influenza among the 800 odd boys at Christ's Hospital School, West Horsham—which statements were not entirely accurate—it is possible that some authentic account of the local conditions may be of interest.

Incidence in Summer and Winter Terms.

The summer term, which had shown a good health return, ended on July 25th. On Saturday, July 20th, the school cricket XI. went to Brighton to play a match. As a sequel to this visit five of the team became infected with influenza and were admitted to the school infirmary on Sunday morning with 3 other boys who were not in the team but came from the same houses as those who were, and had obviously been infected from them. Only 2 cases were admitted on July 22nd, and 7 on Tuesday, 23rd, 18 on Wednesday, 24th, and 4 cases on the morning of the 25th. There were thus 39 cases occurring as a result of this exposure. Nearly all these boys were from the same houses as the first five. There were during the previous ten days 21 cases of mild influenza occurring in various houses of the 16 that comprise the school, but they were sporadic and milder in type than the 39 later cases. None of these 60 cases were severe, and there was no case with any complication in the school.

Several cases (probably about 30) occurred after the boys arrived home among those who must have been ill on the morning of leaving but who did not report. Every term all the boys are inspected by me on the afternoon of the day before going home, but as they start at 6 A.M. in the morning it is impossible to inspect them nearer the time of departure.

During the holidays the infirmary was washed down and the mattresses and wards used for influenza cases were disinfected. I did not, however, think it necessary to carry out disinfection on a larger scale.

The winter term began on Sept. 13th and ended on Dec. 18th. During the whole term the medical illness was less than it had been in any term since 1898. The total number of medical cases admitted was 115 for 13 weeks. Of these, 36 were "chills"—i.e., cases of illness with raised

¹ Der Diplococcus Meningitidis Cerebrospinalis als Erreger von Erkrankungen der Lunge und Bronchien, Jacobitz, Zeit. f. Hyg., 1907, lvi.

temperatures of 24 hours or more without definite physical signs. The cases occurred sporadically among the 16 houses, and there was nothing in their distribution or incidence to suggest that they were anything more than the ordinary so-called "chill."

Preventive Measures.

After the experience of the summer term case was naturally anxious, and at the beginning of the winter term I advised the Headmaster to stop all leave of absence and to keep the boys strictly in bounds. The school is self-contained and lies in a ring fence. Walks outside were allowed, but the town, $2\frac{1}{2}$ miles away, and all the houses off the school estate were put out of bounds. It was not found possible to keep visitors away, and swarms of these arrived every Wednesday and Saturday throughout the term, many usually staying over the week-end, nor was it possible to stop all leave of absence. There was a further exposure to infection via non-resident masters and servants, the latter especially being possible carriers. These are supposed to report to me in the event of any illness occurring in their homes, and when possible I suspend them coming into contact with the school, but I do not think this is a very certain check. As an attempt to adjust actual conditions to the reduced diet values which have recently pertained we had previously increased the amount of sleep by one hour and decreased the amount of work and play, and these measures were continued in force. I also introduced the nasal drill as described by Dr. Isabel Ormiston in THE LANCET of August 24th, 1918. The method used is substantially as described by her, and the boys do the drill twice daily—on rising in the morning and before going to bed at night. The nose-blowing is performed six times to the word of command, which is given by the monitors, who act as pupil instructors of physical training, and form the first exercise at every P.T. drill, which at present is done in the dormitories after washing in the morning. (I am aware that this is not the most suitable time, but at present it has not been found possible to give another time for P.T., and it is not done on an empty stomach, as the boys are given two wheaten biscuits each on rising.)

Dr. K. L. Hunt, bacteriologist to St. George's Hospital, suggested to me the possibility of vaccine prophylaxis—and after talking it over with him we decided to give a single small dose of polyvalent influenza vaccine. We were averse to using a mixed vaccine, because we regard cases of pneumonia and streptococcal infections as "complications" occurring, in the majority of cases, after the onset of an influenza infection. In some cases, it is true, pneumonia is present when one first sees the case, but that is, we think, to be expected in a certain percentage of cases. Also, as the inoculation of a large school might, if not successful, have occasioned considerable comment, I preferred what seemed to me the lesser risk of an unmixed vaccine. We decided to give a 70 million dose to all boys over 14 and 30 million to those under 14. A post-card was sent to every boy's parent or guardian informing them that their boy would be inoculated as a preventive measure unless they wrote to me that they objected.

Account of the Prophylactic Vaccination.

I inoculated the boys on Oct. 30th (approximately at half term).

306 boys received 70 million. | 327 boys received 30 million.

Total: 633 boys inoculated.

39 boys' parents objected to inoculation.

128 boys I considered unsuitable for inoculation.

19 boys were absent ill.

Total: 186 boys not inoculated.

Approximately 77 per cent. of the school were inoculated. In addition 34 of the staff received 70 million.

The proceeding was, of course, voluntary as regards the staff and their families, but the response to the invitation was poor, as approximately 13 per cent. only of the staff and families were inoculated. Every precaution was taken. Temperatures were taken morning and evening the day before, the day of, and three days following, the inoculation. All games and O.T.C. parades were stopped for the same period, and only very moderate exercise allowed until the sixth day after.

All the boys were inoculated the same day by me, with the assistance of two nurses, one charting particulars, the other preparing the skin. The injection was made with a 5 c.cm.

Record syringe, holding 10 $\frac{1}{2}$ c.cm. doses, and given in the left forearm on the extensor surface just below the elbow. The first 100 were swabbed with ether, but after that, owing to the fumes, tinct. iodi was used.

The boys marched to the infirmary by houses, according to a time table previously circulated, stripped coats in my outpatient room, and then came through an inner room where the injection was given. Then returned to the first room and waited until the whole 50 boys in the house had been inoculated or rejected. In this way any bleeding, faintness, &c., was known of and seen to.

The needle used was dipped into boiling water between each puncture, and the syringe refilled every 10 punctures. The vaccine was made for me by Dr. Hunt from a series of cultures of Pfeiffer's bacillus obtained at St. George's Hospital in the year's epidemics, and was put up in bottles of 100 doses, the dose in each case being $\frac{1}{2}$ c.cm. of vaccine, the labels for the bottles containing the 70 and 30 million doses being different. In this way I was able to get through the whole 633 inoculations and see also the 167 rejected. Every boy was seen and questioned by me as to fitness before inoculation. Each house of 50 boys came up in charge of the head boy, who brought a list showing the temperature of the boys for that morning and the previous evening.

The temperatures were taken in each house by the house matrons, assisted by the masters or senior boys, and this work was supervised during the day by a nurse who was specially employed for this purpose and who afterwards charted the complete records. Possibly as a result of these precautions there were no cases of severe reaction.

The boys were all seen again three days after the inoculation (when they attended for the mid-term weighing) and were questioned by the nurse in my presence as to reaction with the following result:—

| Dose in millions | Local. | | Focal. | | General. | | Inoculated. |
|------------------------|--------|---------|--------------|-------|----------|------------------|-------------|
| | Marked | Slight. | Sore throat. | Cold. | Malaise | Diarrhoea. | |
| 70 | 0 | 4 | 10 | 1 | 19 | 0 | 306 |
| 30 | 0 | 6 | 9 | 4 | 29 | 1 | 327 |
| Total... | 0 | 10 | 19 | 5 | 48 | 1 (G. total, 83) | 633 |

In no case was a rise in temperature recorded. Of the 83 only one boy was sufficiently incommode to report at the infirmary, and he was one who had light brawny swelling round the site of puncture, which subsided after the application of a couple of cold-water compresses. Of the 48 cases of malaise probably half can be discounted, if not more, as no one had reported, and the majority of the histories were given in response to leading questions by the nurse. If all are included the number of reactions equal 13 per cent.

The Immunity from Disease in the Winter Term.

There were during the term no cases of definite influenza among the boys except one—a boy who had been inoculated with a 30-million dose on Oct. 30th. He went home to attend his mother's funeral on Nov. 20th, she having died from influenza. On his return on Nov. 24th he reported to me according to the school rule, and I kept him isolated. The same evening he had a slight rise of temperature, with headache and pain in the back; the next day coryza and cough—no other signs—and the temperature became normal in three days. Probably this was mild influenza. In regard to the rest, there were during the term 36 cases of "chill," as already mentioned. These were cases of raised temperature, malaise, slight sore-throat, &c., without definite physical signs admitting of an exact diagnosis. They all recovered with a day or two in bed on a light diet.

Influenza was from September on very prevalent in Horsham and in all the surrounding villages, and from Oct. 14th onwards there were cases among the staff living in the school precincts. On Oct. 14th a maid from the Preparation School House went down with influenza, and on the 15th and 18th a second and third went down. Two of these developed pneumonia the second day of disease. A fourth maid from the same house went home on the 19th quite well and went down with influenza at home that afternoon. She afterwards developed pneumonia. On the 23rd and 26th two maids in another house developed mild influenza. All these cases were immediately isolated in the infirmary, and there was no further spread in the school. On Oct. 24th a

master's wife and on Nov. 4th a second master's wife, living at the opposite end of the avenue, developed definite influenza. They were both isolated, and no further spread occurred. About 10 other cases occurred in various houses on the estate, but not so immediately in contact with the school proper. All these cases recovered, and except the 3 pneumonias there were no complications. None of these were inoculated, and of these cases 6 only occurred after the school had been inoculated.

As already stated, the total number of medical cases treated in the school during the term was considerably lower than the number for any other term, winter or summer, since 1898, before which date the records have not been tabulated. The majority of these were definite cases of bronchitis, pleurisy, gastritis, &c., but 36 were perforce classified as "chill." It may be argued that these were cases of modified influenza. Unfortunately, bacteriological examination was not practicable.

Against the diagnosis of influenza are the absence of definite symptoms, the short duration of illness in the majority of cases (the average time in hospital of the 36 is just under three days), and the complete absence of after-effects. In favour of the diagnosis is the known contact with many potential carriers and close proximity to several definite cases. Twelve of the 36 occurred before Oct. 30th, and 24 occurred after Oct. 30th. Of the 24 occurring after Oct. 30th, 7 were among the uninoculated = 4.2 per cent., and 17 were among the inoculated = 2.6 per cent. (2 with 70, 15 with 30 million).

The view has been put forward that the administration of any vaccine produces an increase of resistance to any organisms in the individual. 77.2 per cent. of the school were inoculated on Oct. 30th. Sixty-four medical cases of all kinds were admitted to the infirmary after that date; of these, 41 had been inoculated = 6 per cent.; 23 were uninoculated = 13 per cent.

The statement was made in the Press that I had instituted a routine nasal douche of potassium permanganate. This is incorrect. It would have been impossible to arrange to douche 800 noses by trained help, and I should regard such a proceeding, if left to the unaided resources of the boys, as a most unsafe method. I think the fact that inoculation was performed acted as a great mental factor. It is possible that the cases labelled chills were in fact cases of modified influenza, though, in my opinion, the clinical evidence is against this.

The chief factors in what is an extraordinary immunity appear to be—(a) the physical training, which though it has been seriously undertaken for six months only, has already produced a marked improvement in physique. (b) The nasal drill, which perhaps is the most important of all. (c) The fact that for the past three months the caloric value of the school diet has reached practically the pre-war value of 3000 calories per boy per diem—for the first time since 1916. (d) The effect of inoculation, therapeutic and moral.

It will be interesting to know when the school reassembles how many boys have contracted influenza, or have been definitely exposed to it during the holidays.

Note by Dr. E. L. HUNT.

The following note as to particulars of the preparation of the vaccine has been kindly added by Dr. Hunt.

The vaccine used was a polyvalent one, containing only the influenza bacillus, obtained from different sources.

The organisms used were as follows:—

- | | | | |
|-----|-----------------------|---------------------|--------------------|
| (a) | <i>Bac. influenza</i> | obtained from nose, | October, 1918. |
| (b) | " | " | sputum, June, " |
| (c) | " | " | nose, October, " |
| (d) | " | " | sputum, July, " |
| (e) | " | " | " September, 1918. |

These organisms from when first isolated had been kept going on blood-agar medium at 37° C.

The medium used for the vaccine tubes was rabbit's blood agar, made by adding some 5 drops of the blood, freshly obtained under aseptic conditions, to 4 c.cm. of melted lemco-peptone-salt-agar at about 60° C., the tubes being mixed, slanted, and allowed to cool.

Ten tubes were inoculated (Oct. 26th, 1918) from each of the 5 organisms, respectively (50 tubes) and grown for 48 hours at 37° C.

The vaccine was heated in a water-bath at 55° C. for 30 minutes. Sufficient vaccine was thus obtained to yield—

5 × 50 c.cm. bottles, $\frac{1}{2}$ c.cm. = 70 million;
5 × 50 c.cm. " $\frac{1}{4}$ c.cm. = 30 "

Clinical Notes : MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF PERICARDIOTOMY.

By T. P. NOBLE, M.D. EDIN.,

CAPTAIN, R.A.M.C.;

AND

A. B. VINE, M.R.C.S., L.R.C.P. LOND.,

CAPTAIN, R.A.M.C.

IN the following case pericardiotomy was performed on the twelfth day after passage of a rifle bullet through the chest, with recovery of the patient.

The patient, a lieutenant in the Lancashire Fusiliers, was wounded on April 11th, 1918, by a rifle bullet which entered in the third interspace $\frac{1}{2}$ in. internal to the nipple line on the left side, and had its exit $1\frac{1}{2}$ in. to the left of the mid-line behind, on a level with the seventh dorsal spine. His first sensation when he was hit was a burning pain behind; then he fell, and all power seemed to leave him. A few minutes later he was able to run 50 yards with the aid of a man supporting him on either side. He did not lose consciousness, but had considerable dyspnoea. Admitted to No. — C.C.S. (April 11th). The notes on his field medical card show the following: "Entrance and exit wound left chest, swelling in the left pectoral region, and signs of a small hæmothorax."

Admitted to No. — Stationary Hospital on April 14th. Considerable difficulty in breathing, and had to sit almost upright. P. 90, R. 30, T. 100.6° F. E. and E. wound as noted. (See Figure.)

The entrance wound was merely a puncture with a rather larger exit one. Cardiac dullness: Right side, 1 in. to right of sternum; left side, to the nipple line and upwards to the lower edge of the second rib. Pericardial friction heard to the right of the sternum and near the apex. Posteriorly there was dullness up to the level of the exit wound, breath sounds heard all over, but weak. April 16th: T. varies from 100° to 102°. Friction more marked and audible all over the præcordia. Dyspnoea continues and cough troublesome. April 20th: Cardiac dullness slightly increased, friction persists, dyspnoea more marked, cough very distressing. P. 92, T. 102.6°. Seen by Major-General Sir John Rose Bradford, who advised exploration of the chest and, if necessary, pericardiotomy. April 21st: Condition worse, cough, dyspnoea and pulse-rate all increasing. An X ray photograph which was taken showed the pericardium distended with fluid.

Plate from Johnson Symington's "Atlas of Topographical Anatomy," indicating the probable path of the bullet, which appears to have punctured the pericardium and grooved the muscular wall of the heart.

Operation.—General anaesthesia with chloroform and ether, with preliminary morphia and atropine hypodermically. Twelve ounces of clear fluid were withdrawn from the left pleural sac, which was proved to be sterile. An incision was now made along the fifth rib and cartilage from the mid-line to the nipple-line, the fifth costal cartilage was resected, the fibres of the triangularis sterni muscle were separated, and the internal mammary artery drawn inwards. The

pericardium was now picked up and a vertical incision was made in it. Very little fluid at first escaped, but when the finger was insinuated between the right auricle and the pericardium and between the left ventricle and the pericardium cloudy fluid escaped in quantity, which on bacteriological examination was found to contain a short streptococcus. Glove drains were inserted to the right and left inside the pericardium and the wound was closed.

April 23rd: Breathing and cough much easier; drains removed. Pulse and temperature now gradually fell and the wound healed by first intention. Four weeks later he was evacuated to England. The cough and dyspnoea had disappeared, the cardiac dullness was much less, and there was no friction.

Subsequent inquiry two months later showed that his improvement was maintained.

THE MOLYBDENO-TUNGSTEN ARC IN THE TREATMENT OF VARIOUS SUPPURATIVE LESIONS.

(As used at a Divisional Rest Station and a Stationary Hospital, Italian E.F.)

By B. MICHELL YOUNG, M.R.C.S., L.R.C.P., D.P.H.,
CAPTAIN, R.A.M.C.(T.)

THE very numerous cases of old wounds, ulcers of various parts of the body, carbuncles, inflammations of the cutaneous tissues, and such like, have presented many difficulties to obtain rapid healing. Many methods have been employed with more or less success to lessen the period during which the man is incapacitated from duty. In March, 1917, I first used the molybdeno-tungsten arc on skin lesions, and suggested that it should be employed for the treatment of this class of case. The lamp was erected first at the divisional rest station, the necessary current being obtained from a repair-motor lorry's engine situated some 400 yards away. This was satisfactory. Afterwards it was connected to the town-supply at the stationary hospital.

The cases selected for treatment were chiefly those which were of considerable duration and which showed little or no improvement obtained by previous methods of treatment. The exposure given was generally three minutes at a distance of 50 cm. from the arc. The dressings used were practically in all cases of gauze damped with sterile water; in a few normal saline was used. This was adopted as it was desirable to eliminate any cause of improvement, or the reverse, other than the effects of the ultra-violet rays produced by this arc. I am basing my remarks on my own experiences and on a series of cases treated by Lieutenant-Colonel Wells, to whom I am indebted for kindly forwarding to me his notes and observations. In considering the various effects and non-effects produced, the cases tend to group themselves into acute lesions, stationary or inactive lesions, and chronic. In the acute lesions, frost-bite, carbuncles, large areas of inflamed and ulcerated skin responded readily. A series of frost-bites especially, with loss of tissue, afforded effective comparison, as only one limb was exposed to the light, while the other was treated with the usual methods. In every case the light caused prompt healing in about eight days, while the other remained unhealed. In 38 cases of generalised sores many were healed more speedily by this method of treatment.

Ulcers of heels and toes require relatively more exposures according to the length of time they have acquired their indolent condition. But once the effect is produced they steadily progress in the process of repair. Occasionally a case is met which refuses to respond. For this I can advance no reason; one such occurred in this series—possibly specific.

Taking the whole series, the exposure of three minutes is sufficient in the first group and good results were obtained, but this should be increased even to causing erythema of the surrounding tissues, until evidence of activity in the sores is produced in those obstinate cases, and possibly more rapidity of healing would be obtained. Cases of bubo which had been incised were treated from the outset with daily exposures of three minutes, and each healed in eight days, leaving a narrow healthy linear scar, comparing favourably with cases treated in the usual way; and my experience shows that, speaking generally, there is an absence of thickening and puckering in cases so treated.

Some patients develop an erythema in the surrounding skin (especially those of the fair type) in response to the

light, but increase of distance or interposition of the quartz globe neutralises this effect. The skin soon becomes tolerant, when full exposures may be given.

The lamp now employed is known as the "meridian" automatic feed arc fitted with the new molybdeno-tungsten electrodes. It is connected in the usual manner with the ordinary house supply, and is a suitable contrivance for all voltages above 100 volts, both direct and alternating current. The observations which these cases afford lead one to the opinion that this method of treatment is useful for shortening the incapacity for duty.

A PLASTIC VOCAL CORD.

By FERRIS N. SMITH, B.A., M.D. MICHIGAN,
HON. CAPTAIN, R.A.M.C.

THE following case is reported because of the unusual possibilities which it suggests at this time, when many cases of traumatic aphonia are added to the usual list of such cases resulting from disease. The technique was quite original; no similar procedure has been found or suggested in the literature. The patient is the secretary-manager of a large home for aged Dutch people, and was in excellent health when last heard from in June, 1918.

J. C. H., aged 62, came for examination in January, 1917, on account of rapid loss of voice, some referred pain radiating to the right ear, and slight loss of weight. He gave a history of removal of a small mass from the right vocal cord and cauterisation three years previously. Inspection revealed a nodular, rough mass about the size of a split pea at the mid-portion of the free margin of the right true cord; this prevented apposition of the cords, causing the loss of voice. A small specimen for examination was removed through the laryngoscope. The pathologist reported "squamous-celled carcinoma."

In view of the previous history and findings a radical operation—hemilaryngectomy—was indicated, but on account of the man's occupation, which necessitated the retention of some speaking voice, I was loath to follow this procedure. The posterior end of the cord with its arytenoid attachment was apparently free from infiltration, and offered a foundation for the procedure which was carried out. There was a great deal to gain and very little to lose in the effort to reconstruct this vocal cord before resorting to the radical procedure. Further, any healthy mass of tissue which could be put in the cadaveric position of a vocal cord would furnish an abutment for the functioning cord and ensure spoken voice. The functioning arytenoid offered hope of some motion.

With the above considerations the following operation was conceived and executed in two stages at the Blodgett Memorial Hospital, Grand Rapids, Michigan, in February, 1917:—

Stage 1 consisted in the dissection and packing of neck structure about the larynx to produce an inflammatory barrier against infection of the deep planes of the neck after opening the airway and preparing the distal end of a flap to imitate the form of a vocal cord. This was done by making two short incisions to outline the lateral borders, dissecting the skin free from underlying tissues, planting a small piece of cartilage, and suturing a tuck or fold in the skin to include this cartilage. The crest of this fold was three-eighths of an inch above the normal skin level. The balance of the flap was not dissected until the second stage of the operation.

At the second stage a laryngotomy was performed, and the anterior three-fourths of the cord, with all soft parts in a wide area extending down to the thyroid cartilage, was removed. The skin flap, with a broad base in the supra-scapular region of the right neck and its prepared distal end just above the right nipple, was dissected. The distal end was trimmed to fit in the denuded area of the larynx in such a manner that the fold containing cartilage assumed the level of the former cord. It was sutured to the cord stump on the arytenoid and border soft parts with horse-hair. A tracheotomy-tube was inserted through the upper two tracheal rings and the larynx packed with bismuth paste gauze. The larynx was held slightly open with a Jansen mastoid retractor. The skin opening of the neck and chest was closed by undermining and sliding the skin.

The patient was placed in a bed which was considerably elevated at the foot. He was fed with a gastric tube. The skin flap was covered with warm, constantly changed, boric compresses, and the larynx was dressed twice daily.

On the eighth day the mid-portion of the pedicle of the flap showed signs of withering. This was resected on the ninth day, part of the base being returned to the neck. A small part of the inferior border of the larynx implant

sloughed, but this was not in a position to vitiate the result. The tracheal tube was withdrawn at this time and the larynx and neck closed, excepting the tube tract, which was lightly packed. Subsequent recovery, except for a mild bronchitis, was uneventful.

The patient had a hoarse, whispering voice immediately upon closure of the larynx. The voice quality constantly improved with the disappearance of the local reaction until it was functionally excellent, only a slight huskiness remaining.

Several improvements in technique have occurred to me since seeing the plastic work of Major H. D. Gillies at Queen's Hospital, Farnham, Sidcup. His method of tubing a long pedicle by suturing its raw edges would undoubtedly prevent the gangrene which occurred in my flap, and leave a clean, healed neck to deal with at the time of the major procedure. The distal end of the flap should be completely outlined by skin incision and resutured in place to increase its blood-supply, and the cord accurately reproduced, even to a thin edge, by shaping a piece of costal cartilage instead of using the thin septal cartilage. This should be done in the first stage.

The method is applicable to cases of hemilaryngectomy, either surgical or traumatic, if three stages are employed, the second stage to consist in removal of the diseased or scarred portion of the larynx and lining the deficiency with skin, leaving for the third stage a shaped cartilage implant to give stability to the larynx box and an abutment for the functioning cord.

Medical Societies.

ROYAL INSTITUTE OF PUBLIC HEALTH.

Discussion on the Prevention and Arrest of Venereal Disease in the Army.

A SPECIAL conference was held on Jan. 8th.

Lord SYDENHAM, chairman of the National Council for Combating Venereal Diseases, who presided, said that medical science in all its branches had been powerfully stimulated by the war, and victory had been gained over many of those diseases which used to cripple armies in the past. We understood now better than ever before that medical science and sound administration must always go hand-in-hand, and together could produce an immense improvement in public health. Public health and the happiness of the people went together. In so far as venereal disease could be arrested in the army it must be an immense gain and protection to the civilian population. During the war there had been an increase of infection among that population which would increase the risks to demobilised men.

The Policy of Silence.

Professor J. G. ADAMI, Colonel, C.A.M.C., read a paper opening a discussion on the Prevention and Arrest of Venereal Disease in the Army. He said that the performance of a physiological function which the individual in his heart of hearts knew to be in itself natural and desirable had to be regarded and taught as contrary to good morals. We found ourselves torn asunder between Peter and Paul; the Peter that is within us teaching us that what God has given us is clean and is to be enjoyed; the Paul, that woman is a snare and that even a bishop should have but one wife—and scarcely that. And as youth was largely irresponsible and the sense of social duty a plant of slow growth, which in some throughout life was choked by the weeds of personal predilection, it had followed that the whole matter of sexual conduct had for generations been surrounded with an atmosphere of insincerity, not to say hypocrisy. The "dead hand" of training began in early childhood, whereby we were taught to regard the open discussion of sexual matters as taboo; and there was the "dead hand" of schoolboy "form," according to which public acknowledgment of one's standing in relationship to moral matters, save on the part of those who had donned the cloth and become professional moralists, branded one as either a prig or a humbug. Happily, we were passing out of this phase.

What this policy of silence had cost the country and the Army during the last four years was awful to contemplate.

Before the war the annual reports of the Director-General had warned the Government as to the prevalence of venereal disease in the Army; a quarter of all admissions to hospital were due to this cause, but, with the war, no steps had been taken to render the regulations against harlotry more rigid. Our men had been in the venereal hospitals not by companies but by battalions. Each case had meant two months and more on the sick list, and weeks and months before the individual could be restored to full vigour at the front, if, indeed, there was not left a legacy of rheumatism, eye disease, and enfeebled general health.

The Position during the War.

When in the autumn of 1914 the first Canadian contingent arrived upon Salisbury Plain it was found that the Common Law of England and the Military Law were equally impotent to cope with the condition of affairs revealed. Harlotry in England seemed to be a protected but not a controlled profession. This, however, was also largely true of Canada, but the Canadian authorities did expect that in England in war time they would get willing help from local and London authorities in protecting the soldier. Of help there was little. Each week-end there poured into Salisbury Plain from London from 80 to 100 loose women, and it was not until under the Defence of the Realm Act in 1916 that the naval and military authorities in one area, where there had been a large outbreak of venereal disease, were empowered to transport out of that area those directly or indirectly concerned in the profession of prostitution.

He was convinced that the policy of frank dealing and open speaking on the subject was the only one that would improve conditions. Even at this late hour he begged the National Council for Combating Venereal Disease to influence the Government to publish a statement regarding the venereal situation in the Army in successive years of the war, in the different regions—at home, France, Mesopotamia, and the like—so that the country might know the extent of the trouble as it affected the Army, and, simultaneously, to obtain powers to make an investigation in selected areas or classes of the population into the frequency of either syphilis or venereal diseases in general in those areas or classes. Let the situation be known and faced. Had the medical profession, the National Council, and the Government spoken out at the beginning of the war the well-being and happiness of the country and the conditions of our troops would to-day have been very different from what it is. In 1912, before the war, the Surgeon-General at Washington had published outspoken regulations directing all soldiers returning to camp to state whether they had exposed themselves to the possibility of venereal infection and detailing the early preventive treatment to be given to those who had been exposed. This he (Colonel Adami) had reported upon to the War Office, but the "dead hand" had prevented its adoption for close on two years.

Preventive Measures and their Results.

With regard to the methods in vogue in the overseas military forces of Canada it had been found in practice that there was no one procedure which was effective in arresting venereal disease in the army; it was necessary to employ a combination. The Director-General had put into force all the methods save one (court martial)—education, warning, recreation, diversion, protection, isolation, prophylaxis, and penalties.

With regard to early treatment every Canadian orderly medical room in England was an early treatment centre, open day and night, with trained N.C.O.'s to supervise and see that the soldier carried out fully the instructions given. For those on leave in London there were open day and night two early treatment centres, at Southampton-street and at Victoria, and another treatment was given on their return to their units. The Dominions worked together, and if no Canadian centre was open the men could go to an Australian or New Zealand centre. The Canadian authorities in their talks to the men on parade made a point of emphasising that neither prophylactic nor early treatment assured absolute immunity to venereal infection. Experience had shown that even under expert supervision no procedure was free from occasional failure. The Canadian authorities firmly believed that if the Army and the populace in general were advised that absolute deterrents existed when this was not the case, there

was a possible danger of their employment leading, not to diminution, but positive increase in the spread of venereal disease. This had actually happened in Germany.

One set of statistics alone, he thought, would eloquently show the effects of the campaign undertaken by the Director-General through Lieutenant-Colonel Amyot and his staff. During the month of September, 1918, from nearly 42,000 Canadian troops in Great Britain there were admitted to hospital suffering from venereal diseases 960 cases, practically a battalion. During the month of September, 1918, from among 110,000 Canadians in Great Britain there were 750 similar admissions. In two years the venereal incidence had been reduced more than 66 per cent.; it stood now at less than a third of what it did two years ago. Had they continued at the same rate the admissions during the month of September, 1918, would have been, not 750, but over 2500—that is, two battalions and a half out of action.

The Dangers Ahead.

Throughout the war the soldier had been well cared for with regard to venereal disease, but it was the civil population that to-day constituted the grave danger, and nothing had been done to meet the emergency. When our soldiers returned and were feasted, made drunk, solicited, and fell, there would be no medical orderly-room to go to after demobilisation, no provision for early treatment, no N.C.O. to see that the elaborate toilet was duly performed. The soldier would receive and not give, and, admitting that the provision of prophylactic treatment to an uninstructed public might well result in the spread rather than in the production of the disease, he was strongly of opinion that the soldier before demobilisation should be provided with the means of prophylactic treatment, should be advised where and how to obtain "tubes" without difficulty, and, moreover, be given precise detailed instructions as to the method of employment. For the good of the country he saw no other possible course. To those who, in the supposed interests of morality, would still maintain the policy of silence he could only repeat what he had said in Westminster in July to the National Conference upon Maternal and Infant Welfare: "Which is the more immoral act, to advise a man how to prevent infection if he has transgressed the moral code, or calmly and coldly to look on without moving a finger while, through ignorance on his part, the innocent wife and children are diseased, and they and the community suffer through generations?" Unless something were done and that immediately the next few months would see a spread of venereal disease in this country that for generations would cause the Empire to suffer. Now, if ever, it was well to repeat His Majesty's famous exhortation, "Wake up, England."

Discussion.

In the discussion which followed Professor HUGH H. YOUNG, Colonel, U.S.M.C., strongly advocated the use of prophylactic treatment which had been enforced in the United States Army in 1912. In the following five years venereal disease was reduced nearly 50 per cent. During the war as far as possible large centres like Liverpool and London were avoided in sending troops through England, and in France brothels were placed out of bounds with very gratifying results. Some of the brothels in that country were terrible places, accommodating as many as 1000 or 1500 men in the course of an afternoon or evening. Even granting that the women there appeared to be healthy on medical examination, when men followed each other in such rapid succession the women became carriers of the disease. In one case a boy doorkeeper who had frequent connexion with these women was found to be actively syphilitic. The women acted as temporary hosts for the disease and sources of danger regardless of the most careful medical examination. This was a point which he thought was new. The situation in London and other big cities was a disgrace, and it was a crime that the police should not be able to arrest the women whom they knew to be prostitutes. The soldiers would come back to a civil population presenting far more dangers than the soldiers themselves. Prostitutes were greater criminals than thieves, for what was the loss of a little money compared with the health of the country's manhood? The calomel packet with a leaflet giving full instructions for use on one side and moral instruction on the other, if thought necessary, should be on sale in slot machines at 1d. throughout the country.

Professor WILLIAM F. SNOW, Lieutenant-Colonel, U.S.M.C., who is in charge of the Repression of Venereal Diseases Department of the Surgeon-General's Office, United States, said, starting on the basis that continence was the best remedy, the American Government had provided all kinds of entertainment as a counter-attraction for sexual excitement. The public were notified as to what was being done and told that the Army would be affected by the way the public authorities looked after its manhood. The public had never opposed any of the Army's proposals. There was no conflict between morals and public health. He did not fully agree with Colonel Young as to the use of slot machines, because the packet gave the man the opportunity of making his own diagnosis and treating himself, which might not be done properly. If all dispensaries opened their doors to the man who said "I have just exposed myself" he did not see any moral danger in it.

Major-General Sir FRANCIS LLOYD, who had commanded the London district for the past five years, said the question ought to be dealt with from every point of view.

Sir JAMES W. BARRETT, Lieutenant-Colonel, R.A.M.C., late Australian A.M.C., in giving his experiences with Australian troops, said that moral forces had been brought to bear, but it was only after the use of prophylactic methods that any general good had resulted. In regard to the general question, the root cause of the whole trouble was the marriage age. While that age remained on an average 30 for men and 27 for women, there was nothing that would prevent the sexual relationship of many people.

Surgeon Captain P. W. BASSETT-SMITH, R.N., detailed the voluntary prophylactic methods in use in the Navy.

Sir ARTHUR NEWSHOLME considered that the Canadian and American methods of meeting the venereal peril were the most complete that had yet been devised, but he was imbued with a sense of despondency at the relative ill-success of the results. If under military discipline the results were disappointing, what prospect of very rapid or immediate success was there under the free conditions of civilian life? When a public health measure came in conflict with morals the first would suffer, and if a public health measure were to be carried and applied with success moral sentiment must go with it.

Professor J. A. AMYOT, Lieutenant-Colonel, C.A.M.C., said that the men were given every possible means of treatment, and the results had been satisfactory.

Dr. HELEN CHAMBERS was of opinion that the reason for the ineffective way of dealing with the matter in the past was the fact that the woman's point of view had been ignored. The time had come when women should receive instruction from the medical women of the country. The scandalous state of the streets should be dealt with by women police. She pleaded for institutions where patients suffering from venereal disease could be sent as infectious patients and retained till cured, and where the nature of the disease would not be made public.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Exhibition of Cases and Specimens.—Abderhalden's Pregnancy Reaction.

A MEETING of this section was held on Nov. 22nd, 1918, Sir J. W. MOORE, the President of the Academy, being in the chair.

Dr. R. D. PUREFOY showed a specimen of Tubal Pregnancy, which was discussed by Sir WILLIAM SMYLY and Dr. BETHEL SOLOMONS.

Dr. SOLOMONS showed a specimen of Sarcoma of the Cervix which he had removed from a woman aged 50. She had been married 26 years and had 11 children, the youngest of whom was 11. She complained of a feeling of "womb falling" after the birth of her last child, but the symptoms vanished until 14 days before she consulted him. On examination it was found that a large mass, about the size of a large grape fruit, filled the vagina and was connected with the posterior lip of the cervix, with which it was incorporated. The tumour was removed, and as the cervix was hypertrophied it was amputated. A pathological examination by Dr. J. T. Wigham revealed the growth to be a spindle-celled sarcoma, with a large amount of hyaline degeneration of the capillaries, forming a kind of cylindroma. Following

this report, Dr. Solomons performed Wertheim's hysterectomy, and convalescence was without incident. The uterus on examination proved to be normal. He commented on the silent growth of the tumour, with absence of symptoms, which was typical of these rare cases of primary sarcoma. He thought that a radical hysterectomy should always be done in this class of case.

Dr. J. T. WIGHAM thought that the sarcoma, although malignant, was, if one might call it so, a benign form of sarcoma.

Dr. PUREFOY said that sarcoma limited to the cervix uteri was rare. In very young subjects myxosarcoma was sometimes seen springing from the cervix in the form of numerous small cysts, but its removal was generally followed by recurrence. Notwithstanding the pathologist's opinion, he was inclined to regard Dr. Solomons's case as one of uterine fibroid showing sarcomatous degeneration.

Sir WILLIAM SMYLY showed Two Tumours of the Mesentery removed from a patient in the Adelaide Hospital. The patient had a large cystocele which protruded through the vulva and caused much difficulty in emptying the bladder. On examination a tumour was discovered in Douglas's pouch which was supposed to be ovarian. After performing an anterior colporrhaphy the abdomen was opened and the tumour, which was exceedingly friable, was drawn out and found to be intimately connected with the intestine. A second tumour was discovered higher up in the mesentery. The tumours, which were thought to be malignant, were removed, together with about two feet of the ileum and a large piece of mesentery, and the severed gut restored by a side-to-side anastomosis. The patient made an uneventful recovery.

Captain J. SPEARES, who examined the specimen, said that the edges of the tumour were tubercular, but the central portion was so necrotic that it was impossible to diagnose the condition.

Dr. W. M. CHOFTON read a paper on Abderhalden's Pregnancy Reaction and Beard's Theory of the Alternation of Generations in Vertebrates. After describing the nature of tissue digestion of normal foodstuffs and abnormal substances given parenterally, he showed that the substrate—viz., the placenta—with the possible exception of the syncytial layer, could not possibly be considered foreign or disharmonious, and that, therefore, no specific ferment would be found for it in the maternal system. On the other hand, if Beard's theory was correct, the cells of the chorionic villi, &c., belonging to the phorozoon or asexual generation were foreign or disharmonious, and therefore a specific ferment would be formed to their protein which could be recognised by a complement fixation test. He criticised Abderhalden's method of detecting the presence of his protective ferments.

LECTURES ON INFANT CARE.—On Mondays, from Jan. 27th to April 14th, at 5.30 to 6.30 P.M., a course of 12 advanced lectures on infant care, for nurses, health visitors, teachers, infant-welfare workers, and others, will be held at 1, Wimpole-street, London, W., under the auspices of the National Association for the Prevention of Infant Mortality. The course is in preparation for the advanced certificate of the Association. The fee for the course is 5s. and for a single lecture 1s. On Thursdays, at 7 to 8 P.M., from Jan. 23rd to April 10th, a similar course of elementary lectures, in preparation for the creche nurses' certificate, arranged by the Association, together with the National Society of Day Nurseries, will be held at the Midwives' Institute, 12, Buckingham-street, Strand, London, W.C. To secure this certificate students must take 12 months' training and gain a certificate for proficiency at an approved day nursery, attending two courses of 12 lectures, of which this is the first. The fees are 10s. for the course or 1s. for a single lecture. Tickets from Miss Halford, secretary, National Association for the Prevention of Infant Mortality, 4, Tavistock-square, London, W.C.1, or from Miss Maddock, secretary of the National Society of Day Nurseries, 13, Victoria-street, London, S.W.1. A further special course of 12 lectures on infant care for health visitors, midwives, school teachers, voluntary health workers, and committees of nursing associations, will be held at the University Museum, Oxford. Some local authorities now have the power under the Maternity and Child Welfare Act of August, 1918, to defray the expenses of their workers in attending lectures such as these.

Reviews and Notices of Books.

War Story of the Canadian Army Medical Corps. Vol. I. By J. GEORGE ADAMI, M.D., F.R.S., Temporary Colonel, C.A.M.C. Published for the Canadian War Records Office by Colours, Ltd., and the Rolls House Publishing Co., Ltd. 1918. Pp. 286.

Sir Robert Borden, in opening an admirable collection of Canadian war pictures at the Royal Academy, London, on Jan. 4th, spoke of the inspiration he found in witnessing the triumph of spirit in Canadian hospitals over dull pain and monotony of long weary months, and that the inspiration was not lacking on the side of those who devoted their services to the care of sick and wounded is abundantly evident from the pictures themselves as well as in the story of the work of the Canadian Army Medical Corps told by Colonel Adami in a book to which Sir Robert Borden contributes an introduction. The record is intended, first of all, for the actual men of the corps, to whom, and to whose children's children, the wealth of personal detail will be of surpassing interest. But to the non-Canadian reader the story has the freshness of an adventure. The first volume, which is in our hands, deals with the medical service of the first contingent of Canadian troops up to the autumn of the year 1915. Canada being in the happy position of having seen little active warfare since 1812, the C.A.M.C. had to work out its arrangements largely as it went along. The Riel rebellion in 1885 necessitated the appointment of medical officers to the field force, and it was in this little campaign that a surgeon-general was first appointed at Ottawa. The wounded were few and sickness was slight in a campaign on conspicuously healthy terrain. It was as recently as 1896 that a definite medical subdepartment was created to the militia, when the late Sir Frederick Borden, himself a medical man, became Minister of Militia.

The story of the organisation of the corps during the following 20 years is of more than ephemeral interest. Appreciation of the value placed upon research is one of the strong traditions of the corps, with the result that research was carried on in the field, and No. 5 Canadian Mobile Laboratory has formed the background of a number of articles of permanent value which we have published in our own columns dealing with such practical matters as chlorination of water, mosquito prevention, and sundry aspects of trench fever. The use of poison gas as a weapon of offence was a terrible experience in which the C.A.M.C. was the first to participate. The diary of Thursday, April 22nd, 1915, cannot now be read without breathless interest, and the enterprise of Lieutenant-Colonel Nasmith in reporting almost at once on the nature of the attack and the means desirable for facing it may count as one of the achievements of the corps. Alongside the Turcos staggering back through the lines, dazed and weaponless, ran numbers of Belgian hares escaping from the gas and already so affected by it as to be knocked over without effort by the canteen cooks. Incidentally, poison gas had one thing to recommend it: Colonel Adami records that it materially reduced the live stock in the dug-outs and had an excellent potency in destroying the parasites of "that most irritating and most humiliating skin disease"—namely, scabies.

The C.A.M.C. is happy in its biographer, and the concluding volume or volumes will be awaited with keen anticipation.

The Organs of Internal Secretion, their Diseases and Therapeutic Application: A Book for General Practitioners. By IVO GEIKIE COBB, M.D., M.R.C.S. Second edition. London: Baillière, Tindall, and Cox. 1918. Pp. 274. 7s. 6d.

WHEN the physiology of the internal secretory organs has been so far elucidated, and the effect upon them of disease and their therapeutic application have been so fully studied of late years, some such work as this was needed in order to give the busy practitioner a simple lucid account of the rôle of the ductless glands, together with a practical guide to their means of treatment. The first edition was published in 1916. The second edition has been revised and brought up to date, and a chapter dealing with the relation of the internal secretions to functional nervous disease has been added, and will be found a useful addition at the present time.

Clinical Case-taking. By ROBERT D. KEITH, M.A., M.D. Aberd. London: H. K. Lewis and Co., Ltd. 1918. Pp. 104. 3s. 6d. net.

THIS is an excellent little book for the junior hospital student, being simple, clear, and concise. It was originally written for the students of the King Edward VII. Medical School, Singapore, so that the question of common tropical diseases is more than usually prominent. The introductory chapter gives a useful résumé of the scheme of case-taking, which is described and expanded in the following chapters, and the student cannot do better than have it at hand when examining a patient, and follow it out in every detail. Perhaps here at home, where, generally speaking, there is no language difficulty and time is available in which to deal fully with each case, we should be inclined to bestow more care and trouble in investigating the previous and family history than is here suggested, but that is a minor defect in an otherwise valuable little manual.

Differential Diagnosis. Vol. II. Presented Through an Analysis of 317 Cases. By RICHARD C. CABOT, M.D. Second edition, revised and illustrated. London and Philadelphia: W. B. Saunders Company. 1918. Pp. 709. 25s.

THE essence of the manner in which the subject of differential diagnosis is treated in these volumes is contained in the subsidiary title. The method is new and very instructive. This volume treats of the differential diagnosis of 19 prominent symptoms, and includes chapters on abdominal and other tumours, vertigo, diarrhoea, dyspepsia, hæmoptysis, hoarseness, pallor, &c. The cause of each symptom is first given and the relative frequency of its occurrence in various diseases is shown in tabular form, after which the cases are described and discussed and the outcome recorded, whether recovery or otherwise, or the findings either at operation or post mortem. The reading of such a book as this is the next best thing to a course of post-graduate clinical study.

Materia Medica and Therapeutics: An Introduction to the Rational Treatment of Disease. By J. MITCHELL BRUCE, M.A., LL.D. (Hon.) Aberd., F.R.C.P.; and WALTER J. DILLING, M.B., Ch.B. Aberd. Eleventh edition, revised to correspond with the War Amendments of July, 1917, and March, 1918. London: Cassell and Co., Ltd. 1918. Pp. 675. 9s.

THIS edition was being prepared when the changes were being made in the British Pharmacopœia consequent on the scarcity and increasing cost of many of the drugs in general use. The original formulæ appear as before, but the reader is referred in each case to a War Emergency Formulary at the end of the book, where the temporary substitutes are described. Many new remedies are noted, and such measures as electrical treatment, massage, and exercises are described more fully than before.

Aids to Medical Diagnosis. By ARTHUR WHITING, M.D. Second edition. London: Baillière, Tindall, and Cox. 1918. Pp. 167. 3s.

"AIDS" of any kind are to be deprecated unless used in the manner for which they were intended. Students of the less ambitious sort are tempted to rely on manuals of this size in the wrong way, and to regard them as "cram" books instead of setting themselves to the study of medicine in its fuller and larger aspects. Nevertheless, such a book is useful, provided it be looked at from the proper standpoint. These little "Aids" are of such a size that they can be carried about in the pocket, and are valuable for reference during, for instance, the examination of a patient. There are a few slips which should be corrected in a subsequent edition. On p. 45 it is stated that the characteristic feature of diseases of the blood is pallor; this is, of course, not so in all blood diseases. With regard to "scurvy-rickets," it was shown by Cheadle in 1878 that this name was a misnomer. The disease is usually known either as "Barlow's disease" or "infantile scurvy," the rachitic features being by no means always present and being entirely distinct, etiologically, from scurvy. Sporadic cretinism would benefit by a fuller description than that given. Perhaps the meagreness of the description is due to

the fact that infantilism is not dealt with in any form, and this, we think, is a disappointing omission, as many forms of infantilism are by no means uncommon, and the main diagnostic features would take up little space. Dry pleurisy should surely not be included under "Diseases with Dullness on Percussion," a dull percussion note being said to be one of the diagnostic signs. Books of this kind have their uses, but students should be warned against placing too much dependence on them to the neglect of fuller reading.

JOURNALS.

Reconstruction. A Monthly Bulletin published by the Department of Soldiers Civil Re-establishment, Canada. October, 1918.—An Order in Council has been passed to protect discharged soldiers with amputations from the competitive attention of representatives of private manufacturers of artificial limbs. Sir James Lougheed, the Minister responsible, points out that no man with an amputation can ever feel he is bodily complete, however long he has been wearing the most perfect artificial limb possible. Although no trouble or expense has been spared by the Government to provide the best limb available, a number of manufacturers and vendors of artificial limbs have endeavoured to convince returned soldiers that the Government issues are clumsy and of little value. All artificial limbs and appliances manufactured by the Government are stamped; the Order in Council enacts that no person to whom an artificial limb or appliance is issued shall transfer, exchange, or otherwise relinquish such limb except with the written consent of the Minister, nor must such limbs or appliances be altered without similar consent. Any person disparaging goods manufactured or issued by the Department is liable to a fine. A blinded officer who after training at St. Dunstan's has been carrying on his former profession, that of electrical engineer, has been appointed to the vocational staff to represent the Government in dealing with blinded soldiers. These men will be persuaded, if possible, to accept the Government offer of training at St. Dunstan's before leaving England. 1347 men have already graduated from industrial re-education courses; 1877 are at present under instruction. Since the work began only 339 men have refused to take up a course; 558 have discontinued for various reasons. This number, however, includes 111 men whose course has been suspended for a short time to enable them to take part in agricultural production.

The Military Surgeon.—In the issue of this journal for October, 1918, Colonel Victor C. Vaughan and Captain G. Palmer complete their account of the infectious respiratory diseases in the U.S. Army last winter. These diseases were specially frequent among men from country districts and particularly from the Southern States. This is in great measure due to want of acquired immunity, but even more to want of education in sanitation, and the correlated personal carelessness. In the camps most attacked were men who had grown up in bad sanitary surroundings and who did not know how to look after themselves. Consequently they had, many of them, before entry, become infected with hookworm and malaria and venereal disease, and classes had to be held to teach them the use of water-closets and toilet paper. They were unaccustomed to the better food of the Army; they did not wash their hands before meals; they expectorated everywhere and could not see any harm in that; they required more bedding and clothing than others and they were easily fatigued. As very few were immune they rapidly developed these infections. The better the hospital accommodation in the camps, the more quickly cases "going sick" were sent there, the fewer the deaths from pneumonia. Overcrowding is considered a cause of infectious disease prevalence, but little weight is given to that, and ventilation is hardly mentioned. Still, it is noted that officers, who are less crowded, more often escape these diseases. It is observed that officers, too, are generally less fatigued. In one camp the men who did guards suffered most; the quartermaster's staff, the cooks, and the officers escaped. Faulty quarantine also did great harm. It is hoped that in future recruits will be sent to observation camps to begin with, there to be quarantined, vaccinated, and taught hygiene and a little physical drill before they are transferred to the large camps to undergo military training.

A TRIBUTE TO SIR LEONARD ROGERS, L.M.S.—The Calcutta School of Tropical Medicine, which already possesses a portrait of Sir Charles Farley Lukis, has now memorial to the work of Sir Leonard Rogers, the professor of pathological medicine in Calcutta Medical College. bust of Sir Leonard Rogers has been unveiled by Lord Ronaldshay.

THE LANCET.

LONDON: SATURDAY, JANUARY 18, 1919.

Industrial Efficiency and Preventive Medicine.

THE physical inefficiency of our industrial classes is one of the spots in our social organisation which, hitherto dark, the searchlight of war has all too brilliantly illuminated. Our national unreadiness for war was most marked not in the fighting forces but in the industrial organisation behind these forces. Our Army may, as regards size, have been "contemptible," but it was constructed on a model which withstood the test of tenfold multiplication. The call of the Army for men, on the other hand, laid bare an appallingly low standard of physique among men of fighting age; and when this call had, so far as was possible, been met, our industries, particularly the munitions industry which supplied the fighting forces with their life-blood, had to rely mainly upon the fit in our population, who were over military age, and much admirable female labour. Then the discovery was made that owing to the conditions of industrial life during the past half-century there were but few skilled craftsmen over the age of 50 who had not already "gone West." Now the war is over, and attention is being given to reconstruction and reorganisation; and nowhere is fresh effort and new work more called for than in trying to ensure for the future generation a higher standard of health among the industrially employed. Two questions call for prompt reply: Who is to be entrusted with the effort which is needed? and How is the effort to be carried out?

The questions are really one, for the methods adopted will to great extent depend upon the agency selected. In the past what has been done to improve the lot of the worker has been carried out by the Home Office administration of the Factory Acts, Shops Hours and Mines Regulations Acts, and the Coal Mines (Minimum Wage) Act, and a decision must now be arrived at as to whether action concerning health and industry in relation to labour is in the future to be administered by an office destined, according to the Haldane Committee¹ to become a Ministry of Justice. If the decision is against the Home Office continuing in charge of the work, should the administration be entrusted as a health question to a new Health Ministry, or as an employment matter to the Ministry of Labour? There is much counsel, and as usual the old adage "In the multitude of counsellors there is wisdom" falsifies itself, because each counsellor counsels differently, and the adage does not indicate how the

wisdom is to be sifted out from the multitude. For once, however, on an admittedly difficult question, we have before us advice flowing from two separate sources which is in close agreement. First, the Haldane Committee are definite and explicit:

"We are satisfied that the inspection and regulation of conditions affecting the health and safety of industrial workers are matters for which the Minister of Employment, and not the Minister of Health, must be responsible to Parliament. . . . The ordinary methods of consultation (between two departments) will probably require to be supplemented from time to time by the appointment of special committees, on the principles which have proved conspicuously successful in the case of the Health of Munition Workers Committee, to advise the Minister of Employment upon problems of industrial health which are new in kind or have assumed a peculiar importance or urgency."

Secondly, the Association of Certifying Factory Surgeons² has recently prepared a report upon this subject and state:

"We think, however, that early arrangements should be made for transferring the whole of the Factory Department from the Home Office to the Ministry of Labour. It appears to us that the Ministry which has the economic problems of labour under its care and direction is the proper body to take charge of occupational health and safety problems, but we are particularly influenced in our view by the conviction that Labour Exchanges could be made into such useful adjuncts to medical examination by securing for young people employment suited to their physical condition. We are also of opinion that the health and welfare measures established by the Ministry of Munitions could be more suitably carried on by the Ministry of Labour than by the Home Office."

Clearly, then, the balance of opinion would favour that the Ministry of Labour (or, as the Haldane Committee prefer it to be called, the Ministry of Employment) should be entrusted with the duty of organising industrial health supervision. There remains for consideration—How is the end in view to be attained? An answer to this question is hardly to be sought from the Haldane Committee, for it was not within their terms of reference, but the report of the certifying factory surgeons contains many valuable suggestions as to the way in which the work could be done by linking up the Employment Exchanges with the Medical Factory Service, especially in relation to juvenile employment. We would here express a word of regret that adults are not more fully considered by the Association of Certifying Factory Surgeons, feeling, as we do, that only by close and intimate association between the Employment Exchanges and the places of employment can any coördinated attack be made upon what is to-day the most serious economic loss in industry—that due to the turnover of labour, and the resulting wastage of workers. Our readers should in this connexion be familiar with the admirable report issued from the Medical Research Committee on the wastage of female labour in munitions factories.³ Apart, indeed, from the serious loss thus indicated, social economy is not served by sending A 1 men to work which could be carried out by C 3 men, while to send C 3 men to attempt A 1 work is homicidal.

We desire to see every employer of labour with the whole- or part-time services of a doctor at his disposal to advise him on welfare and health

matters; to examine new workers; to watch over the health of his whole staff; to supervise the hygiene of his establishment as regards ventilation, light, temperature, cleanliness, and first-aid appliances; to advise and help the Welfare Department; to be, in fact, an industrial medical officer of health. Such officers should also be retained to advise the local employment exchanges as to the type of worker to be drafted to this or that trade or process. They should also be employed to conduct the periodical examinations of juveniles industrially employed as will be required under the provisions of the Education Act, 1918, and so to coördinate the school and factory medical supervision. Such local officers would require to be directed and assisted by a medical organisation controlled from headquarters—a nervous system of which the local service would be the peripheral end-organs. The value of such a medical organisation, associated with the Government Department concerned with employment, would be incalculable not only to carry out investigations and assist research into the effect of industrial conditions and hours of labour, but also to influence the adoption of health reform based on sure knowledge so obtained. Probably in the whole field of preventive medicine nothing more urgently calls for action than the establishment of organised medical supervision of employment on sound lines; probably no field promises in return for cultivation a finer harvest of results. In the past unfavourable conditions of employment, overwork and fatigue have caused irritability and labour unrest, impaired physique and disease.

"The subject of industrial efficiency in relation to health and fatigue is in a large degree one of preventive medicine, a question of physiology and psychology, of sociology and industrial hygiene. Without health there is no energy, without energy there is no output. More important than output is the vigour, strength, and vitality of the nation."

Thus the final report of the Health of Munition Workers Committee in the sentences we quote summarises the whole great truth. In the immediate future the nation, as never before, must obtain industrial efficiency through preventive medicine.

Accurate Diagnosis in Appendicitis.

DURING the last 30 years the rôle of the appendix vermiformis in health and disease has been a frequent topic both in medical and lay circles. Before that time little of ill had been laid to its charge; if a criminal, its crimes remained undetected. But at the present time it has become the pathological scapegoat, every pain and ache below the diaphragm casting suspicion upon the appendix; so that the hand of every surgeon is against it. In spite of the attention that it has received the fact remains that the normal appendix has not been sufficiently studied, not only in its anatomy but also and especially in its physiology, and there are questions as to the activities of the appendix which have not, hitherto,

received any very definite answers. The means to accurate diagnosis are not yet at our disposal. In the present issue of THE LANCET is an important paper by Dr. E. I. SPRIGGS on the normal anatomy and physiology of the appendix as revealed by the aid of X rays, and the paper is illustrated by accurate coloured drawings and a large number of admirable skiagrams taken by Mr. O. A. MARXER. The X rays have already been employed to a certain extent in the investigation of the appendix but the observations in this paper are more complete and more thorough than anything that has preceded them.

The first thing to be settled by Dr. SPRIGGS and his collaborator was the best material for the opaque meal when it is required to demonstrate the appendix, and it was found that buttermilk and barium sulphate formed the most suitable opaque meal. Moreover, the best results were obtained when the bowel had been previously thoroughly emptied by castor oil. With these preliminaries adjusted, much physiology was made clear by the ensuing observations. In the first place, it became certain that even in health some of the contents of the cæcum enter and leave the appendix, that it fills when the cæcum fills, and that when the contents of the cæcum pass on their way the appendix discharges what it has contained, though sometimes the emptying of the appendix may be a little delayed. In the young, indeed, the appendix may fill and empty several times while the cæcum is still full. It is also certain that in the young the appendix is much more lively than in those who are old. The appendix was seen by Dr. SPRIGGS to move actively; some times the movement occurs as the organ fills, and sometimes without any reference to the passage of material into or out of it. So that we have learned much from these researches as to the conditions of the appendix when it is normal, something of its physiological movements, but, alas! we have learned nothing to enable us to answer the important question whether the appendix has a function or not. That it may be removed without any obvious impairment of health is no proof that it is valueless, for the spleen can be, and has many times been, removed without the least harm resulting, and yet no one would deny that the spleen is of functional importance. The persistence of the appendix, and its active movements, certainly do suggest that it may have some function in the economy of the human body, small though that function may be.

These investigations further afford us much insight into the pathology of the appendix, although such technique can be employed only in cases of chronic appendicitis, for in the acute form the time needed to prepare for and to take the skiagrams must not be spared. But in cases where the diagnosis of chronic appendicitis has not been definitely made, and when there are obscure pains in the abdomen of long duration and uncertain cause, it is all to the good if a diagnosis can be made whether there is or is not definite disease of the vermiform appendix. When sufficient skill

* Health of Munition Workers Committee, Final Report, Industrial Health and Efficiency. H.M. Stationery Office (Cd. 9065), 1918. Price 2s. net.

has been acquired and when adequate care is taken it is found that very great reliance can be placed on the appearances presented by the skiagrams, and Dr. SPRIGGS and Mr. MARXER are to be heartily congratulated on their work. They found that it is often necessary, as in the case of the X ray diagnosis of disease in other parts of the alimentary canal, that repeated observations should be made to determine whether the conditions indicated are temporary or permanent. By these means they have found it possible to say whether there are constrictions or kinks in the appendix, whether concretions are present or not, whether the appendix is dilated, and whether adhesions exist. If the appendix always occupies the same position, if manipulation with the hand cannot induce it to move, then we may be sure that adhesions exist which chain it down to one place. In one case brought forward by the authors the appendix gave all the indications of being healthy and empty, yet at a subsequent examination two small shot were seen in it; but they gave rise to no symptoms, though the appendix emptied itself more slowly than before, for it was found to contain some barium sulphate 24 hours after the cæcum had discharged its contents. The appendix was examined every week, and three weeks later the shot had gone. This interesting observation shows us that foreign bodies may not only enter but may also leave the appendix. That the diagnosis made by the X rays may be considered trustworthy we learn from Dr. SPRIGGS, for in all the cases in which a subsequent operation was performed the condition found was that which had been recognised on the skiagram. Thus there can be no doubt that we have in the use of the X rays a valuable aid in the diagnosis of chronic appendicitis, just as there can be no doubt that the information needs highly skilful record. The work of Dr. SPRIGGS and Mr. MARXER has been very thorough, and must have entailed great expenditure of time and pains well directed. The illustrations showing the actual skiagraphic appearances are sufficient guarantees of the practical worth of the research, for by the methods adopted information can be obtained that is otherwise unavailable—information which may either render operative measures unnecessary or much reduce their duration.

In this issue of THE LANCET, also, Mr. S. T. IRWIN, of Belfast, gives a careful classification of the forms of acute appendicitis, supported by some effective coloured drawings, and he claims that it is possible to discriminate definitely between the several varieties before the abdomen is opened, though many surgeons will hesitate to concur. He points out that in the obstructive form the attack always begins with the sudden onset of pain, and he believes that this suddenness is characteristic of the obstructive form, certainly the most dangerous of all the varieties. He shows that it is the obstructive form which on rupture gives rise to widespread peritonitis, for the pus which the appendix contains is at high tension, and only rarely is it that adhesions exist to confine the infection. In these obstructive cases the essential

in the treatment is early operation, for the rate of mortality rapidly increases with delay, and few of the cases in which the appendix has given way end in recovery. Mr. IRWIN rightly insists that the remedy for the high mortality in cases belonging to this category lies in the earlier operation, and the possibility of this depends mainly on the doctor who is first called to see the patient. In only too many cases is the surgeon told that the doctor has not urged the need for an operation, that he has tried soothing remedies which sometimes succeed in masking the serious nature of the attack—even the cessation of pain, which not rarely occurs on the onset of gangrene, has been mistaken for real amelioration. With the medical profession lies the onus of impressing on the patient and his friends the necessity for an early operation if the patient's life is to be saved in these cases. Correct diagnoses should be made in cases where the symptoms are well marked and the history is clear. The illustrations accompanying Mr. IRWIN'S paper show appendices in varying conditions immediately after removal, and illustrate appearances which are, of course, completely lost in preserved specimens.

The Harvard Medical Unit.

AFTER three years of friendly coöperation with the British Army Medical Corps in France, the Harvard Medical Unit is passing through London on its way back to the United States. In 1915 Colonel HUGH CABOT gave up his assistant professorship of genito-urinary surgery at Boston, with Dr. G. C. SHATTUCK and a group of colleagues, determined to offer us any help they could during the war and to see the business through to the bitter end. The Harvard Unit consisted of American medical officers and nurses with English personnel, at first under the command of Sir ALLAN PERRY, and from October, 1915, on with Colonel CABOT as chief. A most excellent friendly feeling has prevailed throughout amongst the members of the unit and between them and their British helpers, and has been no mean factor in that close professional relationship which has been springing up between American and British officers. The position of the unit has enabled it to form independent views on the important topics of war-time surgery. Their experience, Colonel CABOT tells us, gives no support to the belief that any of the new antiseptics and ingenious methods of applying antiseptics will have any permanent place in surgery. No antiseptic has yet been produced which may not do as much damage to the human tissues as it does to the micro-organisms. Antiseptic, in distinction to aseptic, surgery has not, in the opinion of the unit, gained strength by the experiences of the war. Direct blood transfusion, on the other hand, Colonel CABOT thinks, would gain by more frequent use, the simple method practised in America being preferred. The permanent record of the Harvard Medical Unit is still to come, but whatever the value of the scientific work it contains, the contribution made by the unit to a friendly feeling and a sympathetic understanding between the two Armies will be no less permanent. The war has done much to draw the two English-speaking peoples together, and we warmly endorse Colonel CABOT'S expressed desire to make this *rapprochement* more intimate by the interchange of students, both before and after graduation, providing for the purpose a large scholarship fund available for promising students on either side of the water.

Annotations.

"Ne quid nimis."

WAR CURES.

MUCH stress has been put, and rightly, on war diseases. That way progress has lain. But there have also been war cures, and of these we have heard less. The disappearance of functional nervous disease among the civil population during the last four years is, however, a matter of general comment. In Berlin we understand that migraine disappeared completely from the month of August, 1914, and, without doubt, the work of general practitioners in this country has been mitigated by the fact that they have seen fewer minor ailments. Many of these, while real enough, are such as the patient communicates only to his or her (generally her) family doctor, and the particular family doctor has generally been away. Minor ailments cannot be assessed in actual figures, but there is a certain amount of evidence accumulating in regard to definite morbid conditions which have become numerically less frequent during the war. Dr. Herbert Elias and Dr. Richard Singer laid before the Vienna Medical Society on Oct. 18th last a therapeutic study¹ of the influence of war diet upon diabetes. Their conclusion is based upon figures, and it is a remarkable one. All degrees of diabetes as it occurred in Vienna were favourably influenced by the altered circumstances of war, in males almost without exception, in females frequently but by no means universally. The chart which we

reproduce here shows the decreasing number of diabetics dying in the Vienna General Hospital during the last five years, the thick line indicating total deaths, the interrupted line the deaths occurring in coma. The authors express regret that they cannot give the result in percentages, inasmuch as the total diabetic admissions to hospital could not be ascertained, but of the general lesson to be drawn from the chart there appears to be no doubt. The better war prognosis in males as distinguished from that in females is a fact claimed by these observers as a new observation, coinciding with their pre-war experience, for which they venture to advance no explanation. In the case of patients with slight glycosuria the difference between war and pre-war experience was very striking. Whereas not one of 29 slight diabetics before the war could be regarded as cured, 33 out of 39 became sugar-free under war conditions. The experience of Bouchardat during the siege of Paris in 1870-71 is quoted as having been similar. G. Klemperer, P. F. Richter, and others have noted the increased carbohydrate

tolerance, and have made similar observations in enemy countries during the present war. The cure of diabetes is perhaps of greater interest than the disappearance of obesity, of gout, and of chronic constipation noted during the same period and the increasing rarity of eclampsia in pregnant women. The balance is not equalised by the alleged increase in the frequency of peptic ulcer. Any observations of a similar character made in this country would be of interest and might throw useful light on the relation between habit and metabolic disorder.

BRONCHO-SPIROCHÆTOSIS.

THANKS to the work of G. A. Lurie,¹ Galli-Valerio,² and H. Violle,³ the subject of broncho-spirochætosis has received considerable light. The condition until recently was only of interest to the tropical practitioner, but lately it has become a serious matter to medical men in Europe, cases of the malady having been reported from Serbia and the Balkanic zone, Switzerland, and France. The condition and its etiological agent were first described in Ceylon in 1905 by Castellani, who later named the causal agent *Spirochæta bronchialis*. His researches were confirmed by S. Branch in 1907 in the West Indies, by Jackson in the same year in the Philippine Islands, and by several other observers, whilst H. G. Waters in 1909 recorded numerous cases from India. The condition was later found in practically every part of the tropics, of special importance being the work of Chalmers and O'Farrell, who succeeded in reproducing the disease in monkeys, and the thorough investigation of Fantham on the morphology of the organism. *Spirochæta bronchialis*, according to the description given by all these authors, is so markedly polymorphic that the suggestion arises whether the term does not cover more than one species or variety of spirochæte. The classical investigation of Fantham⁴ seems to prove, however, that the various forms found belong, in reality, to only one species, differing from the spirochætes occurring commonly in the mouth. Fantham discovered the coccoid stage of the parasite, which he believes to be of fundamental significance in the dissemination of the malady. Clinically, three types of the condition are to be distinguished—the acute, the subacute, and the chronic. The *acute type* develops abruptly; the patient complains of headache and rheumatoid pains all over the body; he feels chilly and coughs much, though there is but very scanty mucoid or muco-purulent expectoration. The fever generally lasts from 3-6 days. This influenza-like type of broncho-spirochætosis has given rise to a suggestion⁵ that true influenza may be a form of spirochætosis. The *subacute* and *chronic types* of broncho-spirochætosis are of practical relevance, as they may closely simulate pulmonary tuberculosis. In these types the patient often spits up blood, and this, together with wasting, an evening rise of temperature, and, on examination, the presence of patches of dullness and crepitations, may suggest a diagnosis of phthisis. In a certain number of cases, however, the general condition remains good. The first patient seen by Castellani in Ceylon in 1905 was still alive in 1915, and Violle quotes a number of cases in which the general

⁵ De Verbizier: Bull. Académie de Médecine, Séance 8 Octobre, 1918.

¹ Wiener klin. Wochenschr., Nov. 21st, 1918.

condition remained good throughout the course of the malady. The prognosis of broncho-spirochaetosis is, therefore, in most cases, good as far as life is concerned, but relapses seem to be extremely common, and cases of a malignant type, terminating fatally, have been placed on record.

As regards treatment most authors rely on arsenic, whilst others employ change of air, rest, and plenty of nourishing food. Galli-Valerio has used salvarsan with apparently good results. The whole subject deserves further investigation, especially in regard to the geographical distribution of the condition in the temperate zone, and the mode of infection. The practitioner should also be on his guard, as it is quite possible that a certain number of cases which, in the past, have been regarded as pulmonary tuberculosis, even though tubercle bacilli were constantly absent in the sputum, may have been cases of broncho-spirochaetosis.

LUNACY IN EGYPT.

We learn from the Report on Lunacy in Egypt for the year 1917 that the total number of admissions to asylums in that year was 1062, the largest on record. There are still only the two asylums in Egypt, one at Cairo, chiefly for the city dwellers, male and female, and the other at Khanka, where patients from the scattered districts are chiefly sent. The two groups of cases differ materially, general paralysis being common at Cairo but very rare at Khanka. Three different social classes are treated in the asylums, the paupers, those who contribute something towards their support, and the private paying patients. Voluntary boarders are still received. The patients we regret still to find in the parent institution are the criminal lunatics. The increase in the number of admissions is due chiefly to the fact that more patients are sent direct to the asylums and not detained in the local general hospitals; among them are a very large number of pellagrous insane. At both the asylums accommodation is inadequate, with the result that many partially cured patients are prematurely discharged to make room for the more acute cases, and frequently these patients break down again or add to the sum of criminal lunatics. The death-rate is very high in the two asylums, the total number of deaths during the year being 369, or 17.4 per cent. of the number resident. It should be noted, however, that many deaths occurred in patients who had only recently been admitted, due to the fact that they had been kept too long at home. A special hospital for military patients has been constructed out of the former assistant medical officer's house, to which during the year 126 cases were admitted, nearly every form of mental disorder being represented. The residence of these soldiers in the hospital was very short, and no accidents or deaths occurred. The admissions included a large number of adolescent cases, four general paralytics, and only two alcoholics; delusional cases were common, and melancholia occurred more frequently than mania. As to the apparent (or rather attributed) causes of insanity, congenital mental defect and general physical strain due to shell shock or to dysentery, or other debilitating causes, were recorded as common, and there were many relapses, but in the greater number the cause was mixed or doubtful. Turning to the medical superintendence of the asylums we call attention again to the work of Dr. John Warnock, C.M.G., and during his absence on active service of Dr. H. W. Dudgeon. Their

administration has been of the highest order, and praiseworthy effort is continually made to carry on scientific investigation; the State laboratory has assisted in the examination of the blood of 100 consecutive admissions, a positive Wassermann reaction being found in many other forms of mental disease than general paralysis of the insane. Blood and faeces were also examined in cases of bilharzia. In each report a table is given showing the number of criminal lunatics admitted, the nature of their crimes, and the form of their insanity. Eighty persons were thus received, namely 72 men and 8 women, and of these pellagrous insanity provided 12, hashish only 1, and G.P.I. 2. Next to pellagra, dementia is given as the most common form of insanity met with. In all there were 400 male criminal lunatics and 37 females. Attempts at murder were common, but theft was the most usual offence, the same applying to the pellagrous insane, while every form of antisocial crime was represented.

TETANUS WITHOUT TRISMUS.

THE enormous medical experience of the war has modified our knowledge of many diseases. Perhaps the most striking example is tetanus. It used to be taught that trismus was a characteristic early sign on which the diagnosis turned in cases of doubt. But the extensive prophylactic use of antitoxin in the wounds of war has produced new types of the disease in which old and well-established rules fail. We now know that the disease may be so mitigated that the spasms may be confined to the neighbourhood of the wound (local tetanus) and trismus or other spasm be completely absent. This form was known previously in experimental tetanus in animals. But the view of the pathology of tetanus brought forward by Professor H. H. Meyer and Dr. Fred Ransom (*THE LANCET*, Dec. 22nd, 1917, p. 929) that the increased irritability of the nerve centres is due to the passage of toxin up the motor nerves to the spinal cord, in which process the nerves of the infected area are at an advantage, would suggest that tetanus should always be local in onset, and, indeed it has been asserted that if cases are carefully watched from the beginning spasms of the muscles in the neighbourhood of the wound will always be observed. Not only is trismus absent in local tetanus, but, more remarkable, French observers have shown that it may be absent in general tetanus when modified by the prophylactic use of antitoxin. In the December number of the *Medical Review* is given the following case, recorded in the *Lyon Médical* by M. Roubier.

An Arab soldier was wounded in the left hand by a grenade on April 22nd, 1917. On the following day 20 c.cm. of tetanus antitoxin were injected, and eight days later 10 c.cm. On May 8th, when the wounds were healed and he was considered cured, the temperature rose to 102.6° F., and next morning to 105°. He sweated profusely and complained of pain in the neck and a little difficulty in swallowing. There was no trismus, and Kernig's sign was absent. Though the spleen was not enlarged malaria was suggested and quinine given. The temperature fell but rose again, and there were intense headache, slight dysphagia, and some stiffness of the neck. Kernig's sign and slight hyperaesthesia of the lower limbs were found. Blood examination was negative. On May 14th these symptoms persisted, and in certain regions a prick or even grazing of the skin produced local muscular contractions which were not painful. Lumbar puncture yielded normal fluid not under increased pressure. The contractions, which consisted of rapid twitches, not durable contractures, became more intense. On the 23rd the contractions were for the first time painful and there was contracture of the anterior muscles of the right thigh. It was increased on the slightest touch and paroxysms occurred spontaneously which were grafted on to the permanent hypertonia. Spontaneous twitches of the

sub-umbilical region occurred at variable intervals. Improvement began on June 7th and recovery followed. The treatment consisted in the administration of antitoxin and Baccelli's fluid. The absence of trismus rendered the diagnosis difficult. Malaria, septicæmia, and, on the appearance of the cervical rigidity, meningitis were in turn suggested.

Several French papers on tetanus without trismus have recently been published. Montais has shown that the classical form of tetanus which occurred at the beginning of the war became rarer as preventive serotherapy was more methodically applied. Lumière among 54 cases of tetanus after preventive injection found trismus absent in 15 and attenuated or late in appearing in 13. The explanation of the absence of trismus is not clear. A considerable immunity conferred by antitoxin would explain very well local tetanus or the late appearance of trismus as an initial symptom. But why should what are normally the most sensitive centres to the toxin become insensitive while other centres retain their sensitiveness?

HYSTERICAL VOMITING IN SOLDIERS.

THE war has given a great impetus to the study of functional nerve disease, and the literature of this subject promises to become a large and important one. The emotional stress and physical strain produced by the conditions of warfare are such as to provoke various neuroses, particularly in those predisposed to them. When these functional derangements are referred to the viscera their nature is likely to be overlooked. We published in THE LANCET of Jan. 4th an interesting paper on hysterical vomiting in soldiers by Captain W. R. Reynell. He points out that the hysterical nature of vomiting occurring in soldiers is liable to be overlooked and the condition thus often recorded and treated as if it resulted from some organic disturbance, such as gastritis. Captain Reynell gives a valuable definition of hysterical vomiting as "the perpetuation by suggestion of a symptom, due in the first place to a pathological condition such as that caused by gassing, dysentery, phthisis, or appendicitis." He states that gassing is the most frequent exciting cause of hysterical vomiting in soldiers, but he has observed that in a number of cases the vomiting is referred to an attack of dysentery, trench fever, or other infection. In either case the vomiting persists as an hysterical symptom long after the original exciting causes have ceased to be operative. In some cases the origin appears to be purely emotional. The vomiting may occur after every meal or only once or twice a day, while in mild cases there may be intervals of several days and the attacks of vomiting may be traced to emotional upset or to sudden excitement. The vomiting may be preceded by epigastric pain, which is relieved when the vomiting has occurred. It seems to be independent of diet in the majority of cases. There is an absence of any sign of organic disease, though wasting to the extent of the loss of several stones in weight may occur. The examination by X rays after a barium meal shows nothing abnormal and the stomach empties at the normal rate unless vomiting occurs. Captain Reynell states that the diagnosis is not usually difficult and depends upon the persistence of the vomiting in the absence of signs of organic disease, especially where there is a history of gassing or emotional stress. He points out the importance of recognising the hysterical nature of the condition owing to the fact that in a considerable proportion of cases the vomiting persists indefinitely in spite of dieting and treatment by medicines or by rectal

feeding, which tend rather to prolong than to cure it. The treatment recommended by Captain Reynell is to impress upon the patient the fact that his case has been thoroughly investigated, and then to explain the origin of the symptom and to indicate that it has now become converted into a habit. If necessary, a stomach-tube is passed before meals for its suggestive effect upon the patient. He is told that it is a method which does not fail, and that it will depend upon him how often the tube need be passed. Captain Reynell found that the vomiting usually ceased after a week or ten days, and that in patients of superior intelligence it is frequently possible for a cure to be effected by psycho-therapy without the passage of a tube. He adds a note to his paper expressing the opinion that hysterical vomiting is frequently overlooked in civil practice, and that many cases of chronic vomiting are hysterical in nature. He goes so far as to maintain that it is probable that most, if not all, cases of the pernicious vomiting of pregnancy are purely hysterical. While we should not be prepared to subscribe to this view without further evidence, Captain Reynell's paper is interesting and suggestive, and should lead to a more careful examination of cases of persistent vomiting of obscure causation in civil practice, in order to eliminate the possibility he suggests of hysterical persistence of vomiting, originally of organic causation, when the primary cause has ceased to be operative.

THE LESSONS OF THE LOUSE.

IN a primitive society feeble folk survive the dangers which beset them either by means of a shyness which withdraws them from taking risks or by a parasitism which claims the protection of something stronger. Like the coney, the louse is a feeble folk which, unlike it, has established its survival by an extreme intimacy with man, and in so doing has come to have a bearing on public health which is only now becoming generally appreciated. Mr. Ll. Lloyd, Lieutenant. R.A.M.C. (T.), whose experience as chief entomologist in Northern Rhodesia entitles him to speak with authority on zoological subjects, deals with this feeble parasite and its menace to mankind in a book,¹ intended avowedly for the general reader rather than for the specialist, the great merit of which is the statement of ascertained facts in a form bringing out the practical hygienic lessons to be drawn from them. Slow, short-lived, and defenceless, the louse has nevertheless been man's close companion from prehistoric times, for Mr. Lloyd considers the body-louse and the head-louse to be slightly divergent forms of a parent species infesting primitive man in his naked and hirsute state. At what stage in its history the louse became the intermediary of pathogenic spirochaetes and other organisms is not dealt with by Mr. Lloyd, but would form a very interesting chapter in the history of parasitism. We do not even know whether the louse itself is only the innocent medium of these noxious wares or whether as middleman it derives any personal benefit from the traffic. The first great hygienic lesson which emerges from a study of the facts is that the parasite must be regarded with respect. For untold ages the louse has been the object of shame and jest, but not of serious study, and this unfortunate symbiosis of ideas has been singularly successful in keeping up the still more unfor-

¹ *Lice and their Menace to Man.* By Ll. Lloyd, R.A.M.C. (T.) With a chapter on Trench Fever by Major W. Byam, R.A.M.C. Oxford Medical Publications. 1919. Pp. 136. Price 7s. 6d.

fortunate physical symbiosis essential to its life. Even Mr. Lloyd has a special repugnance for the crab-louse which he describes as an "abominable" insect. Bacteriologists do not brand even the *Pleiffer bacillus*. But surely applied knowledge cannot fail to deal with a feeble creature which lives for but 40 to 50 days, has little or no means of finding a new host, and soon dies of starvation when removed from the human skin on which its normal habit is to dine at least four or five times a day. The second lesson is that of thoroughness. Although so easy to kill, dying at a mere touch, on being dried or slightly warmed the failure of even drastic methods applied without system to extirpate it has resulted in a deeply-rooted notion that the louse arises spontaneously from the ground. Our soldiers in the South African War shared this belief with the Egyptians of Pharaoh's time, before whose eyes the dust became lice. But disinfection—as the phrase now runs—is only a question of thoroughness. In the Army at first only the man's shirt was disinfested, leaving his other garments as a safe refuge for the parasite. Then the whole clothing was treated, overlooking the hair, in which lice or nits still lurked. And, finally, the failure to deal simultaneously with the whole body of troops resulted in the ready re-infestation of the disinfested section by adjacent and still infested men. It was on the Eastern front that this lesson was most strikingly illustrated by Colonel W. Hunter's great achievement with the Stammers method, in which men's kits by the ten-thousand were sterilised by live steam in a special railway van.² The problem, Mr. Lloyd tells us, is a difficult one to solve under civilian conditions, but it is through the diffusion of the knowledge acquired under war conditions that the solution will come. The clear and concise knowledge imparted in this book should greatly help the civilian campaign against the louse. An illustrated poster just issued by the British Museum of Natural History at South Kensington at one half-penny, entitled "The Louse Danger," will help in the same direction.

A CONFERENCE ON THE TUBERCULOSIS SERVICE.

THE larger aspects of the tuberculosis question were just beginning to be seriously faced when the European upheaval put an end to all constructive labours. The position has been rendered vastly more urgent by the war, and public opinion has become less tolerant of delay. On the Tuberculosis Service of the country will rest a very heavy responsibility in the years ahead of us. The Tuberculosis Society foresees the need of strengthening the hands of those on whom the responsibility will fall and has arranged for a conference to be held at the house of the Royal Society of Medicine, 1, Wimpole-street, London, W., at 7 P.M. on Saturday, Jan. 25th, to discuss the status of the Tuberculosis Service under forthcoming legislation. Matters coming specially within the limits of the discussion are the scope of the tuberculosis officer's work, his relation to the present Public Health Service, his remuneration, security of tenure and superannuation; and it is hoped that the discussion may lead to a comprehensive and united policy for the control and eradication of tuberculosis, and be attended not only by tuberculosis officers, in the strict sense, but also by medical officers of sanatoriums, open-air schools, farm colonies, and tuber-

culosis hospitals. Resolutions to be submitted to the conference will be based upon the memorial passed by the Tuberculosis Society in 1914 and submitted at the time to members of the Government. The claims then made were that tuberculosis officers should be regarded as an independent service so far as their clinical duties are concerned, and be responsible for the management of institutions to which they are attached; that a satisfactory status and security of tenure should be secured for them; that the Tuberculosis Service should not count as a subsidiary branch of the Public Health Service; and that security of tenure and superannuation should be ensured for its members comparable to those ruling in the Lunacy and Prison Services. We trust that the conference will herald the development of the united policy which its promoters foreshadow.

PROPHYLACTIC MEASURES AGAINST INFLUENZA AT A PUBLIC SCHOOL.

THE responsibilities of those in charge of institutions, particularly public schools, at the present time are heavy, and any statistical results of prophylactic measures adopted must be welcome. We publish in our present issue an interesting note by Mr. G. E. Friend, medical officer of Christ's Hospital School, West Horsham, to which we may draw our readers' attention. After a small outbreak in the summer term, to which we will refer later, measures were taken to minimise the risks of infection as far as possible. The school being self-contained and enclosed by a ring fence, Mr. Friend advised the headmaster at the beginning of the winter term to stop all leave and keep the boys strictly within bounds—walks outside being allowed, but the town, 2½ miles away, and all houses off the school estate were put out of bounds. Segregation was, however, only possible to a limited extent, since visitors could not be kept away, and large numbers came twice a week, some of them staying over the week-end; nor could all leave of absence be stopped. Non-resident masters and servants were also possible sources of infection which could not be prevented. The time allowed for sleep had previously been increased by one hour and the amount of work and play reduced. The nasal drill described in THE LANCET of August 24th, 1918, by Dr. Isabel Ormiston was carried out twice daily. A polyvalent influenza vaccine, unmixed with other organisms, prepared by Dr. E. L. Hunt, was given to about 77 per cent. of the boys in a single dose—boys over 14 years of age receiving 70 million, those under this age 30 million. In all, 633 boys were inoculated, 306 receiving the larger dose, and 327 the smaller. Only 39 boys' parents objected to inoculation, but 128 boys were considered unsuitable, and 19 boys were absent, ill, so that 186 boys were not inoculated. Only one definite case of influenza occurred during the term, and the cases of medical illness were less than in any term since 1898. The one case was that of a boy—inoculated with 30 million of vaccine—who went home to attend the funeral of his mother who had died from influenza. He developed coryza and cough and slight fever, and apparently suffered from mild influenza. In addition there were 36 cases of "chill" of very mild character which clinically could not be regarded as influenza, and they were not examined bacteriologically. Inoculation was only carried out on Oct. 30th—i.e., at about half term—and 12 of the cases of "chill" occurred before this date. Of the 24 cases occurring after

² THE LANCET, Sept. 14th and 21st, 1918.

inoculation 7 were among the uninoculated—i.e., 4.2 per cent., and 17 among the inoculated—i.e., 2.6 per cent. From September onwards influenza was very prevalent in Horsham and in all the surrounding villages. About 18 cases, 3 of them complicated by pneumonia, occurred among the staff, and these were at once isolated. Mr. Friend attributes the gratifying freedom from influenza among the boys to physical training, nasal drill, an increase of the caloric value of the diet, and to the inoculation. To this we may add that prompt isolation of the cases occurring among the staff was also no doubt a valuable precaution. It is somewhat difficult to appraise the actual value of the inoculations owing to the absence of any outbreak of the disease among the boys from the success of the general measures adopted.

A small outbreak in the summer term mentioned by Mr. Friend is worth a brief reference. In the ten days previous to July 20th 21 cases of mild influenza occurred in various houses of the school. On the date just mentioned the cricket eleven went to Brighton to play a match. Next day five of the team were admitted to the infirmary, together with three other boys who were not in the team, but came from the same houses. Within the next four days 31 other cases were admitted, nearly all from the houses which had supplied the cricket team. Mr. Friend attributes this outbreak of 39 cases to the Brighton visit of the cricket team rather than to the 21 mild cases previously present. We do not feel quite convinced of the correctness of this explanation, since it involves a very short incubation period even for the five members of the cricket eleven, and an even shorter one for the three boys who were admitted to the infirmary on the same day, who must on this supposition have been infected by the five players during the early part of their incubation period. We may recall the interesting observations published by Major Michael G. Foster and Major H. Anstey Cookson in THE LANCET of Nov. 2nd, 1918, in which the incubation period of influenza seemed to be about 48 hours.

Sir David Bruce has been elected a Correspondent of the Académie des Sciences.

Sir Anthony Bowlby will deliver the Hunterian Oration at the Royal College of Surgeons of England on Friday, Feb. 14th, at 4 p.m.

AFTER having completed 20 years' service on the full staff of St. George's Hospital, according to the regulations, Sir Humphry Rolleston has ceased to be physician to the institution. But instead of automatically becoming consulting physician, which up to the present time has been the unbroken rule of the hospital, the house committee, on the recommendation of his colleagues, has appointed him emeritus physician for his lifetime, with the privilege of using the clinical material in the wards for teaching.

THE LANCET, VOL. II., 1918: THE INDEX.

THE Index and Title-page to the volume of THE LANCET which was completed with the issue of Dec. 28th, 1918, is now ready. Subscribers who bind up their numbers are requested to send a *post-card* (which is more convenient for filing purposes than a letter) to the Manager, THE LANCET Office, 423, Strand, London, W.C. 2, when a copy of the Index and Title-page will be supplied free of charge.

MEDICINE AND THE LAW.

The Irregular Sale of Poisons.

AT a recent inquest upon a police superintendent at Hemel Hempstead the evidence showed that the deceased, who had had to give up his position owing to his period of service having come to an end, had taken his life with prussic acid, and that he had been able to purchase the drug without complying with the regulations imposed by the Pharmacy Act. He had told the druggist who sold it to him that he wanted it in order to kill a dog, and the druggist, according to his own version of the transaction in the witness-box, had "presumed he would be all right in serving the police." The witness in question will no doubt have received a lesson which he will never forget, and in future will carry out to the letter any legal enactments which may affect his business. Probably he disregarded it in this instance because he thought that the local police superintendent was one who, of all others, would not be likely to make an improper use of his purchase, but he might have remembered that he was also the last person who should have tempted him into an irregularity such as he committed. The sale of dangerous drugs in contravention of the law which seeks to restrict and to supervise such transactions, no doubt, takes place not infrequently, and recent cases have shown that in relation to some drugs, after they have left the hands of the legitimate retailer, a substantial profit may be made by surreptitiously disposing of them. At another inquest, held at Isleworth, it was shown that the deceased, an elderly woman, experienced no difficulty in obtaining morphia from a firm of druggists in London by sending a succession of written orders, and that she received it in quantities of about 45 grains, one consignment lasting her for not more than three days. A prescription was mentioned as having been used by her, but particulars of it were not given. Her way of taking the drug was to moisten a finger with saliva, draw it across the packet of powder, and suck it. The medical officer of the infirmary in which the woman died ascribed death to valvular disease of the heart and congestion of the lungs, expressing at the same time an opinion that it had been accelerated by chronic morphia poisoning. The coroner observed that the druggist had been "very slack—to put it no higher."

Medical Practitioners and the Detection of Crime.

IT is to be hoped that the publicity given by the newspapers to the case of William Henry Gordon, described as an analytical chemist, with an address in Pall Mall, will be a useful lesson to druggists and others that the treatment of venereal diseases has been directly entrusted to the medical profession by the Venereal Diseases Act, 1917, and that in areas where that Act is in force there are heavy penalties provided for unqualified persons who attempt to administer such treatment. Gordon, it will be remembered, was recently sentenced by Mr. Denman at Marlborough-street police-court to pay a fine of £100 and £21 costs, or, in default, to undergo imprisonment for three months for having prescribed treatment and given advice to a member of the police force who was in good health and who had been sent to him for the purpose of detecting and convicting him. The sentence was well deserved, and Mr. Denman intimated that a more severe one would have been passed if another case mentioned had been proved before him, in which a person who had visited Gordon as a bona-fide patient was stated to have been treated by him as if for venereal disease, although, in fact, he was as free from it as was the police detective. The case upon which the conviction took place was, in short, a well-laid trap which will have had a desirable effect if it has procured the punishment of an offender, and if at the same time it serves as a warning to others. It has been, moreover, the result of action on the part of the National Council for Combating Venereal Diseases, whose late honorary medical secretary, Dr. Otto May, arranged the introduction of the police detective to Gordon, giving him a letter which he presented on his first visit to the defendant's office. In congratulating the National Council for Combating Venereal Diseases on its success we venture, however, to express a doubt as to the desirability of a member of the medical profession intervening directly in the detection of offenders in this or in other classes of criminal acts. We do

not question that Dr. Otto May, actuated by a sense of public duty, brought about with certainty a conviction which it was desirable to secure without failure through the omission of any detail. We are, nevertheless, of the opinion that medical men on such occasions are entirely within their proper sphere in giving necessary scientific evidence after qualifying themselves to do so by observation of the facts relevant for that purpose, and that by going further than this they travel out of that sphere without the justification that their action is necessary and indispensable. In other words, there are functions, such as acting when suitable the part of the *agent provocateur*, which rightly are performed by the police as everyday official duties and which are best left to them. If we were to hold as a matter of principle that a medical man should be willing, at the request of the police, to introduce a supposed patient to someone who in the name of medicine was likely to attempt a crime, one more step would take us to the point where such action would be looked upon as obligatory. The nature of the criminal offence is immaterial, but a parallel may be drawn between the treatment of venereal diseases and the more serious case of abortion. We can well imagine an occasion when a man suspected of procuring miscarriage in pregnant females might usefully be brought to justice by means of a sham subject employed by the police. Such a man might be a member of the medical profession, a regrettable black sheep whom many of his colleagues would gladly see brought to book. We should not, however, regard it as desirable that the actual bringing of the supposed pregnant woman into touch with the suspected person should be the work of a medical colleague. And yet the fact of the suspect being a medical man would not affect the question of his being a person whose detection was desirable, and in conceivable circumstances such an introduction of the supposed patient as we have suggested might be extremely effective in bring about that end. We prefer, nevertheless, to distinguish in such matters between the duties of those professionally entrusted with administering and enforcing the law, and duties which devolve upon medical men as citizens invited to assist in a limited degree in deference to their special qualifications for so doing.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Irish Medical Committee.

A MEETING of the Irish Medical Committee was held early in the month to discuss various matters affecting medical interests in Ireland. Mr. R. J. Johnstone, of Belfast, and Dr. Joseph Power, of Co. Tipperary, were re-elected chairman and vice-chairman respectively. Several grievances arising out of the working of the National Health Insurance Act were discussed, and the attention of the Commission was directed to be drawn again to the continued impropriety of permitting the Approved Societies to appoint the medical referees who are paid out of public funds. The Commission in 1915 pledged itself that it would retain all such appointments in its own hands. The opinion was expressed by the Committee that the remuneration for certification was, under present conditions, quite inadequate. The Committee considered the failure of many Poor-law unions to adopt graded scales of salaries for their medical officers, and decided to press the Local Government Board to use their powers to fix adequate salaries in the case of such unions. The probability of the Irish Government proceeding to introduce a Health Reform Bill for Ireland was also discussed by the Committee, and a watching committee was appointed to report any information that might be gained as to the intentions of the Government.

The Ministries of Health Bill.

All those who have the true interests of Ireland at heart were surprised to learn, on the introduction of the "Ministries of Health" Bill last session, that it did not apply to Ireland, and in a speech delivered in Belfast on Nov. 15th, 1918, Sir Edward Carson, M.P., said that as soon as he learned from Dr. Addison, M.P., that Ireland was to be excluded he put down immediately a resolution to move that the House of Commons refuse to go on with the Bill until Ireland was included. Ireland may have been excluded either on political or non-political grounds. In a medical journal I do not enter into controversial matters like politics,

further than to say that surely—even in a divided country like Ireland—people might agree on a question affecting their health, no matter what religious or political opinions they held. Yet what non-political reasons could be assigned for keeping Ireland out of a health measure, except that, owing to the backward state of public health in that country, it could not be treated simultaneously in the same way as England and Scotland? And so Ireland must have a measure for herself alone. For many reasons, in both Scotland and England, public health is half a century in advance of what it is in Ireland, where there are full-time officers of health only in the few county boroughs, while in the whole country there is not a county medical officer of health. There are no primary school boards, with the result that medical inspection of schools does not exist, and in the Insurance Act medical benefits in Ireland are conspicuous by their absence; while a Central Midwives Board was established in England in 1902 and in Scotland in 1915, the Irish Board came into existence only towards the end of 1918 and is not yet in full practical activity. If ever there was a country which needs a thorough reorganisation on modern lines of its public health conditions it is Ireland, and it is, therefore, to be hoped that when the new measure so much talked of at present—to co-ordinate health departments—is introduced, it will either include Ireland or give us a separate measure dealing with our country.

The Salaries of Dispensary Doctors.

The dispute between the dispensary medical officers and boards of guardians in reference to increase of salaries is rapidly approaching a crisis in the north of Ireland. At Derry the matter is still unsettled, and at Ballymena no action was taken on Jan. 4th, although a week later the guardians yielded to a threat of resignation. At Coleraine on Jan. 4th a letter from Dr. H. S. Morrison, secretary to the County Medical Committee, to the effect that he was instructed to say that the proposed scale of increase passed by the guardians was inadequate, making the initial salary £125 instead of £100, rising to £175 instead of £150, with special scale for the Coleraine Dispensary of £150 of initial salary, rising to £200, was marked read, and no satisfactory arrangement has been made. At Omagh the Local Government Board have sanctioned the increase of salaries of each of the medical officers of the union from £100 to £140 and the granting of three quinquennial increments of £10 each till a maximum of £170 is reached. The Belfast guardians are to consider the question of the request of their medical officers for an increase in their salaries at a special meeting.

Health of Belfast.

At the January meeting of the Belfast City Council, in seconding a resolution to the effect that the Infectious Disease Notification Act, 1889, shall apply in Belfast to the disease known as septic pneumonia (i.e., influenza), Mr. J. H. Stirling, a leading councillor, blamed the health authorities for taking no action until Dec. 7th last, and pointed out the admitted want of knowledge of the medical profession as to the nature of the epidemic or as to its real causation. It appears that the deaths for the four weeks ended Dec. 14th, 1918, were 863 from all causes, and of these 250 were attributed to chest affections. In reply, the chairman of the public health committee took the line that it was no part of the duty of the Belfast public health committee to set up a department of research to find out the cause of influenza, which, he declared, was entirely outside their jurisdiction. Their duty was to administer the law, and it was for the Universities or the Government to undertake research work. In other words, notwithstanding the fact that the Belfast City Council have a medical officer of health, a pathologist, a tuberculosis health officer, and numerous doctors (all paid) engaged at centres for child welfare, and with the rates of the city for public health work steadily rising, the whole business they are to do is, according to the chairman of the public health committee of the city of Belfast, to administer the law. Is it any wonder that in Belfast for 1918 we have a high general mortality rate and high rates for tuberculosis and infantile mortality? "To administer the law," says the chairman of the public health committee of the great city of Belfast, is all the duty that the health authority has to do. Let others bother themselves about the research work necessary to find out the cause and, as a natural corollary, the means of preventing and treating disease.

The War and After.

THE CASUALTY LIST.

FOR the first time for very many weeks past we have not to make any announcements of casualties amongst the members of the medical profession engaged in the war.

We are glad to learn from Dr. J. S. Martin, late Captain, R.A.M.C., of Leigh, Lancs, that he is not the Capt. J. S. Martin, R.A.M.C., who was officially reported to have died in the casualty list issued from the War Office on Friday, Jan. 3rd, and published in THE LANCET of Jan. 11th.

OBITUARY OF THE WAR.

JAMES THOMAS MCENTIRE, M.B., CH.B., D.P.H. DUB.,
MONS STAR; LÉGIION D'HONNEUR;
LIEUTENANT-COLONEL, ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel J. T. McEntire, who died of pneumonia following influenza at Salonika on Oct. 29th, was eldest son of the late Alexander Knox McEntire, J.P.,

B.L., official assignee in Ireland. Educated at St. Andrew's College, Dublin, he graduated at Trinity College and took the B.A. and M.B. degrees in 1902 and the D.P.H. in 1911. He joined the R.A.M.C. in 1903, and served in South Africa for five years and on the West Coast of Africa for two years. He went to France from Ireland in 1914 with the original expeditionary force and received the Mons Star. In recognition of his work in the early fighting, in which he was

often in positions of great danger, the French Government conferred on him the Legion of Honour after the first battle of Le Cateau. He was further mentioned in despatches on three occasions. In 1917, after a short rest at home, he was sent to Salonika in charge of the surgical division of a general hospital, and early this year was given command of a stationary hospital, with the acting rank of Lieut.-Colonel.

Colonel McEntire married Mary, daughter of the late James Little, of Dumfries, N.B., and leaves one daughter.

HENRY PARKS WHITWORTH, M.R.C.S. ENG.,
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain H. P. Whitworth, who died on Oct. 29th from wounds received 12 days previously, was second son of the late Wm. Whitworth, M.R.C.S. Eng., of St. Agnes, Cornwall. Educated at Epsom College and Guy's Hospital, where he played in the Rugby team during the seasons of 1912-13 and 1913-14, he qualified in 1914, taking the diplomas of the Conjoint Board, and then held several house appointments at his hospital. He joined the R.A.M.C. the same year and was posted to the 26th Field Ambulance. After being severely wounded during the first battle of the Somme in 1916 he

again went to France in 1918 and was attached to the 6th K.O.S.B. Whilst attending to his patients during the advance through Belgium he was wounded in the head and died in a casualty clearing station near Ypres.

GEORGE ELPHINSTONE KEITH, M.B., C.M. EDIN.,
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain G. E. Keith, who died in Italy of pneumonia following influenza on Dec. 6th last, at the age of 54 years, was youngest son of the late Dr. Thomas Keith of Edinburgh. Never robust, he spent a year on a ranch in Texas before graduating at Edinburgh in 1887. He held appointments in Edinburgh under the late Professor Annandale, and in the following year went to New York, where, after taking the M.D. degree at the Long Island College, Brooklyn, he became house surgeon at the Woman's Hospital, and there came in close contact with the leading gynaecologists of America. Before settling down in Manchester-square, London, where he devoted himself more especially to midwifery, he accompanied Lord Randolph Churchill when he went round the world in his vain search for health. He was part author of a text-book on abdominal surgery,

and for 10 or 12 years had devoted a large part of his time to the treatment of cancer by injection, the early account of the work being contained in "Cancer; Relief of Pain and Possible Cure." He joined the R.A.M.C. in July, 1915, and was promoted captain in 1916. Although over age, he served with the Expeditionary Force in France and Italy, and was one of the medical officers on the *Britannic* when she was torpedoed in the Aegean Sea. Captain Keith was unmarried.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualty among the sons of medical men is reported:—

Lieut.-Col. G. Buckston Browne, D.S.O., R.F.A., died of pneumonia, son of Mr. G. Buckston Browne, of Wimpole-street, London, W.

THE HONOURS LIST.

The following appointments of medical men to the Most Excellent Order of the British Empire for services in connexion with the war are announced:—

K.C.B.E.—E. N. Burnett, J.P., Chairman of the Economic Committee of the Army Medical Department, War Office; G. A. O'B. Reid; Col. W. H. White, R.A.M.C., Chairman and Consultant, Queen Mary's Royal Naval Hospital, Southend.

C.B.E.—H. H. Dale, F.R.S.; A. Elchholz, Senior Assistant Medical Officer, Board of Education; S. Lyle, Commissioner of Medical Services, Ministry of National Service; Col. W. G. Beyts, A.M.S., Assistant Director of Medical Service, Bombay Brigade; Lt.-Col. E. L. Ward, I.M.S., Inspector-General of Prisons, Punjab.

O.B.E.—A. M. Elliot, Headquarters Medical Examiner, British Red Cross Society; A. C. Ferguson, Commandant and Medical Officer, Thirsk Auxiliary Hospital, Yorkshire; J. T. Grey, Donor and Medical Officer, Stanmore House Auxiliary Hospital, Lenham; R. W. Johnstone, Commissioner of Medical Services, Ministry of National Service; J. R. Lunn, Commandant, "The Cecils" Auxiliary Hospital, Chappell Croft, Sussex; H. A. Macewen, Medical Inspector, Local Government Board; Capt. L. E. C. Norbury, Surgeon, British Red Cross Hospital, Netley; Maj. D. V. Rees, T.D., Operating Surgeon, Brecon and Bulthorpe Auxiliary Hospitals; C. Reid, Deputy County Director, Staffordshire Branch, British Red Cross Society; E. C. Roberts, J.P., Senior Medical Officer, Grovelands Auxiliary Hospital, Southgate Middlesex; Maj. C. S. de Segundo, V.D., Deputy Commissioner of Medical Services, Ministry of National Service; P. G. Selby, Medical Officer, Auxiliary Hospital, Sittingbourne, Kent; G. R. F. Stilwell, Medical Officer, Balgowan Auxiliary Hospital, Beckenham, Kent; G. M. Winter, J.P., Chairman, Torquay Food Control Committee; Lt.-Col. F. S. C. "Audi alteram partem."

ETIOLOGY OF LINGUAL CANCER.

To the Editor of THE LANCET.

SIR,—Your annotation on the above subject appearing in THE LANCET of Jan. 11th, in connexion with Mr. D'Arcy Power's Bradshaw lecture, is of the highest interest to the medical and general public, since it contains a grave warning, and prophesies a great increase in the disease unless measures are taken to deal adequately with the predisposing and exciting causes. Mr. Power concludes that syphilis cannot be considered more than the predisposing cause, and he suggests that the increased smoking prevalent in both sexes is the exciting cause.

As to Mr. Power's first conclusion, we know that even extremely severe types of gummatous tongue of long duration may not always develop into carcinoma; and as to tobacco being the exciting cause, as is pointed out, there must be at least another factor, at present unknown. Otherwise, why are not all excessive smokers (or at least a far larger proportion than is the case) also victims of the disease?

In discussing the etiology of lingual cancer it might be well to remember that with but few exceptions, notably that of new growths, affections of the tongue have hitherto been rightly regarded as merely symptomatic of general, or local, disease originating elsewhere, and that there is an intimate, though still obscure, relationship, anatomical and physiological, between the tongue and the stomach, or gastro-intestinal system, the state of the tongue—e.g., the presence of fur, dryness, moisture, swelling, &c.—being a useful index to the presence of various febrile or gastro-intestinal disturbances.

Further investigation may show that we have been mistaken in excluding from this list of diseases, arising from disturbances elsewhere, new growths of the tongue, which, after all, may prove to be due to some cause primarily affecting the stomach. Has the state of the gastric juice in lingual cancer been recorded? In investigating the etiology of lingual cancer, therefore, I urge a closer scrutiny of, and comparison with, the etiology of peptic ulcers, of which condition clinically I have had considerable experience.

We know from Dr. Charles Bolton's experiments that gastric ulcers can be produced by certain toxins, but do we know exactly how, in "atonic dyspepsia," the apparently analogous condition in the tongue, peptic ulceration, arises? Clinically, in my experience, this condition is especially associated with "starchy dyspepsia," an inability to digest certain starches (especially of potato, peas and beans, corn-flour, &c.), and with mental and emotional strains, overwork, and anxiety. Closely allied to this is the question of the "sore tongue" known to smokers, and hitherto generally attributed by them to the tobacco itself.

A prolonged consideration of the etiology of peptic ulcers of the tongue inclines me to think that though the acid and very strong tobacco used by the poorest classes can and does produce ulceration of the tongue, the ordinary and milder tobaccos smoked by the majority in pipe and cigarette are probably far less frequently the cause of the sore tongue occasionally experienced, and attributed to it, than is some other associated but less obvious condition—namely some slight gastric disturbance. Let me illustrate this by quoting an experience which must be familiar to most smokers dwelling in towns.

The late Marcus Beck, professor of surgery in University College, London, often used to remark that he suffered from a sore tongue if he smoked much in London, whereas, using the same tobacco, he could smoke all day, unaffected in this way, when holidaying and out on the moors all day. Here is a case where the same quality of tobacco produces different effects according to the smoker's general condition, which when poor more often than not manifests itself by a more faulty digestion than otherwise. With the relief of mental and physical strain the gastric metabolism is better and no sore tongue occurs.

Is it not reasonable, therefore, to consider that the sore tongue of smokers is essentially, or etiologically, to be henceforth regarded as a peptic ulcer due to overlooked or unsuspected, because perhaps mild, gastric disturbance occurring

in jaded town-dwellers? If so, perhaps in the sore tongue of smokers we may have a clue which may lead us to the discovery of the real cause of lingual cancer.

In conclusion, I suggest (1) that the trophic nerves governing gastro-intestinal metabolism, when exhausted by mental or emotional strain, give rise to the secretion of abnormal gastro-intestinal juices, which are unable to digest certain starchy foods, particularly potatoes, peas, and beans, and the absorption of the toxins arising from subsequent fermentation results in peptic ulcers of the tongue; (2) that the sore tongue of smokers (with the exception named previously) is due to associated mild gastric disturbance of the same kind; and (3) that these considerations as to the etiology of peptic ulcers may provide an important clue to the etiology of lingual cancer.

Even if my conclusions are shown to be unfounded, a discussion, focussing the experience of medical observers everywhere, cannot but be of the greatest assistance to future investigators.—I am, Sir, yours faithfully,

Harley-street, W., Jan. 12th, 1919. HENRY CURTIS, F.R.C.S.

CAUSES AND INCIDENCE OF DENTAL CARIES.

To the Editor of THE LANCET.

SIR,—Mr. R. Denison Pedley asks me to furnish some evidence of my statement "that there are among the inhabitants of this country more than 200 million carious teeth, as many alveolar abscesses (pyorrhœa alveolaris), and some 30 million root abscesses." Taking the population of the United Kingdom as 45 millions, this, according to my estimate, implies for each individual $4\frac{1}{2}$ carious teeth, $4\frac{1}{2}$ alveolar abscesses, and 2 root abscesses for every three persons. Does this estimate strike Mr. Pedley as excessive?

I have before me Dr. James Wheatley's 1914 report to the Education Committee of the Salop County Council, and an excellent report it is. Referring to his investigation into the prevalence of dental caries among elementary school children, he writes:—

"The figures have been in such close agreement each year that it appears certain that they may be taken as an accurate description of the amount of dental caries amongst the elementary school children of the county. The striking points are: (1) That only 3 per cent. of the children at age 12 and 5 per cent. at age 5 were free from caries; (2) that the average number of decayed teeth at the age of 5 was 6.8 and at the age of 12 was 4.8; (3) that out of 3794 children examined at the age of 5 no less than 1017 had ten or more decayed teeth, and out of 3580 children at 12.876, had seven or more decayed teeth."

When we come to examine adults we find that a considerable proportion of carious teeth have been extracted owing to the trouble they have caused, so that the number of carious teeth in a given mouth does not represent the number of permanent teeth which have become carious within it. Similarly, in regard to pyorrhœic alveoli, the number present does not take account of those which have closed up in consequence of extraction or spontaneous shedding of the teeth. The number of teeth spontaneously shed as the result of pyorrhœa is enormous, embracing as it probably does all those which are shed as the supposed result of senile decay. In other words, the edentulism of the aged is essentially pyorrhœic in origin.

In order to provide Mr. Pedley with figures I have hastily examined the teeth of 17 men, mostly discharged soldiers, occupying one of the wards of the West End Hospital for Diseases of the Nervous System. Their ages range from 21–43 years, and they come from various parts of England. I found the pyorrhœa average to be 9 (i.e., double my estimate), and the caries average to be 3 (i.e., one-third below my estimate).

Since pyorrhœa alveolaris is practically limited to adults, the average number of purulent alveoli in adults would need be considerably higher than $4\frac{1}{2}$ (as it actually is in the series examined), in order to bring the average of the total population up to this figure. The caries average in my series would have been much higher but for the large number of extractions—i.e., 9 per individual. Had no carious teeth been removed the average would have been 12 (i.e., more than double my estimate).

I have no statistics to give regarding root abscesses. I shall be surprised, however, if the estimate of two such abscesses for every three persons is regarded as excessive by dental surgeons. I am, Sir, yours faithfully,

Cavendish-square, W., Jan. 11th, 1919. HARRY CAMPBELL.

CAUSES AND INCIDENCE OF DENTAL CARIES.

To the Editor of THE LANCET.

SIR,—I am glad your columns are being used to emphasise the connexion between soft, sugary, or starchy food and decay of the teeth. School clinics are doing much to cure and prevent caries at school age, but why should it be allowed to occur at all? Nature shows that the young animal should pass from its mother's milk to hard food, which keeps the teeth clean and exercises the jaws, and that with such diet animals rarely get caries. Museums show that caries is exceptional in uncivilised man. Yet our mothers are still, with medical approbation, encouraged to feed their babies as the teeth emerge on soft, sweet food, with its inevitable consequences of contracted jaws and decaying teeth.

Dr. Sim Wallace has shown that caries may be largely prevented without altogether imitating Nature if every meal is completed with a detergent food. If it is not practicable to revert to a diet which will produce a larger jaw and better developed teeth we may at least follow Dr. Wallace's teaching sufficiently to greatly diminish the occurrence of caries with all the suffering and ill-health which go along with it. The matter is largely in the hands of the medical practitioner.

I am, Sir, yours faithfully,

Woolwich, Jan. 8th, 1919.

SIDNEY DAVIES.

AUTOTHERAPY OR BLEEDING.

To the Editor of THE LANCET.

SIR,—A new line of treatment is suggested in the annotation in THE LANCET of Dec. 28th, 1918, p. 889, on Dr. Luigi Meille's method of treating influenza by subcutaneous injection of the patient's serum, presumably containing antitoxins. Having tried this practice without beneficial results in another disease, I beg leave to record a negative observation. Two years ago, assuming that opsonins are free in serum, I withdrew 50 c.cm. of blood from a tuberculous patient showing severe intermittent pyrexia. Blood was run direct from the median basilic vein into a sterile flask and left to coagulate for 24 hours. Most of the serum was recovered and injected into the patient's groin. This was done twice with an interval of ten days. After withdrawing the blood there was a transient fall in temperature and in pulse-rate, but as the actual injection of serum had no influence on the disease, and as blood-letting is generally contra-indicated in pulmonary tuberculosis, the practice was abandoned.

May I also suggest that Dr. Meille's results were possibly due to the bleeding and not to the serum, and that the practice of bleeding, so universal in the past, may have some advantages over our indirect modern methods of reducing engorgement of arteries or veins. Until the middle of last century even healthy adults were regularly bled, and, according to Sir James Paget, "not one of these persons suffered harm." Again, Sir Thomas Watson considered venesection to be "a potent and life-preserving remedy" in many diseases. According to Quain, blood-letting in the early stages of pneumonia "relieves pain, abates fever, and, if it does not arrest the disease, it certainly appears to lessen its duration." Curiously enough, this author states that physicians first learnt that blood-letting was not a universal panacea during the influenza epidemic of 1830.

I am, Sir, yours faithfully,

London, Dec. 29th, 1918.

HALLIDAY SUTHERLAND.

PURULENT BRONCHO-PNEUMONIA ASSOCIATED WITH THE MENINGOCOCCUS.

To the Editor of THE LANCET.

SIR,—In your issue of Jan. 11th "Bacteriologist" deals somewhat harshly with a short description I gave in THE LANCET of Dec. 28th, 1918, of "Six Cases of Purulent Broncho-pneumonia Associated with the Meningococcus." He states that this title is "wholly misleading," although I purposely used the words "associated with." Apparently he considers them synonymous with "caused by" or "due to." When, after summarising the facts, I gave what appeared to me the probabilities, I was most careful to commence by saying it was only my opinion. I make no

pretence to "bacteriological proof," nor is this to be wondered at, seeing that three of the six patients were dead and the other three entirely convalescent at least a fortnight before I heard of them.

I published the notes because the series of cases, and their sequel in the occurrence of a case of cerebro-spinal fever, appeared to me so suggestive in the light of other reports, not yet published, as to be quite worth recording. That the meningococcus does cause pneumonia in certain cases is believed by many,¹ but this little series of cases which I have been able so imperfectly to investigate becomes especially interesting if viewed in the light of information derived from such an outbreak as that at Colmar in January, 1906, which is fully described by Jacobitz.² The outbreak occurred in one company of a Jäger Battalion. Twelve patients (other than carriers) were proved to be infected by the meningococcus, and Jacobitz divides his 12 cases into five groups, thus:—

1. Two cases showing typical cerebro-spinal meningitis without complications.
2. Three cases showing meningococcus pneumonia in association with meningitis.
3. One case of pneumonia without meningitis. The symptoms included pyrexia ending by crisis, rusty sputum, and signs of consolidation. Microscopic examination of the sputum showed only Gram-negative intracellular cocci, which were cultivated and identified as meningococci by agglutination. Meningococci were also present in the naso-pharynx, but pneumococci were never observed in the sputum in this case.
4. Four cases of bronchial catarrh without meningitis. These patients were only moderately ill, but the sputum showed numerous meningococci, which were cultivated and proved by agglutination. All had meningococci also in the naso-pharynx.
5. Two cases of lung infection in which the meningococcus was found mixed with other bacteria.

Referring to my own series, may I add that none of the three convalescents have proved chronic carriers, although when first examined they all showed almost pure and very abundant cultures. This disposes of the explanation that coincidence had brought together three chronic carriers of Type I. One of "Bacteriologist's" criticisms is just, I should not have mentioned Pfeiffer's bacillus.

I am, Sir, yours faithfully,

J. A. GLOVER,

Jan. 13th, 1919.

Captain, R.A.M.C.

* * Dr. Glover will be interested to read a short paper by Dr. William Fletcher, published in this issue.—Ed. L.

CROOKES'S LENSES.

To the Editor of THE LANCET.

SIR,—May I ask any of your readers to be so kind as to explain what are the special benefits which accrue to the use of Crookes's tinted lenses? Does their light-yellow tint merely cut off from the eye a small portion of the red and violet rays which go to make up white light? and, if so, would not any glasses of the same tint have the same effect? Or have they by their composition other properties than these, and, if so, what are they, and what is the construction of the glass which gives them these properties?

I am, Sir, yours faithfully,

Jan. 11th, 1919.

ENQUIRER.

* * In consequence of the prevalence of cataract amongst glass bottle makers researches were undertaken by Sir William Crookes some years ago into the possibility of obtaining glass opaque to the noxious ultra-violet and ultra-red rays and still transparent to light. In the course of his experiments a large number of metals were used, salts of which were incorporated in the experimental glasses, over 300 varieties being prepared. While none of them fulfilled the above conditions with perfection, some of them did very nearly, and the "No. 1" Crookes glass which is now supplied by opticians, while being practically completely transparent to light, does effectually cut off a very high percentage of both heat and actinic rays, and in this respect is superior to ordinary amber or smoked glass for cases in which it is desirable to protect the eyes from these rays without interfering with vision. Opticians also supply a "No. 2" Crookes glass which is partially opaque to light, suitable to be employed only in those cases where the amount of visible light is excessive. Sir William Crookes's own report on his experiments will be found in the Philosophical Transactions of the Royal Society for 1913.—Ed. L.

THE LATE HENRY SANDFORD.

To the Editor of THE LANCET.

SIR,—I have read with great regret your announcement of Mr. Henry Sandford's death. He was, I believe, the last survivor of those connected with THE LANCET, in any capacity, when I joined the staff 47 years ago. Mr. Potter, his senior partner, was then in the full vigour of bodily and mental health, but whenever he was unable to attend at THE LANCET Office "young Sandford," as he was then called, used to take his place.

By a melancholy coincidence Dr. Thomas Buzzard died a few days later than Mr. Sandford. With him passed away the last of the literary and editorial staff existing when I joined. At that time there were, in addition to Dr. James Wakley, Tilbury Fox (who acted as editor during Dr. James Wakley's illness), J. P. Steele, Brudenell Carter, James Grey Glover, Christopher Heath, Anstie, Henry Power, Jeffrey Marston, Harry Leach, Stallard, John Netten Radcliffe, Vivian Poore, and others whom at the moment I cannot recall. Thomas Henry Wakley, F.R.C.S., eldest son of the Founder of the paper, was at that time in charge of the business side of the journal. All these and a few others were, I remember, at the Jubilee Dinner of THE LANCET in 1873.

It is with pleasure I notice the continued vitality and prosperity of THE LANCET.

Wishing you a happy and prosperous new year,

I am, Sir, yours faithfully,

Harley-street, W., Jan. 6th, 1919.

JOHN TWEEDY.

Obituary.

WILLIAM ASHTON ELLIS, M.R.C.S. ENG.

Mr. W. A. Ellis, who died on Jan. 2nd, aged 66 years, was son of the late Robert Ellis, M.R.C.S., of London. Educated at Westminster (1865-1870), where he won a Queen's scholarship in 1867, he entered St. George's Hospital in 1871, took the M.R.C.S. in 1876, and the L.R.C.P. in 1878. He is chiefly to be remembered as a Wagnerian scholar; for some years he edited *The Meister* (quarterly journal of the Wagnerian Society), and he was the author of "Richard Wagner's Prose Works," in eight volumes, and of a life of Wagner in six volumes. Soon after qualification he had acted as resident medical officer to the Western Dispensary, and during the war he had resumed his old post there. Mr. Ellis was formerly honorary secretary of the Association of Members of the Royal College of Surgeons of England, and during the latter years of the last century he was a prolific writer on the subject of reform of that body.

LAWRENCE HENRY BENNETT, M.A., M.B. OXON., M.R.C.S. ENG.

Mr. L. H. Bennett, who died suddenly on Dec. 28th at Paignton, was third son of Henry Bennett, of Westminster, Glos. Educated at Clifton (1877-80), he matriculated at Trinity College, Oxford, in 1880, at the age of 18. He took his B.A. degree in 1884, and entered at St. George's Hospital the same year, obtaining the qualification of the Conjoint Board in 1889 and taking the M.A., M.B., B.Ch. Oxon. in 1890. After serving as ophthalmic assistant and orthopaedic assistant at St. George's Hospital he settled in practice at East Ilsley, near Newbury, Berks, and later moved to Paignton, where he had an extensive practice.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

SUBSCRIPTIONS TO THE SECOND APPEAL.

The following subscriptions have been received up to Monday, Jan. 13th:—

| | £ s. d. | | £ s. d. |
|-----------------------|---------|-----------------------|---------|
| Mr. E. Spencer Evans | | Mr. J. F. Cownie | 1 1 0 |
| (monthly) | 0 10 0 | Dr. C. Buttar | 3 3 0 |
| American Red Cross | | Dr. Vincent S. Hodson | 1 1 0 |
| Commission for | | Dr. E. S. Green | 1 1 0 |
| Belgium (monthly) ... | 200 0 0 | | |

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W. 1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

Major (acting Lieut.-Col.) E. A. Davidson to be acting Colonel whilst employed as an Assistant Director of Medical Services of a Division.

Major C. W. O'Brien relinquishes the acting rank of Lieutenant-Colonel on re-posting.

Major (acting Lieut.-Col.) H. F. Shea to be acting Colonel whilst specially employed.

Temp. Major C. H. G. Ramsbottom to be acting Lieutenant-Colonel whilst specially employed.

Capt. (acting Major) J. W. Bennett to be acting Lieutenant-Colonel whilst specially employed.

Temp. Capt. (acting Major) W. Kennedy-Taylor to be acting Lieutenant-Colonel whilst in charge of Guildford War Hospital.

Major C. P. Thomson is placed on the half-pay list.

To be acting Majors: Capt. R. A. Austin, D. W. Beamish, C. McQueen; Temp. Capt. R. Bruce Low, A. S. Wakely, A. G. M. Middleton, O. K. L. Wilson, J. R. Anderson, J. G. Moseley, H. J. de Brent, T. B. Amyot, J. McDonnell, A. R. Esler, W. L. Cassels.

Temporary Captains to be acting Majors whilst specially employed: S. B. Martin, J. C. Muir, F. R. Barwell.

Temp. Capt. J. Anderson, L. F. Hemmans, F. G. Bell relinquish the acting rank of Major on re-posting.

Temp. Lieut. T. A. Matthews and N. J. Newbould to be temporary Captains.

D. O. Parmenter to be temporary Honorary Lieutenant whilst serving with No. 22 General Hospital (Harvard Unit).

Canadian Army Medical Corps.

Temp. Capt. (acting Major) M. H. Allen to retain the acting rank of Major whilst employed in D.G.M.S. Office.

Hon. Capt. (acting Hon. Major) A. E. Clifton, D.C.M., to retain the acting rank of Honorary Major whilst employed as Inspector of Technical Equipment in D.G.M.S. Office.

Temp. Hon. Capt. J. W. White relinquishes the acting honorary rank of Major on ceasing to command a Depot.

SPECIAL RESERVE OF OFFICERS.

Capt. P. Walsh relinquishes the acting rank of Major on re-posting.

Captains to be acting Majors: S. K. Young, W. O. Tobias. Whilst specially employed: A. J. Brown, W. O. Mackie.

W. Oats to be Lieutenant.

TERRITORIAL FORCE.

Major (acting Lieut.-Col.) J. B. Yeoman relinquishes acting rank on ceasing to be specially employed.

Major W. R. E. Williams relinquishes his commission on account of ill-health.

Captains to be acting Majors whilst specially employed: R. E. Pitts, J. W. Wood, W. L. Cockroft, A. C. Tibbitts.

Capt. (acting Major) G. S. Williamson relinquishes his acting rank on ceasing to be specially employed.

Capt. L. E. H. K. Barker relinquishes his commission on account of ill-health contracted on active service.

Major A. M. H. Gray, Capt. A. E. Webb-Johnson, W. J. Wilson (Lt. Major), G. A. Williamson, Lieut. F. J. Cleminson (temp. Capt.) (retains his temporary rank) are transferred from the List of Officers Supernumerary for service with the Officers Training Corps.

Officers seconded for service with the R.A.F.: Major J. W. Keay, Capt. J. E. Dunbar, V. T. Ellwood, A. D. Kennedy, J. E. Lascelles.

1st Southern General Hospital.—Major W. Kirkpatrick to be acting Lieutenant-Colonel whilst specially employed, and to be seconded.

5th Northern General Hospital.—Capt. J. W. Patrick is restored to the establishment.

2nd London Sanitary Company.—Capt. (acting Major) F. S. Carson relinquishes his acting rank on ceasing to be specially employed.

1st Northern General Hospital.—Major (acting Lieut.-Col.) G. Hall, C.M.G., relinquishes his acting rank on ceasing to be specially employed.

1st Eastern General Hospital.—Capt. (acting Major) R. V. Slattery relinquishes his acting rank on ceasing to be specially employed, and remains seconded.

3rd Southern General Hospital.—Capt. W. B. Secretan is seconded for duty with the Reading War Hospital.

4th London General Hospital.—Lieut.-Col. Sir N. I. C. Tirard is retired on attaining the age limit, and retains the rank of Lieutenant-Colonel.

Major (Brevet Lieut.-Col.) Smart, from 1st Scottish General Hospital, to be Lieutenant-Colonel on the permanent personnel.

TERRITORIAL FORCE RESERVE.

Capt. E. S. Stork, D.S.O., from Attached to Units other than Medical Units, to be Captain.

Capt. P. C. Mitchell relinquishes his commission on ceasing to be employed, and retains the rank of Captain.

Lieut. G. T. Nichols and C. W. Stewart relinquish their commissions on ceasing to be employed, and retain the rank of Lieutenant.

ROYAL AIR FORCE.

C. G. Galpin (temp. Capt., ret. pay) is granted a temporary honorary commission as Major.

Capt. G. Fehrsen relinquishes his commission on ceasing to be employed, and retains his rank.

DEATHS IN THE SERVICES.

Surgeon-General Sir James Howard Thornton, on Jan. 6th, aged 85. He entered the I.M.S. in which his father was a major, in 1868, and the two served throughout the Indian Mutiny. The son then went to China, and was later wounded in action in the Khasia and Jyntia Hills campaign. He was chief medical officer in the Suakin and Hargara expeditions. He was five times mentioned in despatches, received four medals with seven clasps, the Khedive's star, the C.B., and was finally created K.C.B. in 1904. He retired in 1891 to settle at Hove, where he became a magistrate and a valued member of the town council.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.1.

Monday, Jan. 20th.

GENERAL MEETING OF FELLOWS: at 5 P.M.

Lecture:

Lieut.-Colonel Sir James Barrett, R.A.M.C.: The Management of Venereal Diseases in Egypt during the War (with illustrations).

Tuesday, Jan. 21st.

GENERAL MEETING OF FELLOWS: at 5 P.M.

Ballot for Election to the Fellowship. (Names already circulated.)

Thursday, Jan. 23rd.

GENERAL MEETING OF FELLOWS, at 5 P.M.

Discussion:

On "Shock," opened by Professor Bayliss, F.R.S., and Dr. Dale, F.R.S.

MEETINGS OF SECTIONS.

Wednesday, Jan. 22nd.

SURGERY (Hon. Secretaries—Y. Warren Low, Cyril A. E. Nitch): at 5.30 P.M.

Paper:

Major C. W. Waldron, O.A.M.C., and Captain E. F. Risdon, O.A.M.C.: Mandibular Bone Grafts.

To be followed by a Discussion on "Bone Grafting." Speakers:—Captain W. E. Galie, O.A.M.C., Major Naughton Dunn, R.A.M.C., Major Alwyn Smith, D.S.O., R.A.M.C., Major Robert Milne, R.A.M.C.

Cases will be shown at 5 P.M.

Friday, Jan. 24th.

STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—G. E. C. Pritchard, H. O. Cameron, C. P. Lepage): at 5 P.M.

Cases:

Dr. F. J. Poynton: (1) Myoclonia Multiplex in a Girl aged 2½ years; (2) Pseudo-hypertrophic Muscular Paralysis.

Discussion:

The Etiology, Prevention, and Non-operative Treatment of "Adenoids," opened by Dr. Harry Campbell and Dr. Edmund Cantley.

Those wishing to take part in the Discussion are requested to forward their names to the Senior Hon. Secretary.

The Royal Society of Medicine keeps open house for R.A.M.C. men and M.O.'s of the Dominions and Allies. The principal hospitals in the metropolis admit medical officers to their operations, lectures, &c. Particulars on application to the Secretary at 1, Wimpole-street, London, W.1.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

Six Hunterian Lectures on Phases in the Life and Work of John Hunter. The Lectures will be illustrated by Hunterian Preparations, Drawings, and Records:—

MONDAY, Jan. 20th.—5 P.M., Lecture I.—Prof. A. Keith: The Cradle of the Hunterian School.

WEDNESDAY—5 P.M., Lecture II.—Prof. A. Keith: The Rise and Decline of the Hunterian School in London.

FRIDAY—5 P.M., Lecture III.—Prof. A. Keith: The Time, Place, and Circumstance of John Hunter's Career in London.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

Clinics each week-day at 2 P.M., Wednesday, Friday and Saturday also at 10 A.M.

(Details of Post-Graduate Course were given in issue of Nov. 30th, 1918.)

ROYAL INSTITUTE OF PUBLIC HEALTH, in the Lecture Hall of the Institute, 37, Russell-square, W.C.

Course of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—

WEDNESDAY, Jan. 22nd.—4 P.M., Prof. I. W. Hall: Industrial Hygiene in Relation to War Strain and Technical Development.

Medical News.

UNIVERSITY OF LIVERPOOL.—The following have passed the January examination for the Diploma in Public Health: Shaikh Ghulam Mohamed, M.B., Ch.B., and Peter Paul Wright, M.B., B.Ch., B.A.O.

A SCHEME for establishing a chair of Mental Diseases at Edinburgh University has been approved by the University Court. The board of the Royal Edinburgh Asylum for the Insane has made the foundation possible by offering an endowment of £10,000.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A quarterly meeting of the Council was held on Jan. 9th, Sir George Makins, the President, being in the chair.—It was resolved to accord a vote of congratulation to Sir John Lynn Thomas on being made a Knight of the British Empire.—In accordance with the recommendation of the Museum Committee, it was resolved that the skeleton of the Greenland whale be taken down and placed in a room in the basement.—The best thanks of the Council were given to Mr. Alban Doran for presenting to the library five volumes of his literary contributions, together with five other volumes of pamphlets and articles mainly on anatomical

and gynaecological subjects.—The secretary reported that one dissertation on "Injuries and Diseases of the Pancreas and their Treatment," the Jacksonian prize-subject for 1918, had been received.—It was resolved that in pursuance of the action taken by the Council in 1915 the President be requested to represent to His Majesty's Government that in any legislation relating to the promotion of the public health provision should be made for ensuring an adequate supply of material for the anatomical and surgical instruction of students and practitioners of medicine.

URBAN VITAL STATISTICS.

(Week ended Jan. 11th, 1919.)

English and Welsh Towns.—In the 98 English and Welsh towns, with an aggregate civil population estimated at 18,500,000 persons, the annual rate of mortality was 16.0, against 14.8 and 16.1 per 1000 in the two preceding weeks. In London, with a population slightly exceeding 4,000,000 persons, the annual death-rate was 15.8, or 0.8 per 1000 below that recorded in the previous week; among the remaining towns the rates ranged from 7.9 in Walthamstow, 8.2 in Hornsey, and 8.3 in Ilford, to 22.7 in West Hartlepool, 23.7 in Hastings, and 27.3 in Liverpool. The principal epidemic diseases caused 164 deaths, which corresponded to an annual rate of 0.5 per 1000, and included 64 from diphtheria, 46 from infantile diarrhoea, 17 each from measles and whooping-cough, 15 from scarlet fever, and 5 from enteric fever. The deaths from influenza, which had steadily declined from 7559 to 441 in the nine preceding weeks, further fell to 380, and included 68 in London, 56 in Liverpool, 19 in Birmingham, 18 in Manchester, and 14 each in Bristol and Leeds. There were 5 cases of small-pox, 1058 of scarlet fever, and 1139 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital; against 3, 1062, and 1116 respectively at the end of the previous week. The causes of 52 deaths in the 98 towns were uncertified, of which 10 were registered in Liverpool, 8 in Birmingham, 5 in London, and 3 each in Manchester, Gateshead, and Tynemouth.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality, which had increased from 14.8 to 16.7 per 1000 in the three preceding weeks, further rose to 18.6 per 1000. The 399 deaths in Glasgow corresponded to an annual rate of 18.6 per 1000, and included 9 from whooping-cough, 5 from infantile diarrhoea, 3 from diphtheria, 2 from scarlet fever, and 1 from enteric fever. The 122 deaths in Edinburgh were equal to a rate of 18.9 per 1000, and included 11 from whooping-cough and 2 from diphtheria.

Irish Towns.—The 165 deaths in Dublin corresponded to an annual rate of 21.2, or 2.2 per 1000 below that recorded in the previous week, and included 2 from infantile diarrhoea. The 157 deaths in Belfast were equal to a rate of 20.4 per 1000, and included 2 from infantile diarrhoea and 1 from measles.

Communications, Letters, &c., to the Editor have been received from—

A.—Col. J. G. Adams, A.D.M.S.
B.—Dr. H. Brown, Lond.; Messrs. John Bell, Hills, and Lucas, Lond.; Dr. F. J. C. Blackmore, Lond.
C.—Dr. H. Campbell, Lond.; Col. S. L. Cummins, A.M.S.; Capt. J. Campbell, R.A.M.C.(S.R.); Mr. H. G. H. Clarkson, Birtwith; Dr. O. Coombs, Clifton; Dr. A. Cox, Lond.; Dr. S. Cheiliah, Colombo; Chicago School of Sanitary Instruction; Dr. J. A. Calantar, Lond.; Dr. C. M. Craig, Abergeldy; Dr. B. L. Collins, Lond.; Dr. R. Craig, Lond.; Dr. D. E. Core, Lond.; Mr. H. Curtis, Lond.; Mr. J. Cabburn, Lond.

Appointments.

ALLEN, V. F., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Swaffham District of Norfolk.
 CLEGG, S. J., M.D. Manoh., Deputy Medical Officer of Health for Newcastle.
 HACKETT, J. A. W., M.B., Ch.B. Edin., reappointed Medical Officer for the Gainsborough Urban District.
 HALL, ROBERT, L.R.C.P. Ed., L.R.C.S. & L.M. Ed., Examiner in Clinical Medicine in Belfast University, and Consulting Physician to the Ulster Volunteer Force Hospital for Discharged Sailors and Soldiers, Belfast (under Ministry of Pensions).
 HARGREAVE, W., M.B. Lond., and STEPHENSON, G. E., Captain, R.A.M.C., Police Surgeons for Newcastle.
 ROSS, D. M., M.B., Ch.B. Edin., Physician Superintendent, James Murray's Royal Asylum, Perth.
 SHARPLEY, J. E., M.R.C.S., L.R.C.P. Lond., reappointed District Medical Officer of the Blyborough District, Gainsborough Union.

Vacancies.

For further information refer to the advertisement columns.

Birkenhead Borough Hospital.—Jun. H.S. £170.
 Birmingham General Dispensary.—Tuber. Officer. £800.
 Birmingham General Hospital.—Vacancies on Res. Staff.
 Bradford Royal Eye and Ear Hospital.—Ophth. S.
 Chichester, Royal West Sussex Hospital.—H.S. £180.
 Croydon County Borough (Ante-Natal Clinic).—Female Med. Prac. £1 ls. per session.
 Dorchester, Dorset County Asylum.—Second Asst. M.O. £300.
 Dorset County Council.—Temp. Asst. M.O.H. £400.
 East London Hospital for Children and Dispensary for Women, Shadwell, E.—Asst. Res. M.O. £125. Also Casualty Officer. £120.
 Eccles and Paritcroft Hospital, near Manchester.—Res. H.S. £250.
 Edinburgh, Venereal Diseases Scheme.—Female Asst. M.O. £400.
 Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—Female Temp. Asst. S.
 Exeter City Mental Hospital, Digby, near Exeter.—Asst. M.O. £300.
 Hellingly, East Sussex County Asylum.—Temp. Asst. M.O. 7 gs. per wk.
 Hull City Education Committee.—Asst. Female School M.O. £400.
 Manchester, Ancoats Hospital, Mill-street.—Hon. P.
 Monmouthshire County Council.—Female Asst. M.O. £400.
 North Edding Asylum.—Locum Tenens M.O. 7 gs. per week.
 Northampton County Borough.—Temp. Tuber. Officer. £400.
 Painsley Hospital, Lower Common, S.W.—Res. M.O. £150.
 Rochester, St. Bartholomew's Hospital.—Clin. Asst. £150.
 Royal Free Hospital, Gray's Inn-road, W.C.—H.P. £250. Casualty H.S. £100.
 Swindon Borough.—Asst. M.O.H. £500.
 Taunton, Taunton and Somerset Hospital.—Sen. H.S. £250.
 University of London.—Examiners.
 Victoria Hospital for Children, Tite-street, Chelsea, S.W.—H.P. and H.S. £200.
 Western Ophthalmic Hospital, Marylebone-road, N.W.—Vacancies on Medical Staff.
 Westmorland Sanatorium, Meathop, Grange-over-Sands.—Sen. Asst. M.O. and Asst. Tuber. Officer. £350.
 Whitehaven and West Cumberland Infirmary.—Res. H.S. £150 to £180.
 The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Alford, Aberdeen; Heckington, Lincoln; and Ilminster, Somerset.

Births, Marriages, and Deaths.

BIRTHS.

ALTOUNYAN.—On Jan. 8th, at Hampstead, the wife of Captain E. H. R. Altounyan, R.A.M.C., of a daughter.
 CORFIELD.—On Jan. 12th, at Pembroke-road, Clifton, Bristol, the wife of Captain Charles Corfield, R.A.M.C. (T.F.), of a daughter.
 FAIRBAIRN.—On Jan. 8th, at Blackpool, the wife of Major J. Fairbairn, M.B., R.A.M.C., of a daughter.
 WILLIAMS.—On Jan. 8th, at Greystones, Canford Cliffs, Bournemouth, the wife of Dr. C. Campbell Williams, of a son.

MARRIAGES.

BLISS—COOPER.—On Jan. 8th, at the Parish Church, Henley-on-Thames, Captain J. M. P. Bliss, M.C., R.A.M.C., to Violet Mary, only daughter of the late John Manning-Cooper, Melrose-avenue, Orkneywood.
 MACKESSACK—RIBTON GORE.—On Jan. 9th, at the Church of St. James the Less, Plymouth, Captain R. C. Mackessack, R.A.M.C., to Ada Mary Frances, eldest daughter of Colonel and Mrs. Ribton Gore, Thornfields, Lisnagry, Co. Limerick.
 STOUT—PIKE.—On Jan. 8th, at Sutton, Surrey, Douglas Garnet Stout, Major, R.A.M.C., of Georgetown, Demerara, to Margerie Anne (Nancy) Pike, of Sutton.

DEATHS.

BERNARD.—On Jan. 7th, at New Silkworth, Sunderland, Gerald Bernard, M.D.
 BUTCHER.—On Jan. 10th, at Holyrood, Cleveland-road, Ealing, William Deane Butcher, M.R.C.S., aged 71.
 THORNTON.—On Jan. 8th, on the eve of his 85th birthday, Surgeon-General Sir James H. Thornton.

N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

HEALTH, MEDICINE, AND SANITATION IN INDIA.

1.
 THERE has recently been presented to Parliament a statement exhibiting the moral and material progress and condition of India during the year 1916-17. The following are amongst the references to health, medical, and sanitary matters contained in it:—

Medical Administration in War-time.

The year was marked by an unprecedented and almost unlimited growth in military medical administration. There is not space to record in detail the list of new hospitals, instituted or taken over by Government, the great expansion of many existing hospitals, the large number of fresh medical units established for service overseas or in India itself, the immense additions made to personnel and equipment, and the special preventive measures organised against infectious and epidemic diseases, flies, heat, glare, and other discomforts incidental to campaigning in the East. We can mention here only two matters of particular interest.

The first is a new departure in the foundation of orthopaedic institutes for the treatment of wounded and disabled soldiers. A large and very fully equipped institute of this kind is being established at Dehra Dun, and the King Edward Hospital at Cawnpore has also been taken over for conversion into a special orthopaedic hospital for Indian soldiers. Another such institute has been founded in Bombay.

The second matter is the increasingly difficult problem of providing trained medical officers. The civil side of the Indian Medical Service is not only the Government channel of medical administration and instruction for the whole of India, but it forms also the reserve of medical officers for the Indian Army on mobilisation. All Indian Medical Service officers liable to surrender from civil employ were returned to the Army in the very early stages of the war, and many others not technically liable were returned with or soon after them. Only the barest minimum of officers was retained to occupy the most important of the administrative and executive charges and to maintain at full working pressure the medical schools and colleges on which practically the whole supply of medical practitioners, official and non-official, in this country depends. Even so, the numerical strength of the service proved far below military demands, and has had to be supplemented by the grant of temporary commissions to numbers of civil assistant surgeons and private practitioners. Still greater difficulties beset the provision of subordinate medical officers for the Army. Exceptionally favourable terms have been offered to induce civil sub-assistant surgeons to enter military employ, but the number of candidates is still far short of requirements. On the other hand, there is a point beyond which the medical needs of the vast population of India cannot be sacrificed, and we have every reason to believe that the response already made to military demands has reduced the available medical personnel in most provinces to that point. Government has in this matter a responsibility to the civil population of India which it must discharge, and were a widespread increase of plague or other epidemic to find it unprepared and inadequately equipped the consequences would be disastrous.

Public Health and Medicine in Madras.

In the days before the war it was a common charge against the organisation of medical relief in India that the staff was quite insufficient to supply the needs of both the military and civil branches in the contingency of a great war. That there was some measure of reason for this apprehension can be seen from the fact that the Madras Presidency has had to surrender to the military department all its Indian Medical Service officers, except 16, in addition to 27 assistant surgeons and 76 sub-assistant surgeons. During the past year, in spite of shortage of staff, and notwithstanding financial difficulties, it was possible to increase both the number of institutions and the number of patients relieved, while at the same time there was a pronounced fall in the hospital death-rate. This state of affairs could not have been maintained had it not been for the efficiency of the remaining officers of the superior service, who have each been doing several men's duties, and of the assistant surgeons who have been called on to take charge of important hospitals.

During the year 1916-17 more than seven million patients were treated in the public hospitals and dispensaries maintained or aided by the State and by local bodies. There was a very large and satisfactory increase in the number of medical students, due partly to the opening of a new medical school at Ollent. The Pasteur Institute treated a record number of patients, and efforts are being made to collect reliable statistics as to the efficacy of the treatment.

In Madras City a careful malaria survey has been made and preventive measures have been taken on a fairly large scale against this disease. By means of itinerating dispensaries something is also being attempted in the Mufassal, but the huge area over which malaria prevails precludes any possibility of concentrations of effort such as have been successful in the cities of Europe and America. Great differences of opinion exist as to the efficacy of the measures taken in the Madras Presidency for the prevention of the spread of plague, but the fact remains that the larger part of the Presidency has enjoyed a comparative immunity from the disease, which may or may not be ascribed to the working of the plague passport and notification systems. As regards cholera there has for some time been a tendency for epidemics to be less serious and more local. It is hoped that the improvement of water-supply and the spread of education in hygiene will, in a very few years, reduce the mortality from cholera to much smaller dimensions.

Bombay.

The year was far from being as healthy as its predecessor, and the number of in-door and out-door patients treated in hospitals and dispensaries showed a further increase. Among in-door patients this occurred chiefly among cholera, small-pox, and malaria cases, while malaria was the chief disease amongst out-door patients. Eight sub-assistant surgeons were placed on special duty in the most malarious parts.

The second half of the year was marked by a rise in plague mortality, which reached its maximum in December. The Deccan districts, the Southern Mahratta country and Bombay City were most seriously affected, but deaths were reported from all except three districts. Special inoculators were sent to the badly-infected districts, and inoculations were performed on a larger scale than in 1915-16. As usual, these resulted in a much lower incidence of attacks of, and mortality from, the disease amongst inoculated persons, and confidence in inoculation is steadily increasing. Work and investigations in connexion with rat destruction were continued, and hydrocyanic acid gas was tried as a suitable poison for rats and fleas in houses and grain stores.

From cholera the heavy mortality of almost 20,000 deaths was recorded. Most Khandesh and other districts, to which the disease spread from it, were the chief sufferers. In sanitary matters arrangements have been made for the examination of drinking-water, the supplies of various important towns have been improved, and a committee investigated the problem of the sanitation of pilgrim centres, which are a fruitful source of epidemic diseases. Small-pox cases were more numerous than in the previous year, but less than the decennial average. Vaccination is voluntary except in the large towns, and is being popularised by the use of glycerinated calf vaccine. District sanitary associations have been formed and have done useful work, while a sanitary demonstration held at Belgaum was largely attended.

A new civil hospital was opened and another completed during the year. Six taluka dispensaries were also opened and many additions and improvements made at civil hospitals. To spread a knowledge of the danger of tuberculosis instruction to school teachers and children was given and lectures and demonstrations were held. Owing to the war the medical services have been depleted to the utmost extent, and the loss of staff and curtailment of expenditure make present progress difficult. No fewer than 43 officers in the medical service out of the sanctioned staff of 58, the entire staff of military assistant surgeons employed on civil duties, almost one-third of the civil assistant surgeons, a large number of civil sub-assistant surgeons, and many of the nurses and the trained servants of civil hospitals were surrendered to meet military requirements. In spite of this depletion a large military hospital in Bombay was worked by a civil medical staff, and various civil hospitals have undertaken the treatment of military cases.

(To be concluded.)

THE BISMUTH ORDER.

THE Minister of Munitions has modified the Bismuth Order made by him and dated March 12th, 1918. On and after the 10th day of January, 1919, Clause 2 is to be omitted and a fresh Clause 2 (b) substituted. This sets out that no return is required from any person whose total stock in hand is not intended to be used in connexion with the manufacture of metallic alloys and who has not, during the period for which a return was necessary, exceeded a supply of 56 lb. of bismuth metal or any alloy thereof.

*LEMON JUICE OR LIME JUICE?

To the Editor of THE LANCET.

SIR,—Mrs. Alice Henderson Smith, in her most interesting paper (THE LANCET, Nov. 30th, 1918), for which we must all be grateful, says that "about 17 years later" than the return of Sir John Ross, therefore about 1860, the Admiralty began to use true lime juice, which is not antiscorbutic.

Could she certainly say if it was lime or lemon juice used in the Crimean War and in the Baltic (1854)? I write far from books of reference, but I remember that in the Baltic a French ship suffered severely from scurvy, met an English frigate (*Meander*), and got from her "lime juice," which speedily cured the scurvy. This was, I now suppose, probably lemon juice; could Mrs. A. H. Smith perhaps tell us?

For the papers of Miss H. Chick and others on vitamins we must all be greatly obliged to them.

I am, Sir, yours faithfully,

W. E. HOME,
Fleet Surgeon.

Dec. 13th, 1918.

NEW RECORDS CONCERNING IMHOTEP (ASCLEPIOS).

SOME 13 years ago considerable interest in connexion with the history of ancient medicine was aroused in the career of Imhotep, the celebrated physician of a very early age in Egypt, whom the Greeks subsequently associated to Asclepius. This sage's story was elaborated with considerable skill from the fragmentary evidence of papyri and inscriptions by Professor Sethe and others, and ably utilised by Dr. Richard Caton for the Harveian Oration of 1904. Some years later an important Greek papyrus concerning Asclepius-Imhotep was published by the Egypt Exploration Fund, and summarised in our pages.¹ Since then, excepting a few references in Egyptological journals, the matter has not received any further elucidation.

In last year's "Bulletin de l'École Française d'Archéologie Orientale" of Cairo, M. Henri Gauthier has edited "Un Nouveau Monument du Dieu Imhotep." This is an inscribed base, or plinth, for a statue of a personage named Pedubastit (which also gives the name of his wife and three daughters). He was a prophet, or priestly scribe, of Imhotep, who is therefore in the record recognised as a deity and he is styled son of Ptah in the texts. Pedubastit's religious duties, among other matters, consisted in seeing that the various ancient fêtes or holy days of Imhotep were properly

observed, and in the panegyric of his career he sets forth these days fully in a list giving six dates, but not in the correct chronological order. In another text upon the same stone, however, Pedubastit, or his survivors for him, more completely describe the events in Imhotep's life which caused each day selected to have been reserved for a festive in his honour.

This information is new and of great interest. The first occasion for commemoration was Imhotep's birthday 16th of the month Epiphi. His mother is stated to have been a lady named Khardit Ankh. The second fête was the anniversary of Imhotep's presentation to his divine father Ptah and to Sekmet, a goddess, parda of Ptah. The third day was kept in honour of "the time when Sekmet destroyed the vile Asiatics in a naval battle upon the re lake." The fourth day, 17th of month Mesore, was, according to M. Gauthier's reading of the new-found records, that of Imhotep's death, and the 23rd of the same month that of his burial.

Other Egyptologists who have read the inscription dispute this rendering, thinking the fourth fête was that of the onset of the physician's fatal illness and the fifth that of his decease. Only a few remarks are possible here. Firstly, as contrary to M. Gauthier. During his career as a physician Imhotep must have become famed for his medical skill, and consequently revered. But it was probably not until long after his earthly career had ended that he was canonised and finally alleged to have been of semi-divine origin and so a deity. This was a common assertion as to procreation of the deified Pharaoh. It is obvious that the fête day of Sekmet's victory was foisted into the catalogue of the medical hero's memorials. However, Imhotep at some remote date was deified. Now an interval of but six days between death and burial was insufficient to perform the funerary rites and proper mummification of even the poorest personages, but it is just possible that Imhotep died in a year when the Egyptians inserted an additional month to rectify their calendar—if so it would give 35 days. On the other hand, verily a festival in honour of the illness of a god of healing would have been curiously contradictory. Moreover, there is great weight in an argument used by M. Gauthier—i.e., that never does an Egyptian text refer to the illness of a deity, neither does the writer ever recollect even a reference to individual illness except in medical papyri or in some book of a Job-like type in which the author laments senile decay. The thousands of obituary notices merely state a person was born in a certain year, died in a subsequent one, and sometimes enumerate the length of his life. However, the monument tells us that on the fourth day of the month Paoni Imhotep's spirit departed for Paradise. It adds that he was interred in the great Dehan which is believed to have been a vast cave, or excavation, in the desert near Memphis. In later time its surrounding land had become an immense Campo Santo. It probably bore some title indicative of being sacred to Imhotep, which word the Greeks rendered as "Asclepeion."

Also we have many inscriptions omitting all reference to his godship, while Imhotep's titles, too, are human enough, so also are his parents and wife. It is evident that, in time, there were two traditions of him. One, the oldest, makes him a marvellous physician, and great in other sciences and friend of royalty. The second speaks of him as a deity. The new papyrus of Imhotep Asclepius referred to throws no light upon the subject. It is a literary effusion of a Greek author who, after Imhotep had been identified with Asclepius in order to exalt him, alleged that Menkaura, the builder of the Great Pyramid, had granted certain bounties to Asclepius, son of Hephaestus, and to two other people named Horus and Caleobis, who, he says, were sons of Hermes and Apollo. Horus was not, however, son of Hermes-Thot, but Apollo himself, whilst Caleobis is unknown. Imhotep was not an uncommon name in Egypt and Horus was still more frequent. There may have been sepulchral texts near the pyramid of people with these names, or the statement may be pure invention. The other new-found record discussed here is of value as confirming the fact by an inscription of one of his temple hierophants that Imhotep was deified and had numerous worshippers.

THE USE OF CREOSOTE IN INFLUENZA.

To the Editor of THE LANCET.

SIR,—The use of creosote during the recent epidemic appears to have been fairly general, but what has impressed one more particularly has been the manner in which it has been possible to abort pneumonia. I had been sceptical of this until several cases occurred, and I am personally convinced that this has been due to the creosote and potassium iodide. I doubt if this has received sufficient attention, the early exhibition of this drug is of such capital importance: in some cases one has found that the patient has been unable to accept creosote in mixture, then resort has been made to capsules or some preparation of guaiacol in cachet.

I am, Sir, yours faithfully,

Jan. 11th, 1919.

I.M.S.

A Personal Retrospect of GENERAL PRACTICE.

By JAMES PEARSE, M.D. EDIN.

SOME LIMITATIONS OF GENERAL PRACTICE.

It is a frequent statement that the accumulated experience of the general practitioner finds inadequate expression, and adds too little to the store of scientific knowledge of disease. Too much may readily be demanded from this source. The nature of the general practitioner's work leaves him as a rule little opportunity for the reasoned and detailed consideration of the items of his experience, and he perforce has in general to be content with the immediate alleviation of disease and to leave considerably to others the direct advancement of science.

Allowance, however, being given to this consideration, a personal retrospect cannot but leave a sense of disappointment that, though there may have been some gain of one's individual knowledge, there has been complete failure to add even an iota to the store of general knowledge. "Produce," says Carlyle, "produce: were it but the infinitesimal fraction of a product, produce." Alas for the failure to respond to that call from Sartor, the Bible of early days of struggle! But why the failure, and wherein is it of general application? Partly temperamental; and it would be unreasonable to expect advanced scientific work from every general practitioner. It is not every mind that has the scientific bias; not every medical student is a budding Pasteur. The faculty of practical application of knowledge, which is the essential rôle of the practitioner, is often divorced from the faculty of coördination of experience and inductive reasoning therefrom. Partly educational; and looking back upon one's training one realises that there was too little evocation of individual powers of reasoning, presentation of items of acquired knowledge with insufficient stress on the unexplained factors the elucidation of which is necessary for a fuller understanding of the problems of disease. In short, the student is apt to blossom forth into the practitioner, feeling that his knowledge is gained and that his function henceforth is only to utilise it. The bias thus given to the mind has been retained, and the *mens media* has grown as a crystal grows, by accretion, and not as an organism by absorption, metabolism, and development. Herein is the essential need, the need of vital reaction. The danger is that we all tend to be creatures of habit, slaves of routine, to work as a machine in an accustomed groove, to do to-day what we have done yesterday, to wear blinkers whereby our vision is limited. It is difficult to resist this tendency, and only the favoured few can fully do so and retain a mind impressionable, alert, imaginative, vital. Hence the failure to see in any presentation of disease more than has been seen before or the textbooks have revealed; hence an unwillingness to test authority by experience; hence the submergence of the individual mind, and the bondage of tradition. This tendency is to a certain extent inevitable. It is a counsel of perfection to expect the busy practitioner after long days and disturbed nights to keep his mind ever alert; moreover, the individual patient asks to be relieved and not to be studied. Neither is the tendency altogether to be deplored; the human material dealt with is too precious, the interests at stake too vital, to allow with safety the unbalanced play of minds "complexionally propense to innovation." The middle course is to be desired. And such consummation is the more likely to be attained if the young graduate should leave the portals of his school, not only with a mind stored with ascertained facts, but should carry with him and retain some vision of the unexplored domain, an awakened sense of the responsibility and power of individual thought, heightened by a knowledge of the work of those who have broken ground before them untitled.

UNCHARTED SEAS.

Medicine, it has been said, is an inexact science. Its practice is sometimes an object of scornful criticism by those who have no inner knowledge of its difficulties and may be accustomed to deal with subjects more demonstrable and less elusive. Again, many of the public appear

to regard the practitioner of medicine as one whose brain is compactly pigeon-holed into compartments, each labelled with the name of a disease and carefully docketed with the appropriate remedy. Alas, the matter is not so simple that there is never room for hesitancy; but one soon finds that to express hesitation is to be lost, and to be in doubt is interpreted as weakness. And the young practitioner himself is apt to start out with a perhaps undue consciousness of the fullness of his knowledge and of the resources of his scientific equipment, soon, however, to find himself in uncharted seas.

Two considerations lend themselves to this misconception. In the first place, disease as seen in practice is often not according to schedule. Disease as portrayed in the textbooks is an entity, a finished picture, a completed building, an orderly procession; illness, as frequently seen in the consulting-room, is not a definite entity, is ill-defined, incomplete, refuses to be labelled, presents a disarray of vague symptoms. It is with this sphere of vague illness, of initial stages, of the symptomatic manifestation of ill-defined disease, of functional disorder, that the work of the general practitioner is largely concerned. Such illness does not lend itself readily to clinical teaching, or exact portraiture; its origin and course are frequently obscure and its treatment outside the range of ordinary routine. Thus it has not come readily within the scope of early systematic training, and the practitioner must gain his knowledge from his own experience and the exercise of his own judgment, strengthened, if possible, by contact with his seniors in assistance or partnership. The second consideration, which is associated with the first, and which goes far to explain the inexactitude of medicine, is that the practitioner early discovers that he is not so much called upon to treat disease as to treat persons who are ill; in other words, that he has to deal not with a mechanism, but with a delicate organism inhabited by an individual. It is not only the gross effects of disease which have to be countered, but the reaction of an individual to such disease. There is always the personal equation. It would almost seem as if there were a physiological or a pathological character. The author of *Hydriotaphia* finds individual divergence even in decay when he states, "bodies in the same ground do not uniformly dissolve, nor bones equally moulder." Even in the more definitely objective types of disease no two cases are exactly similar; no two cases of enteric are identical in course and manifestation, one case of pneumonia differs from another, carcinoma may develop aberrant processes. But the personal equation is much more than this. There is the individual characteristic; his general attitude to life, the courage with which he meets the strokes of fate, his kicking against the pricks, his equanimity or irritability, his self-concentration or self-forgetfulness. And other factors enter in: the wisdom or unwisdom of relatives, business anxieties, family anxieties, all the social factors which are involved when illness lays a heavy hand on a household, or extinction threatens a life on which affection is centred. Here, then, is an uncharted sea in that the family practitioner has to face more than the mere problem of disease. Said Bacon:

"Physicians are some of them so pleasing, and conformable to the humour of the patient, as they press not the true Cure of the Disease: and some other are so regular in proceeding according to Art, for the Disease, as they respect not sufficiently the Condition of the Patient. Take one of a Middle Temper."

There is an art as well as a science of medicine. The practitioner is incomplete who has the art without the science, or the science without the art; but incomplete also if the science and the art are limited to medicine alone, for the field is wider far. Hence the necessity for a width of outlook in medical education, for a knowledge of the humanities, for a social interest: herein the factor which precludes the supersession of the general practitioner by the specialist: herein the necessity of visualising the human factor in disease.

SOME DIFFICULTIES OF GENERAL PRACTICE.

For those men who do not succeed to established practices there is a varying period of waiting for patients, followed by a period of moderate success, and then, if fortune and merit favour, a period of unremitting activity. Sir Andrew Clark is said to have stated that he strove 10 years for bread, 10 years for bread and butter, 20 years for cake and ale. The early years are not pleasant to live through, but

they bring a pleasure in the retrospect of difficulties surmounted. They have their special dangers—financial anxiety, the ennui of idleness, the temptation to use specious methods of advancement; they have their advantage in a continued opportunity for study, and in the fact that work when it does come may be done without rush in thoroughness, and thus a good foundation laid.

But the difficulties of the general practitioner arise more especially in the busy years, when there may be not too few but too many patients to be seen, when the day may bring no interval for leisure and the night be often robbed of rest. There are men, who are to be envied, who can compass a large amount of work without evidence of haste and who, however busy they may be, leave a patient with the impression that he only is the chief concern. But others of us in busy times are conscious of a constant sense of strain, of thinking in one house of the next, of a feverish anxiety as to how the round of the day is to be completed. It is in this atmosphere of haste that some of the main difficulties of general practice are to be found. It has often been said that mistakes are made not from lack of knowledge but from lack of examination. Full examination is neglected not so much from carelessness as from absence of sufficient time for thorough review. Thus the work is left to the next visit or consultation, or to the one after that, and may be still postponed, until complications may develop or the patient go elsewhere, to the detriment of reputation.

There arises from this another danger, that of the mere symptomatic treatment of disease. It is a commonplace statement that such symptomatic treatment is sometimes all that can be compassed, as the ultimate cause may be obscure and undeveloped. Also the patient demands relief from urgent symptoms, and relief can often be given. But the tendency grows all too readily to be content with the alleviation of the obvious, to fail to probe to ultimate causes, to forget the guiding rule *causa sublata, tollitur effectus*. Hence the relief of pain by analgesics, of insomnia by hypnotics, of debility by tonics, of dyspepsia by drugs alone, while the essential cause remains untouched. An associated tendency is that of routine. It is so much easier to do what one is accustomed to do than to follow on and develop new ideas. And this is an inevitable result of an experience which sees so many new ideas and suggestions fail to stand the test of time and yield their place again to old-established method. In the youth of practice one tries with enthusiasm every new proposition: in later years one waits to see if the new is to be permanent. But though there is reason for such attitude it is difficult to escape an undue conservatism, a blind adherence to established routine, and to avoid "the great tendency of the human mind to fall into a groove and pursue its work on lines that give no occasion for mental strain."

A further danger is that which, for want of a better term, may be designated "staleness." Its occurrence calls to mind the teaching regarding summation of stimuli, that under the frequently recurring influence of electrical stimulation a muscle gradually reduces its response and finally fails to react further. It produces the failure of the most obvious diagnosis, and the feeling under which every difficulty is magnified, and "the grasshopper becomes a burden." It is not that knowledge is lacking, but that the tired mind fails to absorb the transmitted impression. Probably most practitioners in times of stress have realised this; well for them if, recognising the danger-signal, they can find relief in a well-earned rest.

A further danger associated with the fullness of the practitioner's life is that which may always follow excessive concentration on one subject—namely, a failure of interest in other spheres of life. It is illustrated by the fact that few general practitioners retire from practice: the majority die in harness. The reason, to a large extent, is that not many are able to lay aside the means to provide for later years; but a further reason is that work has been so absorbing that there has been too little opportunity for the cultivation of hobbies or outside interests, and thus without the interest of work life would be lacking in zest.

These seem to be the especial dangers of which a personal experience of general practice has brought cognisance. They are not all peculiar to the calling of the practitioner, but there are special features of his life which give them

prominence. Herbert Spencer, in a criticism that education deals inadequately with the conduct of life, says that the question "Is it worth while?" is not asked with sufficient frequency, and emphasises that work exists for life rather than, what is the more currently expressed view, that life exists for work. To this question the practitioner of medicine cannot reply only from his own point of view: others may, perhaps, be in a better position to answer for him. But it may be well sometimes to ask the question and consider whether too heavy a price is not being paid, especially if the price may possibly involve the risk of deterioration in value.

SOME REQUIREMENTS OF THE GENERAL PRACTITIONER.

Every practitioner who has carried on practice for any considerable time must recognise that he is faced with special difficulties unknown to his predecessors. For them the years brought but slow advance in knowledge, and they were perforce in the main dependent upon their own developing experience. All this is altered; changes have been so revolutionary that no man, even of the widest experience, can feel that this alone is a sufficient equipment. Who amongst us who graduated even 20 years ago can pretend to an accurate knowledge of late developments? It is sufficient to state a few of these—the intricacies of cardiac diagnosis; the theories of immunity and vaccine therapy; the action of the internal secretions; the extended use of X rays; the diagnosis and treatment of syphilis; the various blood changes. It is impossible for the general practitioner with little leisure to be thoroughly conversant with all new work. Yet that he should have a working knowledge of it is essential. Many men, to their credit, strain every nerve to extend their knowledge and adaptability and to maintain themselves abreast of the times. Others give up the effort and two tragedies may occur: the tragedy of lives hazarded by imperfect diagnosis or treatment, the tragedy of practices lost to younger men with fresher knowledge.

It will thus be seen how essential it is that medical practice should be combined with continued study. The desirability of this will be generally admitted but its attainment is not easy. When once a man has developed a busy practice the demands on his time are so continuous, periods of leisure are so scanty, that opportunity for study is but limited. However laudable intentions may be, attainment of necessity lags behind.

There are three directions in which it would appear that this requirement might to a certain extent be met.

1. Post-graduate Study.

Facilities for such exist, but only a limited number of practitioners are able to avail themselves of these. Holidays from general practice are rare and refreshing, and no small degree of enthusiasm is needed to forgo such for the sake of study. And to leave a practice for any lengthened period is both costly and hazardous.

Some modifications of the present system seem worthy of consideration. The number of centres where post-graduate training has been developed is limited. The development of such work at other centres would be an advantage, especially if the work were so arranged as to be available to practitioners in the adjacent area without undue absence from practice. Many practitioners who would find it impossible to attend a prolonged session would make an effort to attend a short course—for example, a series of lectures on six or eight afternoons or evenings once a week; and in a specially adapted course much might be learnt in that limited time.

A further modification might be advisable as applicable for more rural areas where even the limited attendance above indicated would involve too long absence from home. There might be developed extension lectures in medicine, and a lecturer attend occasionally at a given centre in the country for the enlightenment and encouragement of the rural practitioner. True, such lectures could not be attended by a large number, and would not be directly remunerative to the lecturer, but their value might be very great.

Further, the hospitals might render very material assistance to the general practitioner by developing courses of clinical lectures at times adapted to his convenience. And especially would this be the case if use were made of hospitals not only in the recognised teaching centres, but also of those situated elsewhere.

Developments such as these would have far more than their direct teaching value. Medical men, who too seldom

¹ Mackenzie: "Interpretation of Symptoms."

meet in fellowship, would be brought together in the pursuit of knowledge. They would form contact with a larger sphere than that in which their daily work is often cast; their horizon would be extended and they would return to their work with a heightened interest and zest. With all its variety, even medical work is apt to become monotonous; there are times when the interest of the most zealous will pall, and his mind become stale: whatever will counteract such tendency is of value not only to the practitioner, but also to the community.

2. Specialist Facilities.

No practitioner can now have at his immediate disposal the whole equipment necessary for the adequate diagnosis and treatment of disease in accordance with modern requirements. Neither can any practitioner have the requisite knowledge to use such equipment in every variety. Where resources other than his own are required he must send the patient elsewhere, and often to a considerable distance. The advantage or disadvantage to the patient is not now under consideration, but the result to the practitioner is that with much more frequency than was formerly the case he must lose touch with his patient, even in the matter of diagnosis. The danger is lest he become a mere sieve for the sifting out of cases, and that those requiring refinement of diagnosis or technique pass beyond his ken. With such an issue his mental power must inevitably decline and his usefulness to the community diminish. Thus an extension of specialist facilities, so that there might be more ready access for the average general practitioner, would be a great boon. Especially is this true as regards the practitioner in the country or the small country town. The city practitioner has facilities at hand, and may have access to them when he will and if he will. His more isolated colleague is by his isolation handicapped; he may send a patient to be X rayed and have to be content with a photograph, which perhaps he does not understand; he may receive a detailed diagnosis of an obscure heart case, but know nothing of the technique involved; he may send a scraping of a chancre to a pathologist, but the spirochæte may be only a name. *Experto crede.*

The continuous development of the general practitioner, which is so essential, is impossible without an extension of facilities. But here, again, the middle course is the safest. To spoonfeed the practitioner, to encourage him to depend too exclusively on the resources of others, would be disaster. Isolation or semi-isolation is not without its advantages; it develops a resourcefulness and self-reliance which in many an instance are of more avail than the most up-to-date knowledge. Many a country doctor will perform, as part of his recognised routine, surgical operations which a London West End practitioner, in receipt probably of a much larger income, would consider as beyond his province.

3. Medical Literature.

Post-graduate studies have their place, specialist facilities have their place, but the main resource of all practitioners must be in medical literature. Research herein is again beset with difficulty. In the early years of practice there may be abundant, even too abundant, time for reading, but this suffers from not being brought to the bar of sufficient experience; in later years stress of work and scanty leisure allow little opportunity for study. Hence a tendency to depend upon the knowledge gained from accumulated individual experience without refreshment from other minds. Moreover, as years increase, there tends to be a less open mind, less adaptability to new impressions. Bacon has said:

"For it is true that late learners cannot so well take the plea: Except it be in some Minda that have not suffered themselves to fixe, but have kept themselves open and prepared to receive continual Amendment, which is exceeding Rare."

This lessened pliability of mind reinforces the difficulty induced by diminished opportunity for study, and the tendency grows to be content with an occasional dip into a medical journal, and to leave aside deliberate and purposeful study.

It is not, however, from this point of view that the subject is mainly considered. These are the difficulties of the practitioner in approaching medical literature, but they are too often enhanced by the methods of presentation of such literature. The assistance which the practitioner seeks from books is mainly in two directions—clinical instruction which will help him in his daily round, and instruction in new developments. As regards the former there has

been much improvement in recent years. Time was when there were only ponderous tomes, weighted with unrequired details, which had to be laboriously sifted in order to obtain the essential knowledge. The practitioner does not require the elaborate text-book, but the graphic presentation of the essentials of diagnosis, prognosis, and treatment—the clinical portrait. It is on the clinical lecture of his student days, impressed by the personality of his teacher, that his knowledge of practical medicine is really based, and it is the continuance of such vivid type of teaching that he still desires. That such literature is more in evidence is of good omen, but there is still a tendency to dwell unduly on the rare.

More difficulty is experienced in following writers in the later fields of research. Perhaps it is because much of the new work is done in the laboratory, but certain it is that the language in which it is expressed is often far from easy of comprehension. It must be difficult for those working in these fields, to whom new ideas and new terminology are current knowledge, to realise that many practitioners have yet the alphabet to learn of their science, and that what is to themselves a simple statement may be to others a maze of intricacy. But it would be well if writers were more adequately to visualise their audience, and study their expression and terminology, not from the point of view of those who write, but of those whom the writers address. No grown man expects to be fed on pap food, and it is always well to have some mental pabulum on which to bite hard; otherwise the thinking faculties may atrophy. But the more difficult a subject the more necessary that its exposition should be divorced from needless obscurity.

VIS MEDICATRIX NATURÆ.

One lesson, of principle rather than of detail, emerges from experience of general practice—namely, a recognition of what is involved in the *vis medicatrix naturæ*. As young practitioners we are apt to commence with a consciousness of knowledge, with a sense of our primary importance as agents; experience brings the recognition of a secondary place in waiting on and assisting the efforts of Nature. "Knowledge is proud because he knows so much, Wisdom is humble that he knows no more."

The objective manifestations of disease are often to be regarded, not necessarily as morbid processes, but as the efforts of Nature to be rid of a foreign element, to limit its activities, or to minimise its ill-effects. Pain is a warning; the rigidity of muscles is a protective effort; the effusion of serum is a separation of inflamed surfaces; the formation of pus is directed to the removal of a noxious agent; the swelling of glands is evidence of a defensive organisation; elevation of temperature is not necessarily an evil. Nature is always on the alert and resents disease in man. The recognition of that fact leads one to watch her efforts and to take a second place. It awakens the consciousness of an agency other than one's own, brings a realisation of power and law in coöperation with which lies one's sphere. It brings reliance on the common-place, on rest, on dieting, on fresh air, on sleep, on exercise, on the simple life. It emphasises the removal of hindrances to health as preferable to active interference when health has become unbalanced. Recognised by the medical attendant, the carrying out of this principle is often obstructed by patients or the friends of patients who exemplify the spirit of Naaman, who, wroth at the simple instruction to go and wash in the Jordan, demanded drama and that the Prophet should surely come to him and call on the name of the Lord and strike his hand over the place. Herein is an advantage that surgery has over medicine, that its action is so much more frequently immediate, direct, and impressive. And it is recognised, of course, that there are conditions, especially surgical emergencies, which constitute a violent disruption of Nature and call for prompt and primary interference.

All this does not mean that the policy of the practitioner is to be one of drift or wholly of masterly inactivity. That the healing of a fractured limb is Nature's work does not preclude the necessity of careful setting; that pneumonia runs a recognised course does not preclude the duty of relieving a struggling heart, or aerating the lungs, or watching for complications; that labour is a natural process does not preclude a timely assistance or direct intervention when Nature is obstructed. In no way are the

duties of the practitioner lessened; but his attitude and activities are modified when his position as Nature's servant is recognised. Indeed, rightly considered, this tenet conduces not to a policy of *laissez-faire* but of increased resourcefulness. The recognition that disease is not inherent stimulates to search the cause of any deviation from the normal: should a case of illness not run the recognised course it postulates the presence of an unexplained factor and probes for such; it produces dissatisfaction with issue other than recovery.

And this creed brings with it another tenet—that of a reasoned optimism. Realising that Nature has many assets which postpone bankruptcy, one learns in certain cases to hope almost against hope. So many patients have been seen who recover from desperate straits that experience justifies a caution in expressing pessimism. This optimism must not be unreasoned: there are indications which cannot be gainsaid, there are conditions in which experience tells that the final ending is inevitable, but short of such the attitude of hopefulness and patience is often justified. In both the aspects considered—of waiting on the powers of Nature and of hopefulness—it is refreshing to bear in mind some words of Ambroise Paré. If any man, judged by our knowledge, had grounds for pessimism, surely he. But through his own records there run like a refrain the words, testifying the humility of greatness, "I dressed his wounds and God healed him"; and in reference to one case he states: "I told him that there was still some hope because he was young, and God and Nature sometimes do things which seem to physicians and surgeons impossible."

And there is a wider optimism which argues that if disease is resented in the individual so is it resented in the community, that its general incidence is not inevitable, and that the reaction of the larger organism is directed to its removal. The past 50 years have witnessed a revolution in the attitude to disease, wrought more especially by the work of Pasteur and Lister. They countered the doctrine, and the hopelessness engendered of the doctrine, of an inherent tendency to disease, of a *contagium sui generis*, manifested by such views as that there was a "morbidity spontaneity of the organism," that typhoid fever "is engendered by ourselves within ourselves," that there was "a spontaneous tuberculous degeneration of the organism," that the pyæmic infection was "tenacious and ineradicable," and that its source was to be found in "hospitalism." Pasteur wrote to Bastian:

"Do you know why I desire so much to fight and conquer you? It is because you are one of the principal adepts of a medical doctrine which I believe to be fatal to progress in the art of healing—the doctrine of the spontaneity of all disease."

This fatal doctrine has now gone, and a hopefulness has succeeded hopelessness. The counter doctrine is extending to fields wider than those of the infections, and the nature of causative factors is more generally recognised. But disease has been ever present, and familiarity therewith has bred the view of its inevitable occurrence. Inevitable it will be for a yet indefinite time. But the general practitioner who moves amongst various sections of the community, practising amongst the wealthy and the poor, amongst those well-fed and those under-nourished, amongst the well-housed and the ill-housed, amongst the over-worked and those capable of leisure, be they rich or poor, knows that the incidence of sickness and of types of disease varies according to the surroundings and circumstances of his *clientèle*. And experience justifies a reasoned optimism that with wider knowledge, a saner life, and a healthier environment the community will ultimately escape from many ills which now seem inevitable.

ON PROFESSIONAL RELATIONS.

The peace and happiness of a medical man's life is largely influenced by his attitude to his fellow practitioners or their attitude to him. The writer's lot was cast, so far as professional relationships were concerned, amidst pleasant circumstances. He remembers no single incident of rancour or misunderstanding, and for this he thanks the example of older practitioners. There is no doubt that such an experience is not universal, and that professional relationship often leaves much to be desired. Osler, in one of his addresses, says "No sin will so easily beset you as uncharitableness towards your brother practitioner." Why should this be so?

The work of a general practitioner differs from most other callings in the personal relationship it establishes with patients; it is not a mere exchange of goods, a business

transaction, not a mere giving of advice or a transient calling at a house, but a contact between individuals, an intimate reaction. Hence the severance of relation between doctor and patient cuts deeper than a similar severance in other spheres, and it is only reasonable to anticipate that it should create some heartburning. But it is unwise that it should be allowed to create bitterness. Just because the work so nearly touches human nature, and because human nature is so varied, is there the more scope for divergence. And it is unwise that secession should create animosity to the succeeding practitioner, but this is frequently the result. He is not of necessity a supplanter, and has not necessarily taken his place by devious and unprofessional ways. It is easy to blame the patient for whims and ingratitude, to blame the colleague for insidious advertisement, but a wiser rule is to consider in such case whether there has not been some error in one's own conduct or knowledge, and if this cannot be established to endeavour to cultivate a philosophic calm. After all, a patient has as much right to change his doctor as to change his grocer, and it would be well if this were more generally recognised. There are some words of Sir Benjamin Brodie in this respect which are worth remembering:—

"Taking all things into consideration it appears to me to be a question whether there is not, on the whole, more cause for wonder in the patience of the many than in the impatience of the few, and whether the gratitude of those who over-estimate our services does not even more than compensate for the neglect of those who withhold from us the credit which we really deserve."

Much depends upon the primary attitude to medical practice and its financial issue. Much sentiment has been uttered and written on the nobility and self-sacrifice of a doctor's work, sentiment which, to the credit of the profession, has often been justified. But a doctor has his obligations to meet as other men; he cannot educate his children on a reputation for philanthropy, nor live in old age on the memory of good deeds; he would not be human if he did not derive gratification from financial success. In any case, for the general practitioner such success is seldom proportionate to the strain involved, and it frequently arrives late, after years of penury and struggle. But there is all the difference in the world between a legitimate satisfaction in well-earned reward and a primary regard for the shekels. As an ultimate issue it is the difference between the love of work and the love of money; between the attitude which regards a patient as a person who is ill and the attitude which regards him as an individual who pays fees; between medicine viewed as a profession and medicine viewed as a commercial career. And if the fee aspect is unduly predominant there is an added likelihood of bitterness in the event of a patient severing relations. Competition is defined as "common strife for the same object"; if the object is the fee return it is obvious that what one gains another loses; if the object is the cure of the patient it really does not matter if the patient is cured by someone else so long as he is cured. Such detachment is not easy to attain, is probably only attainable by the few, but the pursuit of its attainment is a wise ideal. And after all, if patients never left us much needed stimulus would be lacking; a shock to equanimity and self-satisfaction is not without its value.

There is no work so individualistic as that of the general practitioner. Day by day he has to exercise his own judgment in vital matters; he is an autocrat whose word is law; he moves as it were in his own preserve, seldom challenged, responsible in his private practice to his patient and to himself alone. This individual and personal responsibility is one of the attractions of the practice of medicine. But it brings with it a tendency to come too little in contact with fellow-practitioners or to know them only as others engaged in their own special preserve. Anything which breaks down this tendency and brings medical men together, not as competitors but as participators in other spheres of life, is a great advantage; it brings the knowledge that the other man is not so bad a fellow after all, that he has human as well as professional interests and other objects in life than the purloining of patients.

SOME COMPENSATIONS.

I call to mind a Scottish country practitioner, who used to try to dissuade from the life of a general practitioner with the warning, "You are jist a body's body." "A body's body," indeed, he was over a wide stretch of countryside. Years afterwards, meeting in a railway carriage far

from the neighbourhood a fellow traveller from the same district, to the question, "Do you know Dr. —?" there came the reply, "Ken Dr. —? Why, he broocht me intil the world, and he's the finest pur mon's doctor that ever breathed." I see him now, aged, retired, with shattered health, and indifferent means, an ending to his days far other than he has merited, but withal content, and, I think, not regretful that he has been "a body's body." Another comes to memory who worked from youth to advanced years with almost unremitting toil, a man against whom no breath of evil whisper ever stirred, of whom I have heard it said, "If I had committed a murder I would go and tell Dr. —." Such an attitude is the result of the human relationship, the penetration to the depths of human life, the intercourse with its sanctities and woes, which is inherent in the work of the practitioner and which is the compensation for the difficulties of his life. The life-work of most other callings is less intimate, controlled more by the "tyranny of mere things." I recollect an incident related by a colleague of his entry to a sick room, and of how the patient, putting down a book which he had in his hand, and which happened to be the Bible, made the comment, "It's only the doctor." The observation on the incident was that clergymen see men at their best, lawyers see men at their worst, while doctors see men as they are. It is this touch of nature, this human intimacy, which leads many patients to regard their doctor, not as professional adviser only, but as guide, philosopher, and friend, and to seek his advice on matters outside his immediate sphere.

The general practitioner has, indeed, abundant opportunity for the observation of human nature. He presides at birth and is sought in death, he knows of the skeleton which is hidden in most cupboards, he knows the tragedies which blast a life, and the minor discords which embitter it, he sees human virtue and human frailty, joy and sorrow, life in its seaminess and life in its excellence. Well for him if he can preserve a genial toleration for the frailties of mankind and the spirit of charity. The contrary might be expected: as it is put by the Shepherd in *Noctes Ambrosianæ*:

"Physicians, ane might think, seein' folk deeing nicht and day in a' manner o' agonies, and bein' accustomed to pocket fees by the death-bed-side, would become in the core o' their hearts, as callous as cussocks."

As a matter of fact, though doctors spend most of their time battling with the ills of life, there are surely few in whom this engenders any spirit of resentment against Fate: and this from no lack of sympathy. In the first place they view these ills not from the point of view of philosophic abstraction but as men who are engaged in the concrete work of overcoming them, and who derive satisfaction therefrom. A further reason is that if they see much of the ills of life they see also much of the good, if they see many shadows they see also much radiance. They witness the pangs of labour, but also the joy that a man-child is born into the world; they company death, but know that he seldom comes as the King of Terrors, but often as "the poor man's kindest friend"; they see a child stricken low, but also the heroism of the nursing mother; they see uncharity and selfishness and vice, but also charity and self-forgetfulness and virtue. Doctors could reveal better than most men the degradation and sorrow of which human nature is capable, but also its elevation and joy. It is well to be impressed by the latter while not forgetting the former. If practitioners might enrich medical literature by a more frequent detailing of their clinical experiences they might also rebuke pessimism by a record of their human experience. One incident among many comes to mind. I recollect a visit to the cottage of a rural labourer. I see now, strapped to a chair in the garden, a repulsive form with enormous head and stunted limbs, speechless, helpless as a new-born babe, a youth of 14 years, idiot from birth: I hear now the mother's anxious query, "Have you come to take him away?" and her quick addition, with hand uplifted in emphasis, "Sir, I would not part with that child, though you gave me all between earth and sky."

But apart from this general human touch it is questionable if there is any sphere of work which can bring the same sense of direct pleasure in its fruition. The French have a saying, "Une cure c'est une paternité." And to tend a patient through a severe illness, to see him smitten down in the midst of robust health, to watch the descent into the valley of the shadow of death, to realise all that is involved

to those in anxious waiting, to watch again the gradual emergence to life and strength, and the final restoration; all this brings a sense of satisfaction which surely can be seldom rivalled by success in other callings.

It is not meant to imply that considerations such as these are the dominant factors in the practitioner's life. Perchance they only emerge when there is time and opportunity for reflection. It is a frailty of human nature to realise while engaged in a given occupation all the difficulties thereof, and to realise the advantages only when these are no longer at hand. And the difficulties of the general practitioner's life are obvious enough: stress of work, little opportunity for rest and recreation, frequent financial hardship, contact with folly and ingratitude, all indeed that is involved in being "a body's body."

This intimacy of relationship has its concomitant danger in that it may tend to the submergence of the strictly professional aspect, and there is an element of truth in the warning, "Never have your friends among your patients." But, and more especially in country districts, this is a counsel of perfection. It may be difficult, but is not impossible, to be the doctor as well as the friend, and the harmonious merging of the two is one of the chief compensations of general practice. It was said of Lister:—

"In early life Lister belonged to a Society the members of which called all men Friends, and now in turn because of his inestimable beneficence and service to mankind, all men the world over call him Friend."

Such an epitaph may not without fitness be applied to many members of the profession in less exalted spheres, who, if they have passed hence unsung, have not passed unhonoured or unwept.

January, 1919.

ACCIDENTAL HÆMORRHAGE IN CONNEXION WITH ECLAMPSISM.

BY SIR WILLIAM SMYLY, M.D. T.O.D., F.R.C.P. IREL.,
GYNÆCOLOGIST, ADELAIDE HOSPITAL, DUBLIN.

IN my opinion Schmorl was right when he stated that puerperal eclampsia is a definite disease peculiar to pregnant women and their infants, and characterised by peculiar pathological changes, consisting chiefly in thrombosis of blood-vessels, necrosis of the cellular elements of tissues, and hæmorrhages. Such conditions are, of course, met with in other diseases, but never so widely distributed, or involving so many important organs, as in eclampsia. They were found by Schmorl in all the necropsies on women who had died from eclampsia, and were considered by him to be essential to, and characteristic of, the disease; therefore, when they were present the case was one of eclampsia, when they were absent it was not. Subsequently he found the same pathological conditions in cases which had died in coma, but without any convulsions; therefore they also were cases of eclampsia, though they had no convulsions.

There can, I think, be no doubt that the so-called pre-eclamptic toxæmia is also essentially the same disease whether it culminates in fits or not; and since all these conditions are, therefore, examples of one and the same disease it is desirable that they should be grouped under one name. Eclampsia and toxæmia are not definite enough for the purpose, because the former is commonly applied to convulsions of all kinds and is hardly applicable to those cases in which there are none. Toxæmia, also, is unsatisfactory, because there are toxæmias which are not, as far as we know, in any way connected with eclampsia. Dr. Bar has suggested, and I think it an excellent suggestion, that whilst retaining the term eclampsia for the cases in which there are convulsions, we might employ the word "eclampsism" for those in which there are none.

Accidental Hæmorrhage.

One of the essential features of the disease, as I have already stated, is hæmorrhage; most frequently small petechial hæmorrhages, but occasionally very extensive, serious, and even fatal in amount. Anyone who has much experience of eclampsia must have met with such cases where the bleeding occurred into the brain, the eye, under the skin, or into the peritoneal cavity. But it is only recently that our attention has been called to the fact that

they occur into the uterus also; and the association of accidental hæmorrhage with eclampsia, or rather with eclampsia, has attracted notice. It would be impossible, in the present state of our knowledge, to say in what proportion of cases it occurs, but from personal experience I am inclined to believe that most of the cases of severe, and especially of concealed internal hæmorrhage are due to this disease.

Since Rigby taught us to distinguish accidental from unavoidable hæmorrhage our knowledge of its nature and treatment has developed slowly. We discovered in course of time that such hæmorrhages are frequently associated with albuminuria, and that those in which the effused blood is wholly, or almost altogether, retained are much more serious than those in which it escapes freely from the vagina. In attempting to explain these facts, however, it was assumed that the albuminuria resulted from a nephritis which, by causing endometritis, produced a diseased and loosely attached placenta. All that I believe to be erroneous, the condition of the kidneys is more necrotic than inflammatory and in the cases examined by Whitridge Williams there was no endometritis.

The treatment of concealed hæmorrhage by abdominal section originated with Dr. William Bagot, now of Denver, Colorado, when my assistant in the Rotunda Hospital, and was successfully carried out by him upon a patient in the extern maternity. But it was several years after that any other operator ventured to follow his example, and when in 1910 Dr. Amand Routh published a report upon 1280 cases of Cæsarean section, collected from obstetricians living in Great Britain and Ireland, it contained only three which had been done on account of accidental hæmorrhage. Since then, however, abdominal section has been resorted to more frequently, and is now, I believe, regarded as generally advisable in those cases, at least, in which the patient is not in labour, and the hæmorrhage is more or less concealed.

Pathological Conditions.

Since the introduction of this treatment which, in my opinion, marks a distinct epoch in obstetric history, we have learned that the actual conditions are very different from what we had imagined them to be. We knew, of course, that the placenta was detached from the placental site, and that the uterus was distended with blood; and we assumed, from the fact that the effused blood was not expelled, that there must have been a weakening or paralysis of its walls, but we had no idea, or a wrong one, as to its cause. Now we know that the blood is poured not into the uterine cavity alone but also into its muscular wall, which is suffused with blood, separating and no doubt injuring its muscle cells; sufficiently explaining not only the yielding of the uterus to the pressure of the blood, but also the extreme difficulty which has sometimes been experienced in controlling post-partum hæmorrhage. In many of the reported cases there was hæmorrhage also into the pelvic cellular tissue, especially between the folds of the broad ligaments, and in some into the peritoneal cavity.

In two cases reported by Whitridge Williams, in which the uterus had to be removed, the microscopic examination showed that the hæmorrhages had spread apart the individual muscular fibres and bands, and in places was associated with considerable œdema; apparently it was not connected with the larger vessels. Section through the placental site showed similar changes in the muscular wall, but the decidua were normal except for small hæmorrhagic areas. In this region many of the larger veins were almost completely filled with large thrombi, and many of the smaller veins were almost occluded with thrombi. The large arteries were normal, but many of the small ones presented changes in the intima, suggesting a mucoid change, and it projected into the lumen and in many places defects were observable in it.

The principal pathological conditions present, therefore, were thrombosis of veins, necroses of the intima of the small arteries, and hæmorrhages into and œdema of the uterine walls. This remarkable condition of the uterus has during the last few years been frequently noted by other observers in connexion with accidental hæmorrhage, and at a meeting of the Obstetrical Section of the Royal Society of Medicine in November, 1916, no fewer than eight cases were reported. In all of them in which the urine was examined it contained albumin; five had large hæmatomata in the broad ligaments and two free blood in the peritoneal cavity. In all of them

not only was the placenta more or less detached and the uterine cavity filled with blood, but blood was also extravasated into the uterine wall, most markedly in the superficial layers, and especially under the peritoneal coat.

Causation.

Couvelaire described this condition as utero-placental apoplexy, and although he believed it to be a constant feature in accidental hæmorrhage, yet he regarded it as a result of over-distension of the uterus, and not as the cause. If he were correct in this assumption, and the hæmorrhages were merely the result of over-distension, then their connexion with eclampsia is not so obvious as I suppose it to be. But if, on the other hand, it can be proved that this condition is not caused by over-distension, that it only occurs in patients with other symptoms of toxæmia, and that the anatomical conditions associated with it closely resemble those which cause hæmorrhages in other parts of the body in eclampsia, then it would seem to me a justifiable conclusion that it is due to the same cause.

As regards the theory that the remarkable condition of the uterus is merely due to its over-distension I would refer to experiments carried out by Dr. Arthur N. Morse in Yale University Medical School.¹ His first endeavour was to discover whether sudden over-distension could produce such phenomena. With that object he exposed, by abdominal section, the uterus of a pregnant bitch, inserted a cannula into it, and injected saline solution until it was distended almost to bursting. No ill-effects excepting abortion followed, and when the abdomen was again opened, after 48 hours, the previously distended horn was found to be entirely normal, without any sign of injury. That experiment proved that even extreme and acute increase in intra-uterine pressure did not cause an extravasation of blood into the myometrium.

A further series of experiments was carried out with a view to ascertain what would be the results of venous obstruction in a pregnant uterus. He discovered that in pregnant rabbits, when all the veins returning blood from a pregnant horn had been ligated, it became deeply cyanosed and distended, at first fluctuant but ultimately firm, tense, and resistant to pressure. After about two to four hours it was enlarged to about twice its former size and was quiescent, muscular action having ceased. The uterine cavity was filled with blood, which surrounded the unruptured foetal sacs; the placenta were partially or completely separated from their attachment, and minute extravasations of blood were visible in the myometrium. The microscope showed hæmorrhagic extravasations in the decidua, and at various points in the uterine wall, as well as dissociation of the muscle fibres; in fact, in every particular an exact reproduction of the conditions found in cases of accidental hæmorrhage.

Illustrative Cases.

The following cases, which came under my notice during the past four years, support the contention that there is a close connexion between eclampsia and accidental hæmorrhage.

CASE 1.—Patient, admitted to the Rotunda Hospital in March, 1915, under Dr. E. H. Tweedy's care, was pregnant about seven months. Her face, legs, and thighs were œdematous. She complained of intense headache, dimness of vision, and vomiting; secreted very little urine, which contained numerous tube casts and became almost solid when boiled. The blood pressure was 200 mm. Hg; in fact, a typical example of the pre-eclamptic state. The usual treatment was adopted, under which she appeared to improve. But at the end of a week she suddenly complained of violent abdominal pain, and a bloody discharge, which was slight at first but gradually increased to a considerable hæmorrhage, escaped from the vulva. The vagina was plugged, but though it controlled the external hæmorrhage her general condition grew steadily worse. The abdomen appeared to become more distended and tender to pressure, and from her general symptoms it was evident that serious internal hæmorrhage was continuing.

On opening the abdomen a considerable quantity of free blood was found in its cavity, the source of which was discovered in the right broad ligament, and a ligature thrown around the ovarian vessels on that side prevented further loss. The uterus contained a large quantity of blood and a dead fetus, which were removed by the ordinary classical Cæsarean operation, the uterus being left. There was no post-partum hæmorrhage, and she left the hospital in good health.

CASE 2.—Patient, aged 30, was admitted to the Rotunda Hospital on Sept. 1st, 1917, at 8.40 a.m. Her two previous pregnancies had terminated normally at full term, and on this occasion she had noticed nothing unusual until the previous evening, when she was seized with abdominal pain, and a feeling of distension, and she noticed an increase in the size of her abdomen. When admitted to the hospital she was in a collapsed condition, blanched, and cold; temperature 96.4° F.; pulse

¹ Surgery, Gynecology and Obstetrics, February, 1918.

hardly to be felt. The uterus very hard and tender on palpation; no foetal parts could be made out, no visible hæmorrhage, urine scanty, loaded with albumin, casts in large number, some pus and red blood cells.

It was decided to operate as soon as possible. When the abdomen was opened the uterus presented a remarkable appearance, dark, almost blue, in colour, with blood extravasation in patches over its surface, the peritoneal covering being in places raised in large blebs filled with blood, one of which upon the posterior surface had burst, the rent being about an inch in length; and there was free blood in the peritoneal cavity. When cut through the uterine wall showed blood extravasation throughout. The cavity was filled with blood and the placenta completely detached; the child, of course, was dead. After the uterus had been emptied and the wound closed in the usual manner it contracted well after a dose of pituitrin had been administered hypodermically. There was no post-partum hæmorrhage and she made a good recovery, the urine being free from albumin before she left the hospital.

CASE 3.—Patient, aged 39, 9 para, 36 weeks pregnant, was sent to the Rotunda Hospital by Dr. T. W. Rice, of Portlinton, and admitted on Dec. 7th, 1917. Twelve years previously her first pregnancy terminated prematurely at the eighth month owing to eclampsia, preceded by headaches and disordered vision, and since then the sight in her left eye had been impaired. She had convulsions and was unconscious for a week; the child was stillborn. The four succeeding pregnancies were normal and the children lived. But after the birth of the last child she did not make a satisfactory recovery, and had subsequently three abortions.

On admission the patient said that she had been ill for about three weeks, suffering from headaches and impaired vision. There was a large ecchymosis on the left buttock. Her urine was scanty and of a bright-red colour, and contained a large quantity of blood and tubercles. The child could be easily palpated, its head presenting in the first position. The diagnosis was pre-eclamptic toxæmia, and she was treated in the manner formulated by Dr. Tweedy, and which has been adopted as a routine in the Rotunda Hospital for some years; nothing was given by the mouth but water and bicarbonate of soda. She got little sleep in spite of a hypodermic of morphia, and the total quantity of urine passed in the first 24 hours was 20 oz. and the blood pressure was 260 mm.

The following day there was no improvement, and some twitching in the muscles of her arms, for which she was given $\frac{1}{4}$ gr. morphia. During the following days there was little change in her condition until the sixth day, when she seemed to be rather better and had passed 31 oz. of urine during the previous 24 hours, but in quality it was the same, and the blood pressure was still 260 mm. Considering that she had been restricted to soda and water for five days since her admission to hospital and that she said that she had eaten nothing for two days before, I thought it advisable to give her some nourishment, so at 12.30 p.m. she took 4 oz. of milk with an equal quantity of barley-water. At 1.10 p.m. she complained of a violent pain in her abdomen and said that she could see nothing. She looked pale and collapsed. Her skin felt cold and clammy and was bathed in perspiration. The temperature was below normal and a little reddish discharge flowed from the vulva. Her abdomen was evidently larger, the uterus swollen, hard, and tender, and the fœtus no longer palpable. Her condition appeared to be almost hopeless, but being persuaded that her life could be saved in no other way, I determined to operate immediately.

The abdomen having been opened, the uterus presented the same remarkable appearance which I have already described, being much distended, of a dark bluish-purple colour, with numerous patches of ecchymosis on its surface. The wall when cut through showed blood extravasated throughout its substance. The placenta was completely detached, the cavity full of blood and clots, and the fœtus was dead. To save time, which appeared to be of vital importance, I closed the uterine wound with a running suture of chromicised gut; otherwise the operation was carried out in the usual manner. Towards its close the patient appeared to be dead, but with the aid of pituitrin and other restoratives she gradually came round and was removed to bed.

The patient made a good recovery, although in consequence of her toxæmic condition we thought it advisable for three days more to give her nothing but soda and water. After delivery the urine rapidly improved both in quantity and quality, so that on the fourth day it was normal in colour and free from albumin.

Comments on Cases.

I have not reported these cases as exceptional, but, on the contrary, as being such as are generally met with in cases of severe accidental hæmorrhage. I believe that the detachment of the placenta and the hæmorrhage in such cases are caused by thrombosis of the veins of the placental site, probably due to toxæmia, and that the disease is the same as that which causes puerperal convulsions.

Those are the chief points that I wish to emphasise, but there are two others to which I shall allude. One is that in none of the cases was it necessary to remove the uterus—indeed, had I done so in the third I am certain she could not have recovered; and the other as regards dietary. It is generally believed that a milk diet is necessary in these cases, and there is no doubt that it is better than any other kind of food. But Dr. Tweedy maintains—and I agree with him—that water only is much better even than milk, and the fact, which I have noted in the third case, that serious aggravation of the patient's condition has followed the ingestion of even a small quantity of milk has been observed by us on several occasions. In answer to the question as to how long a patient can be restricted to water alone I would call attention to the fact that this woman had nothing, with the exception of 8 ounces of barley-water and milk, but soda and water for eight and possibly for ten days, and yet she recovered.

Dublin.

THE DIFFERENTIAL DIAGNOSIS OF AMOEBIC AND BACILLARY DYSENTERY FROM THE BLOOD.

BY G. MARSHALL FINDLAY, M.B., CH.B. EDIN.,
TEMPORARY SURGEON, R.N.

THE early, and at the same time correct, differentiation of amoebic and bacillary dysentery is a matter of very considerable importance from the point of view of treatment; for whereas in amoebic dysentery it may be possible to withhold emetine for a few days without any dire result, in bacillary dysentery it is certainly inadmissible to delay the administration of serum. Unfortunately, the present diagnostic methods of dysentery are by no means simple; they take up a considerable time, require a certain amount of skill, and presuppose the existence of a well-equipped laboratory. On active service these conditions are not always obtainable.

In the present paper an attempt has been made to arrive at a simple method of differential diagnosis from an examination of the blood alone. It must in the first place be remembered that the underlying pathology of amoebic and bacillary dysentery is absolutely dissimilar. The former condition is produced by the action of a protozoan which by means of a proteolytic enzyme sets up a colliquative necrosis of the tissues in its immediate vicinity, the latter condition is of the nature of a well-marked bacillary toxæmia.

Description of Tests.

In the differentiation of amoebic and bacillary types of dysentery the two following reactions have been used: (1) the iodine reaction in the polymorphonuclear leucocytes; (2) the production of nuclear pseudopodia in the polymorphonuclear leucocytes.

1. It has long been known that in certain pathological conditions the polymorphs, when treated with dilute iodine in dry blood films, give a glycogen reaction, but it is only recently that Bond¹ and others have shown that even in health a large proportion of the white blood corpuscles normally give under certain conditions a reaction with iodine which is closely related to the glycogen reaction met with in certain diseases. When normal white blood cells are incubated for a quarter of an hour at 37° C. and are subsequently treated with a 1 per cent. solution of iodine in water and potassium iodide a certain number of the white cells show the presence of one or more mauve-coloured droplets. These droplets gradually coalesce to form one large drop, which eventually breaks the lining membrane of the cell and escapes into the surrounding medium. The particular cells which show the presence of this iodophile substance are certain of the polymorph leucocytes. The actual technique for the demonstration of the iodine reaction is as follows:—

A drop of blood from the finger is placed in a Ponder's plasticine cell² and incubated for one hour at 37° C. During incubation the white blood corpuscles pass out from the clot and adhere to the cover-glass above and the slide beneath. The cover-glass and cell are then removed and the clot is washed away with normal saline. Two films of leucocytes are thus obtained, which are mounted in the 1 per cent. solution of iodine in potassium iodide. All the cells in contact with the iodine take on a yellowish tint, but, as before mentioned, certain of them show the presence of mauve globules in the protoplasm. In the normal individual the number of cells giving the reaction is roughly 50–60 per cent. Bond, however, has pointed out that in conditions associated with the presence of bacillary toxins in the blood the amount of iodophile substance is increased, as there is a large increase not only in the number of cells actually giving the reaction, but also in the amount of iodophile substance present in the individual cells. This increased iodine reaction persists in the blood for a fortnight or three weeks after the disappearance of the active symptoms of the disease. Applying the above reaction to the case of bacillary dysentery, it is found that the number of white cells giving the iodine reaction is 60–80 per cent., while the increase in the amount of iodophile substance is also well brought out. By this means, therefore, we have a method, with certain reservations, of determining whether the dysenteric infection is due to a bacillus or not. It is necessary, however, to exclude any recent septic infection, such as a sore-throat or whitlow, since such a condition produces a similar iodophile condition in the blood.

In one of the earliest cases examined—an amoebic infection—the blood gave a well-marked iodine reaction, a

phenomenon only explained when it was found that the patient had a suppurating venereal bubo in the groin.

In addition, in long-standing amoebic infections where there is secondary bacillary infection the blood may also give a well-marked iodine reaction.

2. The formation of nuclear pseudopodia. An examination of a large number of polymorph leucocytes derived from healthy individuals reveals the fact that in a very small percentage of cells the nuclei are furnished with finger-like processes, or pseudopodia. These processes are usually classified into three types: (1) pyriform; (2) blunt or sessile; (3) spiculated. The cause of the formation of these pseudopodia is at present unknown, except in so far as they appear to be due to active nitrogenous metabolism.

Gruner,³ who has studied their production, has found that they are produced by a purin-containing diet, while they are also numerous in carcinoma, except in those cases where the tumour is so circumscribed that the cancerous excreta cannot enter the blood stream. An examination of the blood films from cases of amoebic dysentery reveals the fact that in this condition also there is a large increase in the production of nuclear pseudopodia. This increase is noticeable on the second or third day of the disease. Thus in amoebic dysentery the percentage of polymorphs with pseudopodia was found to vary from 12.5 per cent. to 52 per cent., the average being 18 per cent., while in bacillary dysentery the percentage obtained varied from 0 to 11. Out of 50 cases of bacillary dysentery examined the percentage of polymorphs with nuclear pseudopodia was in no instance above 12. It is interesting to note that in two cases of liver abscess without any dysenteric symptoms the number of cells with nuclear pseudopodia was 25 per cent. and 27 per cent. respectively.

A very large number of blood films from various pathological conditions have been examined for the production of nuclear pseudopodia, with the result that the only other condition in which the change could be found was chronic tuberculosis of the lungs. Provided, therefore, that the patient is living on a purin-free diet and that it is possible to exclude cancer and pulmonary tuberculosis, the formation of nuclear pseudopodia in a case of dysentery is highly suggestive of an amoebic infection.

Conclusion.

Taken in conjunction, the two tests above described enable an accurate diagnosis of the type of dysentery to be given at an early stage of the disease in at least 90 per cent. of cases. The occurrence of a well-marked iodine reaction without the formation of nuclear pseudopodia is suggestive of a bacillary infection, while the absence of the iodine reaction and the presence of nuclear pseudopodia naturally point to an amoebic origin. Should a well-marked iodine reaction occur in conjunction with the formation of nuclear pseudopodia the possibility of a mixed infection should not be overlooked.

NASAL OBSTRUCTION IN AVIATORS.

By DOUGLAS GUTHRIE, M.D. EDIN., F.R.C.S. EDIN.,

CAPTAIN, ROYAL AIR FORCE; INTERIM SURGEON TO THE EAR
AND THROAT DEPARTMENT, ROYAL HOSPITAL FOR
SICK CHILDREN, EDINBURGH.

THE science of aeronautical medicine is still in its infancy. Researches pursued in various directions have proved that the successful pilot must possess a sound heart and sound lungs, a stable nervous system and a healthy "mentality."

Scarcely less important is the possession of good binocular vision and of normal ears. The ear-mechanism obviously becomes a more essential factor in flying when we remember to regard the ear not only as the organ of hearing but as an accessory organ of equilibration. Although the aviator depends mainly on his sense of vision it is, perhaps, a matter of regret that the sense of equilibration, a sense so highly developed in birds, and so readily accurately estimated in man by the Bárány tests, has received so little attention from those who have, in this country, studied the medical aspects of aviation. Into the rationale of those tests and their relationship to aviation I do not propose to enter in this short paper, but would merely refer to one aspect of the subject which is well worthy of notice—i.e., the question of nasal obstruction.

To the flying man free nasal respiration is an important asset. The statement will meet with general acceptance, though the reasoning on which it is based may not be so

widely understood. During the past few months I have had occasion to examine and operate upon a considerable number of officers and cadets suffering from nasal obstruction, and although I have followed the subsequent flying history in only a few instances certain interesting facts have come to light.

Results of Nasal Obstruction.

The main conclusions regarding the baneful effects of nasal obstruction on the aviator may be summarised as follows:—

1. *Effect on the lungs.*—The mouth-breather cannot satisfactorily expand his chest, and his lungs are never sufficiently aerated. Mendel has demonstrated experimentally the inferiority of respiration by the mouth and has shown that the amount of air which the mouth-breather inhales with each breath is less by one-fifth than the amount inhaled in normal nasal respiration. It follows, then, that if the subject be an aviator he will readily suffer from symptoms of "oxygen-want." This aspect of "oxygen-want" probably deserves further investigation.

2. *Effect of equilibration.*—The Eustachian tubes, the function of which is to adjust the pressure of air within the middle ear to the changes produced by sound-waves, atmospheric pressure, &c., and which come into use so largely during flying, are impaired in their function if any nasal obstruction is present. During a rapid descent the tympanic membranes are driven inwards by atmospheric pressure, causing deafness and earache. Normally those symptoms disappear if the ears are "inflated" by swallowing or by movement of the jaw. But if the nasal passages be blocked so that air does not freely reach the Eustachian tubes the alteration of pressure within the middle ear cannot be compensated and the symptoms persist, perhaps with the addition of giddiness caused by altered labyrinthine tension, communicated from middle to inner ear through the round and oval windows. Under such circumstances the risk of a crash is, naturally, considerable.

3. *"Reflex" effects.*—A third possible result of nasal obstruction is headache coming on in the air or after landing. This is in many cases due to the pressure of a deflected nasal septum against the middle turbinal, the so-called reflex nasal headache. Headache of this type is, of course, not peculiar to aviators, but is aggravated by flying for reasons to be presently described.

Causes of Nasal Obstruction.

The commoner causes of nasal obstruction are adenoids, hypertrophic rhinitis, and septal deviations.

Polypi were encountered on only one occasion in the present series. Adenoids were present in many cases, accompanied, as a rule, by enlarged and septic tonsils, but in few cases were the postnasal growths so large as to cause much nasal obstruction. They were, however, liable to attacks of inflammation, and then the Eustachian tube became blocked, not by adenoid tissue, but by the mucus and pus which that tissue secreted.

Hypertrophic rhinitis, affecting the anterior or posterior ends of the lower turbinal, was fairly common and was readily cured by partial turbinectomy.

Deformities of the nasal septum were the cause of the obstruction in the majority of cases. As a rule the patient gave a history of former injury at boxing or football. Some of those definitely traumatic cases had almost complete obstruction of both nostrils. In others the symptoms were nil, and the patient was unaware of any nasal trouble until he came before the examining board.

Aggravated cases of septal deformity naturally call for treatment before the subject can be passed as fit for flying, but the wisdom of operating on minor degrees of septal deviation in cadets is questionable. Absolute symmetry of the septum nasi is a rarity among civilised races, and an examination of over 2000 skulls has revealed deformity of the bony septum in 75 per cent. (Morell Mackenzie). At the same time it is to be noted that a degree of nasal obstruction which would cause little trouble on the ground may be very troublesome in the air. At heights over 7000 to 10,000 feet the mucous membrane of the nose becomes swollen and engorged, and any existing obstruction is thus greatly aggravated.

This is borne out by the following typical reply to an inquiry addressed to one of the patients: "Before the operation," he writes, "I was compelled, when flying, to breathe through my mouth; this was difficult to do and was irritating to the throat, especially when I flew a fast scout at heights over 8000 feet and in cold weather. The operation has cured

this trouble, and I have since flown at 12,000 feet and over with no difficulty whatever."

Treatment.

The treatment of the cases in question is a matter of some importance. The main object, from a military point of view, is to render the patient fit as rapidly as possible. To this end it is advisable to employ local anæsthesia for septum cases. A method which answers well is to pack both nasal cavities half an hour before operation with 10 per cent. cocaine, and at the same time give a hypodermic of morphine and atropine. The patient complains of little discomfort during the submucous resection, even if one has to gouge away part of the maxillary crest.

After-treatment consists in packing both sides with ribbon gauze wrung out of liquid paraffin, a dressing which adapts itself to the tissues and is easily removed on the following day. Treated in this way septum cases need remain in hospital for only a few days.

In conclusion, it may be remarked that while commercial aviation will naturally impose much less strain upon the pilot than "war" flying, nevertheless the medical problems of aeronautics should be studied more and more in the future, and it is only by attention to such minor details as those indicated above that knowledge can be advanced and tests standardised. Aviation can only be developed on a sound footing by the mutual researches of the designer, the mechanic, the pilot, and the doctor.

POST-INFLUENZAL HÆMOPTYSIS.

By HORACE WILSON, M.D., B.S. LOND., D.P.H.,
TUBERCULOSIS MEDICAL OFFICER AND ASSISTANT M.O.H., BOROUGH OF
SOUTHWARK; DEMONSTRATOR OF BACTERIOLOGY, PUBLIC HEALTH
LABORATORY, KING'S COLLEGE.

ATTENTION has been drawn to the occurrence of epistaxis and other hæmorrhages in the recent epidemic of influenza, and there has also been a large group of cases in which hæmoptysis occurs which may readily be mistaken for pulmonary tuberculosis. These cases are often puzzling and may lead to erroneous diagnosis, and have to be carefully differentiated from those cases which drift almost insensibly from influenza into acute pulmonary tuberculosis.

As a rule the hæmoptysis in influenzal cases commences towards the end of the illness, when there is slight cough, an increasing weight, and no great tendency to wasting. The sputum shows a bright red staining, and not the typical rusty tint of acute pneumonia. Pneumococci are the predominant organisms and tubercle bacilli are absent.

The characteristic physical signs are generally marked by their bilateral posterior distribution in the suprascapular areas, where breath sounds are faint and moist granular adventitious sounds are abundant, with no bronchial breathing and some bilateral impairment of the percussion note. The corresponding areas in front show little or no change, excepting some lack of resonance on percussion. The mid-area of the lungs posteriorly is fairly clear, but the bases show congestive crepitation on both sides.

The temperature for a time is irregular and fluctuating, and the pulse-rate not so rapid as would be the case in a tubercular bacillary toxæmia corresponding to similar physical signs.

Careful observation of these cases for a few weeks will show subsidence of physical signs and temperature, with increasing weight and improved general condition. If, therefore, with slight hæmoptysis the physical signs are bilateral and chiefly marked posteriorly it is well not to be too precipitate in diagnosing pulmonary tuberculosis, but to make frequent examinations of the chest and sputum while taking the general progress of the case into consideration. Many of these cases have proved to be pneumococcal and transient, and a hasty diagnosis of tuberculosis on the ground of hæmorrhage may cause considerable distress.

As regards the physical signs the converse also holds good, and monolateral anterior signs with hæmoptysis give rise to much more suspicion of early pulmonary tuberculosis, particularly with no regain of weight on convalescence, rapid pulse, and night sweats.

So many cases of each type have come under the writer's notice during the last 12 months that he hopes these notes taken from his cases may be some guide to others when diagnosis is doubtful.

NOTE ON

STAPHYLOCOCCUS AUREUS SEPTICÆMIA

AS A COMPLICATION OF INFLUENZA IN AN EPIDEMIC
IN MALTA.

By ADAM PATRICK, M.D. GLASC.,

TEMPORARY CAPTAIN, R.A.M.C.

With a Note by Colonel Sir A. GARROD, K.C.M.G., A.M.S.

IN the bacteriological examination of a number of cases of influenza and broncho-pneumonia which have come under treatment in military hospitals in Malta it has become increasingly apparent that in this epidemic a secondary infection with *Staphylococcus aureus* is a not infrequent and a very serious complication. Attention was first directed to this point by the post-mortem findings in the case of a soldier who died on July 5th.

After this condition was recognised it was seen that the cases in which *Staphylococcus aureus* was found were frequently those of a severe type of broncho-pneumonia, with characteristic symptoms. I am greatly indebted to Colonel Sir A. Garrod for the following note descriptive of cases of this type:—

Note on Symptomatology by Colonel Sir A. GARROD.

"In the present epidemic of influenza in Malta the cases have been, for the most part, of a mild character, but amongst them, as always, cases of broncho-pneumonia have occurred and a small proportion of deaths. In a number of cases there have been pulmonary troubles of a peculiar kind, such as I have not seen in previous epidemics. Such cases occurred chiefly in groups of men coming from special centres.

These patients present a well-defined clinical picture, unlike that of ordinary influenzal pneumonia. After the subsidence of a short primary fever the temperature rises again, and the condition of the sufferer suddenly becomes grave. He acquires a cyanotic tint, his breathing becomes shallow and very rapid, from 40 to 60 respirations per minute. He is anxious about his state at first and begs to be put out into the open air, but later he becomes apathetic, drowsy, and appears not to hear what is said to him. He may lapse into coma, with picking at the bedclothes, or may even develop a condition of coma-vigil. Delirium of a muttering kind, or even of more active form, usually preceded the onset of coma. On the other hand, some patients remain conscious and anxious throughout, convinced that they are going to die.

The pulse is rapid and the temperature high, reaching 104° F. in some cases, 105° in a few. The tongue is dry and covered with a thick brown fur, and its clearing is one of the earliest signs of improvement. The sputum is almost invariably rusty or pink during the attack, and in some cases there is definite hæmoptysis. The spleen is sometimes enlarged, but I fancy that this is an outcome of local conditions. The urine usually contains albumin, a trace to a dense cloud. The physical signs are scanty considering the conspicuous embarrassment of breathing. Large areas of impaired resonance or dullness, chiefly over the lower lobes behind, and scattered crepitations, and sometimes pleural friction are the usual signs. Bronchial breathing is not usually heard. The temperature may maintain an even high level or may fall suddenly with symptoms of collapse, only to rise again in a few hours. Death may occur during an attack of collapse, but more often is ushered in by steadily increasing dyspnoea with increasing cyanosis.

The whole clinical picture is that of gradual suffocation. The pulse seldom falls seriously before the approach of death unless there be an attack of collapse. The cases recall those rare examples of acute oedema of the lungs in children, and, as Professor Zammit first pointed out to us, general oedema of the lungs is found post mortem. In cases ending in recovery the temperature falls by somewhat rapid lysis commencing on the eighth or ninth day of the secondary fever. The rate of respiration falls gradually, the colour improves. In some cases the sputum remains rusty for some days after the temperature falls."

Bacteriological Examination of Sputum.

The sputum of 50 patients with influenzal broncho-pneumonia has been examined bacteriologically (Table I.) Nine of these 50 patients died, and *Staphylococcus aureus* had been found in the sputum of seven of them. The nine others who had shown staphylococcus recovered, though

TABLE I.—Organisms found in the Sputum of 50 Patients with Broncho-pneumonia.

| Organism. | Times found. | Organism. | Times found. |
|---------------------------------|--------------|---|--------------|
| Pneumococcus | 45 | Spirochæte (Vincent type) .. | 6 |
| Micrococcus catarrhalis .. | 22 | Gram-positive cocci (other than above) .. | 5 |
| Streptococcus | 21 | Yeast | 2 |
| Sarcina | 18 | <i>B. influenza</i> | 1 |
| <i>Staphylococcus aureus</i> .. | 18 | <i>B. septus</i> | 1 |
| Gram negative bacillus .. | 13 | | |

several had a severe attack. The amount of this organism grown from the sputum of the fatal cases varied, being sometimes a small growth mixed with other organisms, and once an abundant pure culture.

Post-mortem Findings.

The bodies of six of the nine patients who died, and also the bodies of five others in whose case the sputum had not been investigated, were examined post mortem. Of these 11, nine gave evidence of staphylococcus septicæmia. In the two other cases staphylococcus was obviously not the cause of death. The post-mortem findings may be summarised.

The lungs of the nine staphylococcus cases showed broncho-pneumonia, not always extensive, but there was widespread congestion and noticeable oedema. No considerable area of lung tissue was found pink and spongy. The oedema tended to affect not only the pneumonic portions of the lungs but also those parts which remained unconsolidated. A section of the lungs a watery, frothy, slightly blood-tinged fluid exuded on slight pressure. In one case the amount of this fluid was excessive, and the lungs weighed 50 oz. and 42½ oz. respectively.

The broncho-pneumonic areas were not densely consolidated, but the process had a special tendency to go on towards abscess formation, and four stages could be distinguished:—

1. Broncho-pneumonia present, but consolidation not very firm; lung dark brownish-red on section; cut surface smooth; exudation of slightly blood-stained watery fluid on pressure.
2. Surface of cut lobule coarsely granular, and slightly raised from surrounding area of lung, but not quite so dark in colour as in stage 1; exudation of oedematous fluid on pressure, but in addition appearance of beads of pus in the cut bronchioles.
3. Cut surface very distinctly raised and coarsely granular, with numerous miliary abscesses visible in the substance.
4. Lung tissue largely destroyed and lobule converted into a collection of abscesses separated by fibrous septa.

The distribution of these stages was lobular and a sharp line of demarcation could be made out between stages 1, 2, and 3 on the cut surface. The broncho-pneumonic process tended to involve especially the greater portion of the lower lobes, and the inner half of the upper lobes. The lower anterior edge of the lower lobe was nearly always spongy. In most of the cases the process had not progressed as far as the formation of visible abscesses. In six out of the nine there was no obvious evidence of pus, but abscesses were present in some part of the lungs in the three others.

Three cases showed empyema, from all of which *Staphylococcus aureus* was obtained in pure culture. In a case with double empyema smears of the pus showed pneumococci on one side and pneumococci and streptococci on the other, but the only growth on culture was of staphylococcus.

The spleen was generally enlarged, in one case weighing 14 oz. and in two others 13 oz. The substance, as a rule, was of normal consistence and appearance. In the case of a patient with well-developed abscesses in the left upper lobe it was small (2½ oz.), pale, and soft. Considerable oedema was sometimes observed in the liver. The condition of the other organs called for no remark.

Two other cases remain to be mentioned.

In one of these there was considerable abscess formation and oedema in both lungs and their general appearance resembled that of the staphylococcus cases, except that the consolidated areas were denser than in any of them. Very numerous pneumococci had been found in the sputum during life and after death extensive acute pleurisy was found, with un-mixed pneumococci in the fibrinous exudate. Pneumococcus, sometimes mixed with a Gram-negative bacillus, was grown from most of the organs. It was isolated in pure culture from the spleen. A few colonies of *Staphylococcus aureus* were grown from the right lung, but the pus formation and the septicæmia could not be attributed to it. This patient was already ill when he arrived on the island, and it was not certain, though probable, that he was suffering from influenza. Clinically he had been regarded as different from the staphylococcus cases.

In the other fatal case in which staphylococcus was not found the appearance of the lungs was quite different. There were about 2 oz. of pus in the left pleural cavity, and the lower lobe of each lung was deeply congested and in a state of splenisation. The distribution of the consolidation was lobular. The right upper and middle lobes and the left upper lobe were light pink in colour and showed no congestion or oedema. Streptococcus in pure culture was grown from the left lower lobe and streptococcus mixed with a few sarcinae from the right lower lobe and the empyema.

Table II. shows the result of cultures from organs in the 11 cases, and also whether *Staphylococcus aureus* had been found in the sputum during life.

In four cases in which it was estimated the leucocyte count was rather low—4000 (staphylococcus case), 7800, 6800 (staphylococcus case), and 6800 per c.mm. Blood cultures were taken from five patients and no growth resulted in any. One of these was made two days before death in a case in which staphylococcus was afterwards found in the heart blood.

Staphylococcus aureus is rather a rare organism in the respiratory tract, and in ordinary circumstances the tissues seem to have adequate powers of resisting it. It is not so

TABLE II.—Cultures from Organs in 11 Fatal Cases of Broncho-pneumonia.

| Organ. | Case. | | | | | | | | | | |

Organisms found in pure culture except where otherwise stated.

S. = *Staphylococcus aureus*. Str. = Streptococcus. Pn. = Pneumococcus. Sar. = Sarcina. Bac. = Gram-negative bacillus. — = No growth.

¹ Almost pure culture. ² Mixed with pneumococcus. ³ With a Gram-negative bacillus in small numbers. ⁴ With a few sarcinae. ⁵ With other organisms.

with some of these cases of influenza, in which the sequence of events emphasises the fact that when conditions are favourable to its dissemination throughout the body *Staphylococcus aureus* is an organism of great malignancy. The examination of the sputum in most cases of broncho-pneumonia gives little information, but the results of this short series show that in influenzal broncho-pneumonia it may be of some value in estimating the prognosis.

ON SOME SIMPLY PREPARED CULTURE MEDIA FOR *B. INFLUENZÆ*

WITH A NOTE REGARDING THE AGGLUTINATION REACTION OF SERA FROM PATIENTS SUFFERING FROM INFLUENZA TO THIS BACILLUS.

BY ALEXANDER FLEMING, F.R.C.S. ENG.,

TEMPORARY CAPTAIN, R.A.M.C.; HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS.

(From the Research Laboratory attached to a Base Hospital in France.)

THE traditional text-book method for the growth of *B. influenza* was agar to which a certain amount of fresh blood or blood corpuscles had been added. On such a medium *B. influenza* showed very tiny pin-point colonies sometimes very difficult to see with the naked eye. More recent investigations have shown that much more copious growths can be obtained when the added blood has been altered in various ways.

Fitzgerald and Cohen (*Centralblatt für Bacteriologie*, 1911) obtained greatly enhanced growths by heating the blood to 80°C. for three minutes.

Matthews (*THE LANCET*, July 27th, 1918) showed that very profuse growths occur when the blood has been digested with an excess of trypsin for five days at 37°C.

Levinthal (quoted in the October number of the "Medical Supplement to the Daily Review of the Foreign Press") obtained profuse cultures by adding blood to agar in the proportion of 1 to 20, then boiling and filtering the medium.

The object of the present communication is to emphasise the advantages of blood altered in various ways on the growth of *B. influenza* and to indicate certain very simply prepared media on which enormous growths can be obtained. The author has had the opportunity of seeing and making many cultures of *B. influenza* on agar with blood digested with trypsin, as for some years at St. Mary's Hospital all our *B. influenza* vaccine was made from cultures on this medium, and there is no doubt as to the wonderfully profuse growths which can be obtained from its use. The preparation of the medium is, however, cumbersome, as it takes four or five days for the trypsin to produce the necessary change in the blood. It is thus impracticable to use such a medium if it is desired to make cultures of *B. influenza* without previous warning unless a stock of the medium is kept on hand. It also requires sterile blood and sterile trypsin, which are not always to hand. It would be of considerable advantage, therefore, if the same profuse growth could be obtained on a medium which could be prepared on the spur of the moment and which did not necessitate the use of materials not readily obtainable. The following observations show that this can be done.

Blood boiled in agar.—If blood is added to a tube of agar and boiled for one minute the whole of the colouring matter of the blood and the coagulable proteid is precipitated in masses. The tube can then be sloped, and before the agar cools sufficiently to become solid the whole of this precipitate will have settled to the bottom, leaving the upper part of the medium clear. If *B. influenza* is planted on this an enormous growth results. The same result is obtained if blood corpuscles only are used.

The amount of blood which it is necessary to add is indicated in Table I.

TABLE I.—Blood added to 5 c.cm. agar, boiled, cooled, and planted with *B. influenza*.

| Amount of blood added. | Resultant growth. |
|------------------------|---|
| 0.25 c.cm. | Copious confluent growth. |
| 0.12 " | " " " (not quite so heavy). |
| 0.06 " | " " " (colonies like streptococcus). |
| 0.03 " | " " " (colonies small and growth scanty). |
| 0.01 " | " " " (colonies small and growth scanty). |
| 0.005 " | No visible growth. |

Blood boiled with water and the resultant fluid added to agar.—If 1 c.cm. of blood is boiled with 9 c.cm. water the whole of the colouring matter of the blood and the coagulable proteid is precipitated in masses which rapidly separate, leaving a clear, colourless, watery fluid.

It may be necessary to add a small amount of acetic acid to get complete precipitation, but the amount of acid added should not be enough to neutralise the alkalinity of the blood. It is not material to the growth of *B. influenza* whether the liquor obtained is clear or whether it contains debris of altered blood. Clear fluid has, however, the advantage that it gives a transparent medium indistinguishable in appearance from ordinary nutrient agar.

This fluid is added to liquid nutrient agar and sloped. On planting with *B. influenza* a very profuse growth takes place.

The following experiment (Table II.) shows the quantity of this fluid which it is necessary to add to 5 c.cm. of agar.

TABLE II.

| Quantity of fluid added. | Corresponding to original blood volume of— | Resultant growth. |
|--------------------------|--|---------------------------|
| 1 c.cm. | 0.1 c.cm. | Copious confluent growth. |
| 0.5 " | 0.05 " | " " " |
| 0.25 " | 0.025 " | Copious colonies (small). |
| 0.12 " | 0.012 " | No growth. |

The whole of the coloured fraction of the hæmoglobin is precipitated from the blood by boiling and only a colourless watery fluid is added to the agar. It is clear, therefore, that whatever is the nature of the substance which favours the growth of *B. influenza*, it is not, as was generally supposed, the coloured element of hæmoglobin.

Blood broken down by acids.—If to blood is added an equal volume of a normal solution of one of the strong mineral acids, such as sulphuric acid, the red colour is immediately changed to brown by the breaking down of the hæmoglobin. If now an equivalent volume of normal caustic soda is added, a brown precipitate is formed and a brownish fluid separates.

It is important to test the reaction of the fluid after the addition of the caustic soda to see that the reaction is only faintly alkaline to litmus as a small error in the quantities of acid or alkali of this strength makes an enormous difference to the reaction of the medium, and consequently to the growth of the bacillus.

If this fluid is added to liquid agar it furnishes a medium on which the most profuse cultures of *B. influenza* can be obtained. It would appear, therefore, that so far as the growth of *B. influenza* is concerned sulphuric acid will effect the same change in blood in less than one minute that it takes trypsin four or five days to produce.

The quantities of fluid necessary to add to 5 c.cm. of agar are shown in Table III.

TABLE III.

| Quantity of fluid added. | Corresponding to original blood volume of— | Resultant growth. |
|--------------------------|--|-----------------------------------|
| 1 c.cm. | 0.1 c.cm. | Copious confluent growth. |
| 0.5 " | 0.05 " | " " " |
| 0.25 " | 0.025 " | " " " (not quite so heavy). |
| 0.1 " | 0.01 " | Copious growth of small colonies. |

The best proportions in which to mix the fluids seem to be as follows: Blood, 1 part; water, 5 parts; normal sulphuric acid, 1 part. This mixture can be boiled and stored at room temperature for some weeks without deterioration.

This medium, which certainly gives as copious growths of *B. influenza* as any other, is very easy to prepare, and it has the additional advantage that it does not require sterile blood. The sulphuric acid is a very powerful antiseptic and rapidly

sterilises the blood, even if it is very badly contaminated. This is brought out in the following experiment.

1 c.cm. of blood was added to 5 c.cm. of tap water and the mixture was then heavily contaminated with faeces. 1 c.cm. of normal sulphuric acid was then added, and the tube, after being shaken, was left at room temperature for half an hour, when 1 c.cm. of normal caustic soda was added. Of the resultant fluid 1 c.cm. was added to liquid agar, sloped, planted with *B. influenza* and incubated at 37° C. An extremely copious growth of *B. influenza* resulted, the medium being otherwise sterile.

It has been found that on media prepared from blood altered in these ways other organisms, such as staphylococci, do not exercise any symbiotic action on the growth of *B. influenza*. It would appear, therefore, that the change produced in the blood by boiling or by strong acids is of a similar nature to that effected by these organisms which exercise such a powerful symbiotic effect on *B. influenza* when unaltered blood is used.

Agglutination of *B. influenza* by serum of men suffering from influenza.—From the media described above very good emulsions of the bacillus can be obtained for agglutination purposes.

The sera of 21 patients suffering from influenza were examined for agglutinins to *B. influenza*. Wright capillary tube method was used, and the tubes were incubated at 50° C. for two hours before readings were made. The results were as follows:—1 serum agglutinated the bacillus up to a dilution of 1 in 1000; 2 sera up to 1 in 128; 3 sera up to 1 in 64; 10 sera up to 1 in 32; 4 sera up to 1 in 16; and 1 serum up to 1 in 8.

The duration of the disease in these men had been from three days to three weeks, but most of them were convalescents about seven to ten days after the onset. It will be seen that all the patients' sera agglutinated *B. influenza* to some extent, whereas none of the control sera tested showed any agglutination even in a 1 in 4 dilution. It follows from this that *B. influenza* is either the cause of the disease, or it is an extremely common secondary infection, and if it is a secondary infection then it follows the primary infection very rapidly, as agglutinins had developed in one case only three days after the onset.¹

A differential medium for isolating *B. influenza*.—It has long been known that certain dyes, among them brilliant green, had the power of inhibiting the growth of Gram-positive bacteria to a very much greater extent than Gram-negative bacteria. It was thought that possibly, now we have a medium which grows *B. influenza* luxuriantly, the addition of a small amount of brilliant green to the medium might allow the growth of this bacillus while inhibiting the growth of the cocci which commonly exist in the sputum.

Agar was made up containing some of the clear fluid obtained by boiling blood and water, and to this was added brilliant green in a strength of 1 in 500,000. On this was planted *B. influenza*, staphylococci, streptococci, and pneumococci. After incubation a profuse culture of *B. influenza* was obtained, whereas all the cocci were completely inhibited. I suggest, therefore, that such a medium might prove extremely valuable in isolating *B. influenza* from a sputum where it occurs, as it commonly does, mixed with streptococci or pneumococci.

A medium for preserving the vitality of *B. influenza*.—In certain quarters there has been difficulty in preserving alive cultures of *B. influenza*.

If this bacillus is planted into minced meat medium such as is commonly used for growing anaerobes to which a little blood has been added, it will preserve its vitality for a considerable period. Subcultures from this medium after six weeks gave growths as copious as after two days.

Summary.—Very profuse growths of *B. influenza* can be obtained (1) from blood boiled in agar; (2) from agar to which has been added some of the clear colourless fluid resulting from boiling blood in water; (3) from agar to which has been added blood which has been broken down by a strong mineral acid. If a strong mineral acid is used to break down the blood sterile blood is not required. The substance which stimulates the growth of *B. influenza* is not the coloured fraction of hæmoglobin.

By the addition of brilliant green to the medium pneumococci, streptococci, and staphylococci are inhibited to a much greater extent than is *B. influenza*.

Cultures of *B. influenza* can be kept alive for a considerable period on a blood meat medium.

All the patients tested who were suffering from influenza agglutinated *B. influenza*.

¹ Further work in this direction has shown that different strains of *B. influenza* differ markedly in their agglutination reactions. Some strains were readily agglutinated by patients' sera, while others were unaffected. The serum of a rabbit inoculated with one strain agglutinated only this strain and one other out of 20 different cultures tested.

Clinical Notes : MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF CANCER OF THE CÆCUM WITH PELVIC ABSCESS AND GANGRENE OF RECTUM.

BY J. K. HAWORTH, M.D., B.S. DURH.,
CAPTAIN, R.A.M.C.(S.R.); SURGICAL SPECIALIST, 8TH (LUCKNOW) DIVISION.

THE following case may be of interest.

Private D., age 46, was admitted from the medical ward, Station Hospital, Lucknow, with a large sinus discharging faeces and pus about $\frac{1}{2}$ inch to right of anus and communicating with the anus. Patient had been ailing with hectic temperature and general debility and loss of weight for some weeks before reporting sick. Abdomen flaccid and nothing palpable. The only physical signs were the sinus and the marked debility.

An operation was performed on July 26th. The sinus was explored and found to lead to a large abscess cavity in the pelvis in which the lower end of the rectum was almost free, friable, and gangrenous. A large tube was inserted. The patient died some hours later. At the post-mortem examination a large soft, fungating cancer was found in the cæcum. In the pelvis was a large abscess cavity with rectum sloughing and gangrenous in it. The growth was causing no obstruction.

The explanation appears to be that the glands in front of the sacrum had suppurated and the pus tracked down the rectum, opening into it and involving it, and finally finding exit near the anus wall.

A CASE OF ECTOPIC GESTATION WITH AN APPARENTLY IMPERFORATE HYMEN.

BY S. G. PAPADOPOULOS, M.B., B.S. LOND.,
M.R.C.S., L.R.C.P. LOND.,
RESIDENT SURGICAL OFFICER IN CHARGE OF SURGICAL OUT-PATIENT
DEPARTMENT, THE MILLER GENERAL HOSPITAL FOR SOUTH-EAST
LONDON, GREENWICH-ROAD, S.E.

AN ectopic gestation is a fairly uncommon condition, and a hymen which at the time of the operation is imperforate is also rare. A combination of the two makes the case so out of the common that I consider it worth publishing.

The patient, a young woman of 28, married 6 months, was admitted on August 19th, 1918, with a history that on the 5th of that month she was taken suddenly ill with a severe attack of abdominal pain, that she soon became faint, and very pale. Her usual medical attendant was called in who ordered her to bed for a week. On August 11th she first lost blood and as she was getting worse she was sent to this hospital. She also stated that she never had any discharge per vagina, but that she used to menstruate once every 33 days. During the last two months she had not done so.

On examination she was very pale, pulse 98, temperature 99° F. There was a large swelling at the left iliac region; the abdomen was rigid and tender on palpation. The vulva appeared normal. The hymen was unruptured and very resistant, and at that time one could find with difficulty a tiny aperture permitting the entrance of a fine probe, from which a dark, tar-like fluid was exuding. The vagina was patent, for on pushing the hymen with the finger one could invaginate it and the lower end of the vagina upward like an inverted glove.

I performed laparotomy shortly afterwards. There was free blood in the peritoneal cavity and large pieces of blood-clot were surrounding an enlarged uterus, the size of a two months pregnancy. These clots were swabbed out, and the Fallopian tube (left), which was very enlarged, was found imbedded in the organised clot. The whole mass was adherent on the rectum and anteriorly in the utero-vesical pouch, which was carefully separated. From the nature of the adhesions it seems that gestation continued after the Fallopian tube was ruptured and the fetal sac ruptured later. The left ovary was also imbedded in the mass and the whole Fallopian tube, sac, clot, and ovary, were removed, and the stump firmly tied in the usual way. The patient made an uninterrupted recovery.

On Sept. 13th a plastic operation was performed on the vulva. On examination of the hymen, under anæsthetic, it was found that it formed a complete septum, completely closing the vagina without any signs of aperture or even scar! I therefore pinched it at its middle with toothed forceps and cut a small opening into it. A little tar-like fluid escaped, and with the finger it was found that the vagina was normal, and therefore the considerably thickened membrane was removed with scissors and the raw edge stitched by a continuous catgut suture leaving a normal-sized canal. The patient is now completely well and back to her domestic duties.

There is no doubt that the menstrual flow was delayed in the vagina each time until the pressure produced temporarily a little puncture through which fluid could escape, and that conception took place at one of these periods. From the condition of the hymen it is obvious that no proper sexual intercourse could have taken place, but in spite of that abnormal pregnancy occurred.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

The Management of Venereal Diseases in Egypt during the War.

A GENERAL meeting of Fellows was held on Jan. 20th, when an illustrated lecture was delivered by Sir JAMES W. BARRETT, Lieut.-Colonel, R.A.M.C., on his own experience in the management of venereal diseases in Egypt during the recent war. Sir JAMES GALLOWAY occupied the chair.

Commencing with a brief reference to the history of venereal diseases in Australia prior to the war, Sir JAMES BARRETT stated that efforts to combat these diseases began in 1896 and culminated in 1910 with an investigation made by the Government at Melbourne. The results of this were so impressive that clinics were established, an educational campaign instituted, and, probably for the first time, newspapers opened their columns to communications on the subject, couched in technical terms. Little result followed this early effort, and a committee was then formed to work out the details of prophylaxis, while pressure was brought on the leading chemists of the city to place calomel ointment on sale for this purpose. Ministers of State and ministers of religion were approached for their support, but many of the latter did not approve of the steps proposed. It was, however, arranged for a committee of clergy to be taken to the asylums to see cases of general paralysis and locomotor ataxia, to visit hospitals and clinics, and further work in this direction was contemplated when war broke out and the lecturer left for Egypt. On his way thither Sir James Barrett gave lectures to the men on the value of continence, pointing out that if determined to expose themselves to infection they must take precautionary steps. In January, 1915, venereal diseases were very prevalent in Egypt, and the military authorities were keenly anxious about the health of the troops. The troops were then occupying the Delta, and here it was that the diseases were contracted. Afterwards when the Army reached Gaza, and in 1917 when the Turkish lines were broken through, a new problem arose with the appearance of considerable numbers of new infections. The lecturer held that trouble might have been expected in the case of troops coming from a dominion where discipline was not pronounced and thrown into an Eastern country like Egypt and surrounded by every inducement to sexual intercourse, natural and unnatural. When the break-through occurred in Palestine venereal diseases were more easily kept under control, the lines of communication being then 600 or 700 miles long. Here the lecturer interpolated the remark that the military campaign was in essence a fight against malaria, an enemy which had previously arrested Mark Antony, hindered Trajan, destroyed the Crusaders, and impeded Napoleon.

The Measures Adopted and their Results.

Sir James Barrett on his arrival in Egypt was invited by General Birdwood to do anything he could for the Australian troops, who were being infected at the rate of 800 or 1000 men a day, social and moral measures alone being permitted. He visited every ship arriving in port, the men being forbidden to leave until he came on board. A leaflet of advice was handed to each man warning against the perils of native alcohol and of exposing themselves to venereal infection, and the position was fully explained to the officers without going into the question of prophylaxis. In the hospitals, on the other hand, besides enlightening literature, the men were provided with prophylactic outfits consisting of calomel ointment. On the value of prophylaxis being challenged, an examination of those Australian troops who had been supplied with outfits established the fact that out of a group of 200 men exposed to infection only one contracted disease, and he had not taken precautions. In the lecturer's experience primary prophylaxis had been practically certain in its results. But, at the same time, Sir James Barrett emphasised his view that no educational opportunity should be neglected. He showed pictures illustrating the huts and converted buildings used as social and athletic clubs for the troops in order to provide counter attractions. All this had been done in association with the Y.M.C.A., which had performed invaluable work in following the men high up to the front line and erecting huts there for their comfort and

diversion, and organising clubs. Social advantages were thus kept close to the men during the whole of their advance. During the latter half of 1915 Sir James Barrett was invalided for a time to England, and there was a period when the work was not pushed, but the result was that an intense moral and restrictive campaign, together with constructive work in the establishment of magnificent soldiers' clubs, produced a moderate amelioration and tolerable decency. But where prophylaxis was properly taught and applied venereal diseases were practically non-existent. At the end of 1915 the men returned from Gallipoli and moved to France, when infections became more numerous. The Australian troops returning from the Dardanelles in the first five months of 1916 included 10,000 with venereal infections, and at one time the average infection rate was 25 per cent. per annum. After the adoption of measures which included penal measures against unnatural offences, public indecency and pimping, the control of advertisements, the restriction of the sale of alcohol, the strict medical examination of prostitutes, the provision of ablution rooms, and the supply of prophylactics, the infection rate became reduced to very modest proportions. On the march into Palestine the moral and prophylactic campaigns were combined, and in the latter half of 1918 the disease was checked. Whilst these events were taking place throughout Egypt, at Port Said martial law was proclaimed by Lieutenant-Colonel Elgood, and prostitutes were excluded from European quarters. The women who would not leave Port Said were confined to the Arab quarter, under the Egyptian Public Health Department. An end was put to the white slave traffic discovered by the censor, and the women were examined. But soldiers still became infected from women who were reported free of disease.

Whatever the measures taken, the disease could not be stopped altogether, and so long as intercourse took place without precautions venereal diseases would necessarily result. But the value of prophylaxis emerged. In one camp through which 9282 troops passed 4500 men reported exposure to infection, and as a consequence of early preventive treatment only 13 infections resulted. The lesson taught by experience in Egypt was that all social methods combined resulted only in a limited reduction in the incidence of venereal diseases, and that unless some form of prophylaxis was adopted many infections were certain to result. From the establishment of venereal centres in this country Sir James Barrett anticipated nothing but good. The ethical side of the problem, so far as it concerned medical men, was the wholesale infection of the innocent, and Sir James Barrett could see no immorality in the prevention of venereal diseases by prophylaxis, or any value in a morality dependent upon the fear of consequences. If normal desire was to be satisfied marriage must not be postponed until the summer of life, or irregular unions would be formed. The matter, the lecturer concluded, lay largely in the hands of women; if they revised their standards of value and did not observe the existing and artificial social assessments, much of the existing sexual problem would speedily be solved.

Discussion.

Dr. OTTO MAY, who was in general agreement with the remarks of the lecturer, pointed out that at the present time we were concerned less with the actual restriction of the disease in the Army than with the evil among the civilian population. The danger of demobilisation was now generally recognised, and the Local Government Board was planning the establishment of a large number of treatment centres. He hoped that each county council and each county borough council would establish a full-time venereal clinic open day and night and every day, and that provision for early preventive treatment would be established at these clinics. In theory this solution of the problem was admirable, provided people could be induced to attend there for early treatment. In practice, however, it was a failure, for it would take almost a year before the clinics could be in working order. There was also the difficulty of providing an adequate staff. But even if every town had a clinic we should be a long way from solving the problem, because people would not go immediately after connexion for early treatment. The only reasonable alternative was to authorise the distribution of prophylactic outfits. The sale of drugs for this purpose was now illegal, save under the advice of a medical man, and Dr. May suggested that the Local Government Board or its successor,

the Ministry of Health, should make this question its own particular subject. The disease would not be wiped out altogether by the use of prophylactics, but that was no excuse for passivity, and there could be little doubt that a great diminution would follow if these steps were taken promptly.

Professor J. G. ADAMI paid a tribute to the work of Sir James Barrett, which had, he said, exerted a profound influence in America and Canada.

Sir JAMES GALLOWAY laid stress on the present difficulty of getting a complete staff for venereal clinics; there were not sufficient trained pathologists and bacteriologists available. The question of proper remuneration also demanded consideration.

Professor ADAMI suggested that non-commissioned officers of the R.A.M.C. might be employed to give instruction at the centres under the supervision of a medical man.

In replying, Sir JAMES BARRETT said that a forceful and intelligent presentation of the case to the public was necessary before it could be induced to spend money on the prevention of disease.

LONDON ASSOCIATION OF MEDICAL WOMEN.

The Future of the Medical Profession.

A MEETING of this association was held on Jan. 14th at 11, Chandos-street, Lady BARRETT, the President, in the chair.

Dr. JANE WALKER opened the discussion with a paper on "A State Medical Service," in which she referred to the need for a Ministry of Health, with the medical profession organised into a whole-time salaried service on the lines of the higher branches of the Civil Service, but admitted that there would be a transition stage with some part-time and some whole-time workers. Dr. Walker then drew attention to some of the well-known disadvantages of general practice as it is now conducted—the uncertain hours, the difficulty of making a sufficient number of visits in many cases of illness, the powerlessness of the profession in dealing with such evils as bad housing and the inroads made lately upon general practice, as in the treatment of tuberculosis and venereal diseases, and in maternity and child welfare. In a State Medical Service provision would be made for full hospital opportunity for all patients, for study leave every five to seven years, and for each medical officer to rise according to his merits and in the direction in which his talents lay. The medical profession was now too great to acquiesce in the plan whereby each man and woman competed with his neighbour; it should organise itself so as to ensure the greatest public welfare.

Dr. CHRISTINE MURRELL spoke on the position of the general practitioner in domiciliary treatment as a link between consultants, and to the advantageous position which he sometimes has over the medical officer of health in dealing with such evils as slum property. She referred to the conduct of American clinics on a collective system, in which treatment was open to all, with payments according to means, and assessed by almoners.

Dr. JESSIE CAMPBELL spoke on methods by which the standard of work in general practice might be raised. She advocated part-time appointments for such work as infant welfare, school treatment centres, and the treatment of tuberculosis and venereal disease. This would keep the general practitioner more up-to-date than attending post-graduate courses.

Dr. DOROTHY HARE said that the standard of work in general practice dropped because practitioners worked alone, and so lost mental stimulus, and that they found it difficult to try new treatment owing to want of moral support such as they would have in a hospital.

An interesting discussion ensued in which the following took part: Dr. RUTH BENSUSAN-BUTT, Dr. DICKENSON BERRY, Dr. M. COCKERELL, Dr. O. LEWIN, Dr. MEAKIN HERFORD, Dr. L. FAIRFIELD, and Lady BARRETT.

At the last meeting of the Edinburgh University Court, Dr. Dawson Turner was appointed additional examiner in medical physics.

LITERARY INTELLIGENCE.—P. Blakiston's Son and Co., Philadelphia, announce a second and revised edition of the American Red Cross Text-book on First Aid, by Colonel Charles Lynch, U.S.M.C.

Reviews and Notices of Books.

The Soldier's Heart and the Effort Syndrome. By THOMAS LEWIS, M.D. Lond. London: Shaw and Sons. 1918. Pp. 144. 7s. 6d.

INTO this small book Dr. Lewis has packed much information. As is his wont, he writes only of those things he has himself found to be true, and he sets these down in a well-knit form easy to apprehend. His experience of cardiac disabilities in soldiers is probably unrivalled, and this book is therefore one which no one handling these problems can afford to do without. It is written especially to help members of invaliding and pensions boards, and this purpose is admirably fulfilled.

Dr. Lewis's main thesis is that the "soldier's heart" syndrome is made up of the same subjective and objective components as follow strenuous exercise in healthy men. In the exhausted soldier, however, the point of cardiac distress is much more easily reached. For its causation this exhaustion depends on several factors, some inherent, some acquired. It is to be detected mainly by testing the man with physical exercises. These, if graduated, constitute a means of prognosis as well as of treatment. They are also applicable to the recruiting problem. These arguments, with tabulated results of the treatment based thereon, and much sound advice as to the discernment of organic heart disease, constitute the bulk of the book. It appears at an opportune moment, for one of the great tasks which the Pensions Medical Service (if and when we have one) must tackle is that of assessing fairly the claims of the man with a cardiac disorder or lesion. The book is clearly printed, and can be read in two or three evenings.

LIBRARY TABLE.

Kala-azar, its Diagnosis and Treatment. By ERNEST MUIR, M.D. Edin., F.R.C.S. Edin. London and Calcutta: Butterworth and Co. 1918. Pp. 38. Rs. 2.—This little book is introduced by Sir Leonard Rogers, and is written with the object of supplying to the medical practitioners in small towns and villages in India a guide to the diagnosis and treatment of this very prevalent disease. Until lately kala-azar was almost always fatal, but Dr. Muir considers that if the condition be treated by the intravenous injection of soluble antimony salts, as advocated by Sir Leonard Rogers, "recovery may be expected in almost all cases where the treatment is begun in time and carried out efficiently." Having considered the question of diagnosis, the author describes his method of treatment, which he divides into four divisions: (1) the production of leucocytosis by the intramuscular injection of turpentine, camphor, creosote, and olive oil; (2) the destruction of parasites by antimony salts; (3) the treatment of complications; and (4) general tonic treatment. The work should be useful to those who are actively engaged in dealing with kala-azar, as the technique of various operations, such as spleen puncture and the intravenous injection of antimony, are described in detail.

At Home in the War. By G. S. STREET. London: Heinemann. 3s. 6d.—The normal psychological attitude displayed towards the war, as it went on, by middle-aged men averagely endowed for comprehension and sympathy is probably a fair definition of the thing which Mr. Street was trying to express in this little book. He has been misled by his modesty if he thinks that his description of such an attitude represents the average man's ability. Such remarks as this: "It is a universal foible of humanity to exaggerate the work of what you know and another man does not know; the vanity of special knowledge is seen everywhere"; or the analysis of the anti-national spirit in the paper entitled "Our Intellectuals," are in their neat and terse manner expressions of what most of us would be proud to say half as well. The "Revanche" for middle age, in the paper called "The War and Age," is a specimen of the author's pleasant humour. On page after page one finds set out with lightness and charm some thoughts of which most middle-aged men at home have been conscious without being able to define them. Mr. Street holds up to many of us a mirror from which the haze obscuring our real thoughts has been skilfully wiped away. Many quite conscious of an imperfect realisation of

what is really being thought will value the little book and feel thankful and friendly towards its author. In a somewhat different vein to most of the book is an "essay in little," called "The War and Kensington Gardens," which Mr. Street says should have been really a sonnet or sonnet sequence. It would be pleasant if the author would try his hand in that mode; he has not only the deftness and delicacy but also the power which make up the true sonneteer.

A Health Reader for Girls. By AGNES L. STENHOUSE and E. STENHOUSE, B.Sc. Lond. London: Macmillan and Co., Limited. 1918. Pp. 190. 3s.—This is an excellent little book in which the subject of health is dealt with in the simplest language. The body is first described, after which an account is given of food, digestion, care of the teeth and cleanliness, clothing, breathing, ventilation, the blood, the nervous system, and special senses. The only chapter to which we take exception is that on the Food of Babies. Milk is not necessarily sterile after being stood in a pan of boiling water for a quarter of an hour. The information given on preparing the baby's food, on the amounts which should be given, and on the times of feeding is long out of date. No special dilution and no definite amount of food is now given to a baby of a certain age, and, though these instructions may be useful in helping to prevent disasters, it is a mistake to put a hard-and-fast rule on record in a book which may be referred to in the home, or to give a mother the idea that her baby can be fed by any rule-of-thumb method. Babies' digestions, like babies themselves, are not all made on one pattern.

New Inventions.

A "DROPPED-FOOT" APPLIANCE.

We have received from Mr. Frank Jenner, surgical boot-maker, Christchurch-road, Boscombe, an appliance intended to enable the sufferer from "dropped foot" to walk with ease and comfort. It consists of an iron framework formed of two sickle-shaped arms joined together at the straight ends by a short transverse bar passing under the sole of the boot and close to the heel, to which it is affixed by a flat broad hook. The straight parts of the sickle-shaped sides pass upwards towards the ankles, the bend in

the sickle allowing for the protrusion of the malleoli. The framework is kept rigid and in place by a strap passing round the back of the boot. The free ends of the framework are joined to the front part of the boot by spiral springs at points at either side of and at a level with the bottom of the

laced opening. These springs can be adjusted so as to correct any tendency to inversion of the foot or the opposite, and the whole apparatus can be adapted to any sized boot. The appliance, which costs 15s., is ingenious and may prove useful in practice—we are informed that it has been used with satisfaction at the Boscombe Military Hospital—but it seems to us that the upper portion of the lever is too short, consisting as it does only of the part corresponding to the last inch of the tibia and that the pressure of the strap over the tendo Achillis can hardly fail to be excessive if the device is to keep the toe from dropping. The hooks, too, by which the springs are connected with the boot do not seem very well adapted for hard wear. These criticisms, if in practice they are found to be just, can be readily met.

THE LANCET.

LONDON: SATURDAY, JANUARY 25, 1919.

The Psychopathic Criminal.

AMONGST the problems to which the war has given a new aspect and an added urgency the treatment of the mentally defective and unstable criminal is one of considerable importance. Large numbers of men will be returning to this country or will be coming out of the military hospitals while still suffering in some degree from mental and nervous disabilities brought about by the unexampled stresses of modern warfare. It may be anticipated with a fair measure of assurance that in many cases the mental enfeeblement of these invalids will be manifested by disorders of conduct of more or less gravity, bringing them into conflict with the law; and several instances of this kind have, in fact, come before the criminal courts within the last few weeks. Public opinion will not tolerate the treatment of these war victims by the indiscriminate methods which have been applied to the general mass of law-breakers. The demand will certainly be made that in every such case full consideration should be given to the mental condition of the offender, and that he shall be dealt with on curative lines adapted to his individual needs, and not merely by the stereotyped punitive and repressive measures which up to the present have been the sole resource of the law. To satisfy this demand, which can obviously be urged with no less force in regard to other categories of psychopathic delinquents, it will be necessary to introduce an entirely new spirit into the system of procedure in criminal cases and to recognise to a far greater extent than in the past the importance of the help which the expert in morbid psychology can give in the administration of justice.

A proof of public opinion in this direction is supplied by the proposals in a report which was submitted to a meeting of the justices of the City of Birmingham on Jan. 2nd of this year by their General Purposes Committee. This report, presented by Mr. GERALD BEESLY, deputy chairman of the justices, voices the dissatisfaction which has been felt by the Birmingham magistrates—a dissatisfaction which has doubtless been shared by magistrates in other parts of the country as well—at being compelled to deal with criminal cases without having any regular facilities for obtaining expert advice touching the mental condition of the offenders, and without adequate means of giving effect to such advice even if it were obtainable. In the opinion of the committee, this deficiency in the legal machinery has been an important factor in the relative failure of the existing penal system as a reforming agency and as a preventive of recidivism. With a view to organising a more satisfactory method of treatment the committee have put forward a number of

valuable suggestions, which they divide into two categories—those which are immediately practicable, and those which can only be carried out by special legislation. Of the proposals under the former heading the most important is the recommendation that a physician with expert knowledge of psychiatry should be attached to the court, with whom the justices can confer and take counsel in any particular case. It is interesting to note, as bearing on this suggestion, that a similar system was introduced in 1914 at the instance of Chief Justice HARRY OLSON, in connexion with the Municipal Court of Chicago. Here a psychopathic laboratory was instituted under the direction of Dr. W. J. HICKSON, for the examination of accused persons presenting indications suggestive of mental abnormality; and according to the recent reports of the Court (Tenth and Eleventh Annual Reports of the Municipal Court of Chicago) the results obtained have been such as to convince the judicial authorities of the practical utility of psychiatric assistance, not only in deciding as to the treatment of offenders but also, in many cases, in assessing the reliability of witnesses. It is difficult to think of Chicago as a field for the propagation of academic theories and doctrinaire views; and the fact that the authorities of this typically business centre have been moved by scientific psychology to consider the proper treatment of the criminal justifies the attachment of considerable weight to such testimony to the value of psychiatry in the administration of the law. The example of Chicago should encourage the citizens of Birmingham to carry out the interesting experiment which they have projected. They will, of course, be impeded in this enterprise by the fact that, in the present state of the law, only very limited means exist for applying differential treatment to the various categories of mentally defective and unstable offenders; but the accumulation of definite data regarding the relation of mental abnormality to crime, which this scheme should provide within a short time, will in itself be of considerable value in educating public opinion, and will do much to further the adoption of the legislative reforms which they advocate.

These reforms are set out in Mr. BEESLY's report as follows:—

1. The provision of "places of detention" for observation of cases of mental instability, instead of prison on remand.
2. The provision of farm colonies and the like for cases which cannot be dealt with under the Lunacy or Mental Deficiency Acts, instead of prison.
3. The establishment of a consultative clinic, associated with the administration of justice, with expert medical practitioner and lady superintendent in charge, for voluntary treatment of cases where some form of mental weakness is exhibited, and to which the friends or relations of the person affected might appeal for help and guidance.
4. The clinic might also: (a) Assist in determining how far more or less recidivist criminals submitted for examination by the police are fit to be at large; (b) examine persons suffering from "borderland insanity," whether submitted by public authorities or by their relatives, prescribing (or certifying) appropriate treatment where mental instability is established; (c) deal with feeble-minded women and girls who have borne illegitimate children, or have become infected with venereal disease.
5. Amendment of the Mental Deficiency Act, 1913, especially by extending its operation to cases of mental debility other than those existing "from birth or from an early age."

These proposals should find general acceptance as indicating the principles to be kept in view in reforming our present methods of dealing with mental weakness which leads to anti-social conduct. Such modification as they may need in detail will

be more clearly perceived when the immediate action contemplated by the Birmingham magistrates has given a more accurate and more comprehensive view than we have yet obtained of the nature and dimensions of the problem. It will then be possible to decide, for instance, whether such a psychopathic clinic as suggested in the Birmingham scheme should be primarily associated with the administration of the criminal law, or whether it might not be preferable to institute it in connexion with a general hospital, or with an out-patient department attached to an asylum for the insane. On this and on other points the decision ultimately arrived at will, no doubt, be determined very largely by the extent and character of the reforms in lunacy administration which will inevitably form part of the coming reconstruction of the health services of the nation, and which are urgently needed to bring psychiatry into closer touch with other branches of medicine. Meanwhile we may cordially congratulate Mr. BEESLY and his coadjutors on their initiation of an experiment which, in addition to its immediate practical results, should do much to stimulate the public demand for a wider application of scientific methods in dealing with the problem of criminality.

The Rôle of the Catalyst.

THE catalyst is assuming an importance no less in medicine than in industries. Chemists long ago found out the peculiar action of a third party in promoting chemical interaction. The classic example is that of the preparation of oxygen gas from chlorate of potassium. The fused mass of the salt, with heat still applied to it, yields its oxygen reluctantly, but at that point it is dangerous to introduce a trace of manganese dioxide since at once the evolution of oxygen becomes explosive though the manganese remains unchanged. An earlier example of catalysis was the Döbereiner lamp, in which spongy platinum was the catalyst effecting the union of a mixture of hydrogen and oxygen at such a speed that ignition was the result. The most remarkable catalyst of all is water, without which, it has been shown, combustion or oxidation is impossible. Similarly the louse is a catalyst in respect of man and trench fever. Catalysts, briefly, are promoters of chemical action for reasons not yet fully explained. They may function equally in the relatively cold or under conditions of high temperature. The remarkable behaviour of catalysts in the human body at its normal temperature illustrates the importance of their action in promoting healthy nutrition, which after all means the complete chemical assimilation of food substances.

We have much yet to learn as to the nature of the action of the accessory factors in food—for convenience called *vitamines*—which serve as anti-neuritic and antiscorbutic agents. It is conceivable that in the chemical sense they act as catalysts—that is, as a third party, rendering the potentialities of food available for the maintenance and growth of the organism. It is known, at all events, that they occur in quite minute proportions, in spite of which they prove to be essential to growth. When we consider the very remarkable results produced in great industrial processes by the agency of the merest trace of a third party, the catalyst, our views are strengthened as to the importance of a certain factor present in however minute quantity. There is good reason for suggesting that

the *vitamines* are catalysts just as are the enzymes, whose action in many respects resembles that of inorganic catalysts, particularly in the colloidal state. Dr. G. G. HENDERSON, in a recent valuable treatise on *Catalysis in Industrial Chemistry*,¹ says that the term "catalysis" is now generally used to designate those chemical changes of which the progress is modified by the presence of a foreign substance, and he further points out that it has for long been known that the velocity of many chemical reactions which take place very slowly if the reacting substances alone are present in the system is greatly increased by the addition of certain substances, which have the same composition after the change has been completed as at the beginning, and which therefore appear to influence the course of the reaction without taking any definite stoicheiometric part. This definition would appear to include all accessory food factors as catalysts, having no direct nutritive value themselves, but serving as promoters of a nutrient consummation.

The application of catalysts in industrial operations is growing very rapidly in importance, and the behaviour in many respects of the catalysts employed shows a curious parallel to well-known physiological phenomena. Traces of arsenic, mercury, sulphur, hydrocyanic acid, "poison" in so many cases the catalysts' activities, and there are also negative catalysts which inhibit the action of positive catalysts not by "poisoning" them but by neutralising their potentialities as acid does an alkali. Sir EDWARD THORPE, writing in his introduction to the excellent "Monographs on Industrial Chemistry" now being issued, says an obscure phenomenon like catalysis is found to be capable of widespread application in manufacturing operations of the most diverse character. The phenomenon may be obscure, but its applications are suggesting great possibilities in arts and industries which are bound to have an important bearing on the commercial prosperity of this country. The catalyst, in short, promises to open a way to important economic productions, as witness the hardening of liquid fats for food purposes, the production of fertilisers from the air, and the output of many valuable commercial products. The advances made and the vista opened up by the study of catalytic action, though confined largely to industrial processes, should persuade biologists, as well as biological chemists—we see no dividing line between these two schools of workers—to accept a cue which, followed, may lead to results in the study of life processes of immeasurable importance. The part played by conceivably a catalyst in human nutrition may, when thoroughly investigated, enable us to adopt a regimen which will secure for certain patients a dietary in which the supply of accessory factors is well represented. It is a matter of history that industrial developments have been shown to give a helping hand to medicine—the coal-gas industry with its output of antiseptics, synthetics, and colours, the brewing and wine industries which formed the basis of PASTEUR'S successful researches are cases in point. The prominent place which the catalyst is rapidly taking in industrial advances will shed a light on the chemistry of the human mechanism, its liabilities, and the factors which count in its healthy maintenance.

¹ *Catalysis in Industrial Chemistry*, by G. G. Henderson, M.A., D.Sc., LL.D., F.R.S. Longmans, Green, and Co., London, 1919, pp. 202, price 3s.

The Outlook of the Medical Practitioner.

WE publish this week a personal retrospect by Dr. JAMES PEARSE of his experiences, extending over some 20 years, of general practice, and from his sternly modest remarks there can be gathered not so much what the past has been as what the future should be. Dr. PEARSE reviews the advantages and disabilities, the privileges and drawbacks, of general practice as it existed for the mass of general practitioners before the war, and also before the passage of the National Insurance Acts brought in a system of panel practice. He would be the first to allow that there is not much in his résumé either of the difficulties of general practice or of its compensations that has not been said before, either explicitly or by inference, but we publish the essay with pleasure because it is a practical account of things as they have happened, containing at the same time large suggestions for their improvement. It not only indicates what ought to be altered, but lays stress upon what ought to be preserved. It is really a story of progress, for undoubtedly the medical student of to-day starts with a far finer equipment than the medical student of 30 years ago. Not only is his general standard of knowledge much higher, but the science upon which that knowledge is founded is more thorough, and the general principles of biology, chemistry, and physics replace in his education the rule-of-thumb tenets of the older medical schools.

But by as much as the man who now enters medical practice does so with a wider outlook than the commencing practitioner of 30 years ago, by so much does he feel the need for a continuance of his studies and of the introduction of scientific method into his professional life. It is true that the young medical practitioner of to-day, as of 20 or 30 years ago, must gain his knowledge largely from his own experience and from the exercise of his own judgment; he feels strongly, however, that he should not be called upon to alleviate the ills of the public in accordance with a set of dogmatic precepts, for he is really playing his part in a great preventive and curative scheme founded on scientific principles. And therefore he realises that he ought to be in close touch with his colleagues similarly engaged. He is aware that he should have proper opportunity to revise his knowledge by mutual counsel and to secure for his patients special consultative advice in directions where his scientific information indicates the particular treatment needed. Regarded in this way Dr. PEARSE's retrospect is a forcible argument for much of that decentralisation of medical skill and knowledge which most of the schemes for a Ministry of Health postulate. When there is a central controlling authority of medicine, and when it is perceived that all medicine should be preventive in its inclusive object, the wastefulness and cruelty of leaving the general practitioner in his present isolated position will be apparent. The original foundation of panel practice contemplated the formation of local centres of scientific medicine, to serve as rallying points for general practitioners, constituting a liaison between routine medical practice and special or laboratory development. More ambitious schemes have been published expanding this idea, and, read as a message for the future rather than a record of the past, Dr. PEARSE's essay is a demand for movement along the same lines.

Annotations.

"No quid nimis."

THE VACCINES AND SERUMS SUPPLIED TO THE ROYAL NAVY.

PREVIOUS to 1916 the greater part of the vaccines required were received from the inoculation department of St. Mary's Hospital, through the courtesy of Sir Almroth Wright. Surgeon Captain P. W. Bassett-Smith, C.B., C.M.G., R.N., informs us that since then the undernoted quantities have been prepared in the laboratories of the Royal Naval Medical School, Greenwich, by the naval staff, assisted by a civil bacteriologist, who joined for the war from Armstrong College, Newcastle:—

Typhoid vaccine, 5400 c.cm.
 Paratyphoid vaccine, 21,500 c.cm.
 Triple typhoid vaccine (Naval formula), 247,700 c.cm. The triple vaccine is a mixture of *B. typhosus*, *paratyphosus A*, and *paratyphosus B* heated to 55° C. for half an hour; 0.5 per cent. phenol is then added.
 Cholera vaccine, 8600 c.cm. (Prepared from several strains of Balkan origin.)
 Antisepsis vaccine, 48,400 c.cm. (A mixed polyvalent vaccine containing streptococci and staphylococci.)
 Influenza vaccine, 144,000 c.cm. (A mixed polyvalent vaccine containing *B. influenza*, streptococci, and pneumococci.)
 Melitensis vaccine, 1380 c.cm.
 Staphylococcal vaccine, 910 c.cm.
 All antitoxins and serum prepared elsewhere were issued to the various divisions, depôts, and ships from the school.
 Tetanus antitoxin, 14,800 doses.
 Diphtheria antitoxin, 2400 doses.
 Antidysentery serum, 2800 doses.
 Antistreptococcal serum, 1250 doses.
 Antimeningococcal serum, 5000 doses (and other sera and vaccines in smaller quantities).

During 1917 and 1918, 30,900 c.cm. of triple typhoid vaccine was prepared at the R.N. Hospital, Malta, and distributed locally to the Fleet in the Mediterranean.

Surgeon Captain Bassett-Smith has further supplied us with the following significant and valuable information in respect of antityphoid vaccines used in the Royal Navy and the incidence of cases:—

1914-1915. (Simple Typhoid Vaccine.)

| No. of men. | Inoculated once. | Inoculated twice. |
|-------------|------------------|-------------------|
| 23,448 | 1869 | 21,579 |

The differentiation of cases was not sufficiently accurate for summary, but out of the 372 reported there were among the inoculated 3 deaths and among the uninoculated 22 deaths.

1915-1916. (Simple Typhoid and Triple Typhoid Vaccine.)

| No. of men. | Inoculated once. | Inoculated twice. |
|-------------|------------------|-------------------|
| 20,663 | 1967 | 18,696 |

(12,000 were simple typhoid vaccine only.)

Total cases of enterics, 295:

| | Typh. id. | Paratyphoid A. | Paratyphoid B. |
|----------------------|-----------|----------------|----------------|
| Not inoculated ... | 24 % | 10.2 % | 11.0 % |
| Inoculated once ... | 14 % | 7.8 % | 7.8 % |
| Inoculated twice ... | 10 % | 7.4 % | 11.0 % |

(For percentage of these types see Haslar statistics.)

1916-1917. (Triple Typhoid Vaccine.)

| No. of men. | Inoculated once. | Inoculated twice. |
|-------------|------------------|-------------------|
| 21,695 | 1578 | 20,117 |

Total cases of enterics, 144, comprising 93 typhoid, 21 para. A, 30 para. B:

| | Typhoid. | Paratyphoid A. | Paratyphoid B. |
|----------------------|----------|----------------|----------------|
| Inoculated once ... | 6 | 3 | 1 |
| Inoculated twice ... | 13 | 9 | 12 |
| Not inoculated ... | 74 | 9 | 17 |

Deaths.

| | | | |
|--------------------|---|---|---|
| Not inoculated ... | 3 | 1 | 0 |
|--------------------|---|---|---|

No deaths among those inoculated.

Of the 13 typhoid cases inoculated twice, in 11 over 12 months had elapsed.

Of the 9 para. A inoculated twice, 3 had received simple

typhoid vaccine only, and in 3 over 12 months had passed since inoculation.

Of the 12 para. B inoculated twice, 2 were inoculated with the simple vaccine only.

1917-1918 (*Triple Typhoid Vaccines.*)

| No. of men. | Inoculated once. | Inoculated twice. |
|-------------|------------------|-------------------|
| 20,910 | 1486 | 19,424 |

Total cases of enterics, 96, comprising 79 typhoid, 6 para. A, and 11 para. B:

| | Typhoid. | Paratyphoid A. | Paratyphoid B. |
|---------------------|----------|----------------|----------------|
| Inoculated once ... | 6 | — | 2 |
| Inoculated twice... | 12 | 2 | 2 |
| Not inoculated ... | 61 | 4 | 7 |
| <i>Deaths.</i> | | | |
| Inoculated twice... | 1 | — | — |
| Not inoculated ... | 5 | 1 | — |

Of the 12 typhoid cases who had been inoculated twice, in 9 of them over two years had elapsed since being last inoculated, but in one the period was only 10 months, and this case was fatal. Of the two para. A, one had been inoculated six months before and one a little over a year, showing comparatively slight protection from this form of the disease. Of the two para. B, in both the cases the inoculations had been given over two years previously. The results show that the protection for typhoid and para. B is good, but at least two inoculations are required, and that reinoculations should be made not later than 18 months.

THE SPECIAL CLINICAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

THE customary annual meeting of the British Medical Association has not been held during the last four years. That meeting was formerly arranged with domestic and general subdivisions; the domestic consisting of the meetings of the Council and of the Representatives, and dealing with the internal work of the Association, the general consisting of the sections prepared to discuss the clinical and scientific work of the year. During the war the sectional debates on the various branches of professional learning have not been held, as so many prominent exponents of medicine were engaged on the medical work of the Navy, Army, or Air Force, when the annual meeting resolved itself into meetings of the Council and of Representatives. At the annual general meeting at Aberdeen just prior to the war it was arranged that an annual general meeting, presumably of the usual type and scope, should take place in the following summer in Cambridge under the presidency of Sir Clifford Allbutt, but as that date approached it became clear that no adequate meeting could be held. The University had become practically a large training camp for staff officers as well as cadets, and was so denuded of all accommodation that the hospitality of its walls could no longer be proffered. Moreover, by this time all men began to see that the end of the war was far away. The question of the next annual general meeting of the Association has been held under consideration ever since, only the domestic gatherings being held. And, now that hostilities are suspended, the position of strain in the medical profession has been so little relieved that it has been thought wise to attempt no regular annual general meeting until 1920, in which year, however, Sir Clifford Allbutt has announced that the University is looking forward to entertaining the Association. In the circumstances it has been decided that a special meeting should be held this year for the discussion of clinical and scientific subjects, but on a smaller scale as to sections than has marked

previous annual meetings. This special general meeting will take place early in April, and last for two, or perhaps three, days. A general committee has been appointed for its promotion, together with two sub-committees, one taking over the organisation and the other dealing in detail with the programme of scientific work. The decision is an expression on the part of the Association that the time has come to relay old tracks and to make plans for reconstruction, even though no attempts at a comprehensive scheme can yet be entered upon. The meeting will be held in London and its main object will be to bring together British workers and visitors from the Dominions and the United States. There will be no large disengagement from their duties before April either of our Colonial or our American colleagues, so that an exceptionally strong medical voice ought to be obtained on many subjects from a series of officers who have studied war medicine and war surgery on many spots and from many points of view. Colonel A. M. Whaley, speaking as United States liaison medical officer with the War Office, has given a warm welcome to the proposal, which has also received the support of Colonel J. G. Adami, Professor of Pathology at the McGill University, Montreal, and Colonel R. D. Rudolf, speaking for Canada, and of Colonel C. T. M. De Crespigny and Colonel Bernard Myers, speaking respectively for the Australian and New Zealand Army Medical Services. Hearty acceptance of the proposal has also been received from Sir William Norman, Medical Director-General of the Navy, Sir John Goodwin, Director-General of the Army Medical Service, and Colonel T. D. Barry, representing the medical administration of the Royal Air Force. If the scheme of the meeting is well drawn up, and precautions are taken only to admit authoritative communications, the net result for good ought to be very great. But those who draft the programme of scientific work will have to be tactful and firm, for the time at the disposal of the meeting will not allow for much duplication of opinion, or any desultory discussion of the admitted and the obvious. First-hand and new experiences will have to be given all possible opportunity for expression.

PUBLIC HEALTH WORK IN EGYPT.

WE were permitted to publish in THE LANCET some weeks ago the substance of the report of a Commission appointed in the summer of 1917 by the High Commissioner to advise as regards the future organisation and work of the Egyptian Department of Public Health. The Commission was composed of Lieutenant-Colonel Andrew Balfour, Lieutenant-Colonel G. E. F. Stammers, Mr. E. S. Crispin, director of the Medical Department for the Sudan Government, and Dr. Charles Todd, director of the laboratories in the Department of Public Health, Mr. H. Sheridan acting as secretary. It was referred to the Commission to consider the present organisation and duties of the Public Health Department and its relations with other Government Departments, and to make proposals for increasing the efficiency of the Public Health Department. In these circumstances the Commission was authorised to call for all necessary evidence, and was given access to pertinent documents and records.¹ The report is now published by the Cairo Government Press, and we trust that its highly valuable and practical recommendations will shortly be acted upon.

¹ See THE LANCET, Nov. 23rd, 1918, p. 715.

THE STORY OF LETHARGIC ENCEPHALITIS.

THE report on Encephalitis Lethargica, issued under the title of an Enquiry into an Obscure Disease, by the Local Government Board (New Series, No. 121), may justly be claimed as a brilliant vindication of the application of team-work in the elucidation of a medical problem. Attention was drawn to the appearance of the new syndrome by Dr. Wilfred Harris in the columns of THE LANCET on April 20th, 1918. The similarity between some of the symptoms and those which characterise infection caused by food contaminated with the *Bacillus botulinus* created a general anxiety which was natural in the circumstances of the time. A preliminary inquiry was started at once to determine whether food contamination could be held responsible for the outbreak. The result of this inquiry was entirely negative; no direct or indirect evidence of an association of the illness with infection from food was obtained. On the other hand, certain features, particularly the pathological examinations, raised the suspicion that the outbreak might be one of epidemic anterior poliomyelitis, or Heine-Medin disease. With a view to determining the correctness or otherwise of this suggestion the present inquiry was instituted on a comprehensive scale. The results of the well-coordinated investigation—clinical, epidemiological, pathological, and bacteriological—are contained in this report, and the conclusion arrived at is briefly that the disease is identical with that described by Von Economo in Austria and Professor Netter in France, that it is *sui generis* and distinct, both anatomically and clinically, from analogous affections—e.g., acute poliomyelitis. It belongs to the class of polio-encephalitic diseases which are inflammatory in nature, but the inquiry has not yielded any conclusive evidence as to the character of the causal agent. When it is considered that the organism which causes the analogous disease poliomyelitis is still a matter for debate, although thousands of cases have been investigated from the bacteriological point of view, it is not surprising that the problem of the causal agent of encephalitis lethargica is as yet unsolved. Sir Arthur Newsholme in his introductory review says:—

"Although a negative finding is unsatisfactory, and affords little basis for preventative action, the speedy cessation of the outbreak makes it necessary, for the present, to leave the problem at this point. Possibly a larger number of cases hereafter may supply material for further epidemiological and bacteriological research and animal experiment."

Dr. A. S. McNalty, who carried out the clinical part of the work, makes the arresting suggestion that the relation between acute poliomyelitis and lethargic encephalitis may be comparable to that between typhoid and paratyphoid. He also lays stress on the influence which diminution of resistance in individuals may have on the "evolution" of a disease. The virus may well have been fairly generally present in the human organism and the strain of the years of war may have so altered the resisting powers of certain individuals that an ordinarily saprophytic organism had become pathogenic for them. Such a suggestion is made more probable when the widespread sporadic distribution of the cases in the recent epidemic is considered, and this point is very clearly brought out by Colonel S. P. James in his epidemiological survey of the outbreak.¹ Patho-

logical investigations were carried out by Professor Marinesco, whose services were most fortunately secured through the Medical Research Committee, and by Dr. James McIntosh. Both emphasise the similarity between the lesions found and those of poliomyelitis—namely, cellular infiltration around the smaller veins in the basal ganglia, the upper part of the pons, particularly in the grey matter of the floor of the fourth ventricle, and to a much less degree in the medulla. Both failed to find satisfactory evidence of the presence of a specific micro-organism, and the intracerebral inoculation of monkeys with emulsion of diseased tissues carried out by Dr. McIntosh was void of result. The only striking pathological difference was one of localisation. Yet here combined work supplied the corrective. The masterly analysis of the clinical differences set forth by Dr. McNalty, supported as it is by the epidemiological evidence, leaves no reasonable doubt that the two diseases are separate entities. Sir Arthur Newsholme and his coadjutors are to be congratulated upon this report as an instance of what can be achieved by orderly scientific investigation.

NATIONAL REGISTER OF POPULATION.

AT a meeting on Jan. 6th of the Commission for the Reconstruction of the National Birth-rate an urgent appeal was made on behalf of the Registrar-General by Dr. T. H. C. Stevenson for the establishment of a national register of population, which should supersede the many partial registers in present use. The list already includes, in addition to the national and electoral registers, the school attendance and food registers, and those relating to sickness, unemployment, insurance, and some others. Sir Bernard Mallet, in full accord with his predecessors, lay as well as medical, at the General Register Office, once again revives the official demand for a complete registration system on the ground that the Census, which is the only complete register, is revised not more frequently than once in ten years. It therefore rapidly becomes out of date, and is of little value except for statistical purposes. Practically all the registers now in vogue are independently compiled and maintained, the information contained in each one being seldom available for the purposes of the others. The Registrar-General accordingly proposes that a single master register should be inaugurated which should include every man, woman, and child in the country, giving particulars of name, address, sex, age, occupation, and date of birth, together with information as to marriage and family. But inasmuch as no single register could possibly contain all needful information, it is proposed to link up each unit with the general register as part of a co-ordinated system, providing for the communication to each of the special registers of the information of common interest collected by the general register, and leaving each of them to amplify this according to individual requirements. For this purpose the general register might record, in code form, the necessary particulars, and information respecting removals could be communicated to the local branches as required. As this register would deal with many millions of names it would have to be arranged in local sections throughout the country. Nevertheless, it would be necessary to maintain at headquarters an index to the local registers everywhere. To this

¹ THE LANCET, 1918, II., 837.

central index all births, deaths, and removals would of course be referred, but it is essential that all local registers should be controlled and coördinated by the central organisation.

With the object of allaying the fears already expressed that the present proposal would result in the exaction of family secrets to which objection might be taken, Dr. Stevenson was able to assure his hearers that the new proposals did not increase in any way the statutory information hitherto demanded from the public. It only altered the form in which it would be required. The Commission resolved—

"That in the view of the National Birth-rate Commission there is immediate need for the improvement of the vital statistics upon which all its conclusions must be based by the formation of a joint register on the lines advocated by the Registrar-General."

The meeting was presided over by the Bishop of Birmingham on behalf of the National Council of Public Morals. The apparently imminent establishment of a Ministry of Health, and the appointment of Dr. Addison and Sir Auckland Geddes as heads of the departments concerned, would indicate the present moment as judiciously chosen for the presentation of the Registrar-General's request. This seems to us reasonable and necessary for the discharge of the additional responsibilities which the establishment of a Health Ministry would entail on his department, and for the fulfilment of which a complete system of registration would be indispensable.

THE EUROPEAN FOOD SITUATION.

WE have received from the Provisional Committee on the European Food Situation (77, Avenue Chambers, London, W.C. 1) a letter signed by Lord Parmoor intended to bring the facts of the European famine, due to the continuance of the food blockage, before the medical profession and to obtain their opinion upon its probable results. The facts are substantiated as regards Vienna by a translation of an article published on Dec. 27th in the *Arbeiter Zeitung* by the vice-burgomaster of the city, and of the statistical material laid before the Inter-Allied Commission by the burgomaster of Vienna. The percentage of deaths attributed with certainty to malnutrition is given as 7 per cent. or over for each month since last July, and there is a presumption that the actual proportion is more than double that figure.

DURING the fourth quarter of 1918 98,998 deaths from influenza were registered in England and Wales; this number, though given officially, is provisional.

At a general meeting of Fellows of the Royal Society of Medicine, held on Jan. 14th, the conditions were discussed under which pensioners should be admissible to treatment in civil hospitals. We have been obliged to hold over a detailed report of this important discussion until our next issue.—The Council of the Society has decided to have a social-scientific evening once a week for the reception of officers attached to the R.A.M.C. and Red Cross, and officers of the Medical Services of the Dominions, the United States, and other Allied Powers. The reception will be held every Wednesday evening at 8.30, when a short informal discourse will be given, after which it will be free to any present to raise and discuss any question in which they are interested. The first discourse will be

given on Wednesday, Feb. 5th, at 8.30 P.M., when Sir John Bland-Sutton will discourse on Gizzards and Counterfeit Gizzards, illustrated by specimens.

Sir Arthur Newsholme's impending retirement from the medical officership of the Local Government Board is announced. The good wishes of the Public Health Service, which he has served so well, go with him.

A COURSE of four lectures on Malaria will be delivered at noon on Jan. 31st, and Feb. 7th, 14th, and 21st, in the Lecture Theatre of the Medical School, King's College Hospital, by Colonel Sir Ronald Ross. Officers and men of the R.A.M.C. are invited to attend. Microscope specimens and lantern slides will be shown at the two last lectures.

THE Council of the National Medical Union decided in December last to invite a mass meeting of the medical profession to consider the establishment of a medical advisory body in connexion with the proposed Ministry of Health. This meeting, which will be open to panel as well as to non-panel practitioners, will be held at the Wigmore Hall, London, W., on Sunday, Feb. 2nd, at 4 P.M.

A special meeting of the Faculty of Insurance will be held on Tuesday next, Jan. 28th, at 7 P.M., at the Central Hall, Westminster, when an address will be delivered by Mr. E. B. Turner (chairman of the Medical Committee for Combating with Venereal Disease) on Venereal Disease considered as an Urgent Health Problem. Mr. P. Rockliff (President of the Faculty) will initiate a discussion on Prophylactic Treatment.

AT the meeting of the Medical Society of London to be held on Monday next, Jan. 27th, at 8.30 P.M., a discussion will take place on "The Modern Treatment of Gonorrhoea of the Genito-Urinary Organs." The debate will be introduced by Colonel L. W. Harrison, R.A.M.C., who will be followed by Dr. D. Thomson, Dr. R. A. Bolam, Dr. A. Campbell, Dr. D. Lees, Dr. David Watson, and Mr. Campbell Williams, among others. Medical officers of the Colonial and Allied Armies will be welcome at the meeting.

THE LANCET, AUGUST 24TH, 1918.

THE Manager of THE LANCET would like to re-purchase or to receive copies of the issue of August 24th for which readers may have no further use, to enable him to replace copies for libraries and institutions in India and the East which were lost at sea owing to enemy action. Such copies should please be addressed to him at 423, Strand, London, W.C.2.

THE LANCET, VOL. II., 1918: THE INDEX.

THE Index and Title-page to the volume of THE LANCET which was completed with the issue of Dec. 28th, 1918, is now ready, and copies have been supplied gratis to those subscribers who have, up to Jan. 22nd, intimated to us their wish to receive them. Other subscribers will be similarly supplied, so long as the stock remains unexhausted, on application to the Manager, THE LANCET Office, 423, Strand, London, W.C. 2. Such applications should be sent in at once.

PROSTHESIS OF THE LOWER LIMB.

BEFORE the war amputations of the limb were becoming rare; now the number of British sailors and soldiers requiring an artificial leg is about 40,000, a number sufficiently large to give rise almost automatically to inquiries as to the construction of artificial limbs. Although the problems presented by artificial limbs have not been completely solved in the case of the lower limb, a considerable measure of agreement as to the modes of their solution exists; for this reason the following article is limited to the consideration of this part of the subject.

Condition of the Stump.

Before an artificial limb can be fitted the stump must be in a suitable condition for wearing a limb. Owing to the unfavourable conditions under which many of the primary amputations have been performed subsequent trimming operations (or rarely re-amputations) are necessary in the majority of cases. At the beginning of the war 90 to 95 per cent. of amputation stumps seen at a German limb-fitting hospital required a second operation to render the stump painless and capable of wearing a prosthesis, but this proportion during the second year of the war diminished to 75 per cent.

The stump must be covered with sound movable soft parts which, however, must not be excessive in amount, especially if any part of the weight of the body is to be borne on the end of the stump. Excessive mobility of the soft parts of a stump is detrimental. The mobility is brought about by the surgeon, instead of fixing the muscular aponeuroses to the end of the bone, suturing the flexor and extensor masses to each other across the end of the bone and healing taking place without adhesion between the aponeuroses and the bone. When the patient attempts to move the stump the first effect is the movement of the scar to and fro over the end of the bone. When a limb is fitted and the patient tries to walk much power is lost by this movement; friction between the skin and the limb is liable to produce abrasions.

The scar should be thin, movable, and neither eczematous nor ulcerated. Ulceration of the scar often results when a guillotine amputation (usually performed as a temporary measure) is not followed by a re-amputation; the fibrous scar resulting often gives rise to trouble. On flexion of the artificial limb the soft parts of the stump are dragged up, thus interfering with the nutrition of the scar.

When the skin flaps are voluminous a troublesome eczema of the skin is sometimes seen. The skin is usually adherent to the bone; the condition is usually the result of a secondary operation performed while the tissues were in too septic a condition to allow of primary union.

Scars over the end of the bone do not always prevent the use of an end-bearing pad.

A posterior scar is to be preferred in all amputations of the thigh and leg where considerable pressure has to be borne by the front of the lower end of the stump when the artificial limb is lifted or swung forward.

Although the best end-bearing stumps are those in which the section has been made through cancellous bone, end-bearing is possible when the section has been made through the compact bone and medullary cavity of the shaft. In the lower part of the leg the area of bone is too small to permit of end-bearing; in view of the fact that a stump of 7 to 9 inches in length affords sufficient leverage re-amputations are often permissible in this region.

Outgrowths of new bone-forming spurs rarely give rise to trouble; they are seldom large except in the thigh, when they are usually found at the inner side of the end of the bone, a situation not exposed to much pressure.

Other conditions obviously requiring treatment before the fitting of a limb include painful nerves and the presence of sinuses. If necessary surgical measures must be taken to render the movement of the joint above the site of amputation as free as possible; daily passive extension of the hip-joint as soon as the condition of the wound allows does much to prevent a deformity commonly found.

Provisional Appliances.

Universal opinion in Germany, Austria, France, and Belgium is in favour of the use of a provisional limb as early as possible; the use of crutches is not allowed any more

than is inevitable. The disadvantages of crutches include the danger of crutch palsy, the alterations of balance caused by the long use of only one leg, and the loss of power in the muscles of the stump. Besides preventing these disadvantages the use of a provisional limb also prevents pain and stiffness of joints; the circulation in the stump is improved, healing and shrinking are expedited, and end-bearing promoted.

In the case of the lower limb the provisional appliances often takes the form of a Thomas's knee splint attached to the body by a suspender passing over the shoulder on the sound side. Flexion of the hip is assisted by the use of a strap attached in front to each side of the splint. The stump is encased in a plaster socket in which the sides of the splint are incorporated. Professor Mommson uses a plaster socket and fastens to it the finished artificial limb.

Provisional appliances can be used five or six weeks after the amputation.

Construction of the Bucket: Materials Used.

The first point to consider in regard to the artificial lower limb is the construction of the bucket. No definite conclusion has yet been reached as to which is the best material. Although at present in practically every instance the bucket is made of wood or of leather, strengthened with steel supports, both these materials have disadvantages which prevent their being ideal. Leather has a tendency to "give"; the shrinking of stumps after fitting prevents a cavity carved out of the interior of a wooden block to fit a stump in its earlier condition from being satisfactory at a later stage.

Experiments are being made as to the suitability of other materials. The value of such different materials as ply wood and glue, combined with muslin bandages, is being tested. A specially prepared liquid glue is well worked into the muslin bandage while it is being wound round a plaster-of-Paris cast. When dry the surface is rubbed with sandpaper and varnished. The material, it is claimed, is equal to celluloid or acetone, but is very considerably cheaper; it is light, strong, non-flammable and, when varnished, practically impervious to moisture. At La Panne Dr. Martin is experimenting with wood shavings and glue. With a plaster model of the stump as a foundation, he glues together several layers of beechwood shavings, each layer being arranged in a different direction. The glue is especially prepared with the object of rendering it impervious to moisture.

The great advantage afforded by the use of wood is the independence of the external form of the limb of the shape of the socket; this feature is not presented by any other material used in the construction of limbs. Of the various woods used for the purpose, willow is the most popular in England and America. It combines the maximum of strength with the minimum of weight; in addition to being pliable it has the advantage of not undergoing any change of form under the influence of changes in the humidity of the atmosphere. Seasoned wood is best, but unfortunately owing to the greatly increased demand kiln-dried wood must now be largely used; this method of drying increases the liability of the wood to crack.

Methods of Fitting the Bucket.

At Roehampton House the process of making artificial limbs can be seen from start to finish. The trunks of willow are sawn into appropriate lengths for thigh and leg pieces, the bark trimmed off, and the block roughly hewn to its future shape. If intended for a thigh bucket the central portion of the block is "pulled" (drilled out) by a machine. The shapes of the top and bottom of the bucket are roughly outlined on the ends of the block and superfluous portions removed by a band saw.

Various methods are used to ascertain the dimensions of the stump. Plaster casts are still held in favour by some fitters; the stump is bandaged with plaster-of-Paris bandages and allowed to set; with this as a mould a cast is made. Certain precautions are necessary: To reproduce the form of the stump, when wearing a bucket, as accurately as possible the stump is bandaged with the patient in the erect position. To reproduce the alteration of form caused by pressure on the end and sides of the stump by the end-bearing and bucket, a sock is worn over the stump and pulled up tight before the bandage is applied. Care is taken to mould the plaster well on to those points on which pressure is borne; in the case of the thigh the fist brings pressure to bear just below the ischial

tuberosity. When the interior of the socket is being "pulled" trial is made from time to time of the progress by inserting the plaster cast.

Other fitters work "in profile"—measurements are taken, including the length of the stump and its circumference at different levels; a diagram is sometimes made by carrying a pencil along the inner and outer sides of the limb and stump when the patient is resting with his limb in the horizontal position over a piece of paper. The size and shape of the section of the stump at different levels are reproduced in a set of "charts" made of flat pieces of leather or metal, the outline of each chart being a reproduction of the form of the stump at the corresponding level; with these to help him to determine the desired shape the maker "pulls" the interior of the rough bucket.

Adaptation of Buckets for Various Amputations.

Certain amputation stumps, including those resulting from a Stephen Smith and Syme's amputation, are practically always covered with a leather socket. In these cases plaster casts are made, or limb and stump are reconstructed in wood from measurements; on these casts or lasts the leather is moulded. Workers "in profile" claim that they succeed in producing a bucket which grips the stump more closely than when the size of the socket is determined by the insertion of a plaster cast. In the case of a below-knee stump the lateral diameter of the limb is greater opposite the head of the fibula than at the higher level through the knee-joint; if made by cast the diameter of the top of the bucket must be equal to the greatest diameter of the interior, so as to permit the introduction of the cast; in these cases a gap is left between the stump and the inner surface of the socket above the level of the head of the fibula.

In the case of a thigh stump a considerable alteration in the form of the inner surface takes place when the limb is used for walking; contraction of the adductor muscles, especially the adductor longus and adductor magnus, then occurs.

In a recent amputation of the leg of a well-developed man the head of the fibula and the anterior tuberosity of the tibia are not prominent, but soon become so as the stump shrinks. If allowance is not made for these projections they give rise to troublesome bursae. The plaster mould then gives an impression of the stump in its present form; by altering the "charts" or "lasts" slightly to correspond with the size and shape that experience has shown will within a comparatively short time be assumed by the stump a better permanent fit, it is claimed, is produced.

The shape of the top of the thigh bucket is determined by the ischial tuberosity and the anterior part of the perineum. The ischial tuberosity is the only bony point on which pressure can be borne; to ensure that the tuberosity rests on its upper border the bucket is so constructed that the diameter at this point is less than the diameter of the limb.

The anterior part of the perineum is unable to bear pressure; the bucket must be cut down to clear this part.

In a limb for a thigh amputation the roughly made thigh bucket is "keyed" on to the knee-piece, to which is attached the leg-piece and foot with the boot on; the patient is fitted at least twice while the limb is in the rough state.

Other Points in Regard to the Bucket.

The tendency of all wooden buckets to crack is in the case of the American limbs prevented, or at least the cracking is localised, by the use of a thin covering of raw hide. This membranous covering is thoroughly wetted and spread evenly over the whole of the outer surface of the bucket, exposed to the action of heat, and then varnished; the result is a transparent covering, the presence of which can only with difficulty be detected.

The Hanger bucket is further strengthened by the insertion of screw wires tangentially to the inner surface at levels where experience has shown strengthening is required; in the case of the thigh these wires are inserted at a distance of 1 inch or 1½ inches from the edge of the socket.

A ventilation hole is always provided below the end of the stump; above this hole comes the end-bearing pad, usually made in the form of a net of intercrossing leather laces fastened through small holes to the side of the bucket.

The average life of an artificial lower limb is about three years. In the case of the first limb worn this depends to a considerable extent upon the rate of shrinking of the stump. Every patient wears at least one stump sock; these are of uniform thickness and obtained through the limb-

makers. If shrinking of the stump causes the socket to become too large another sock is added. The limit is usually reached when the man is wearing five or six socks; the bucket is then lined with leather, and if this does not suffice must be renewed. As a rule the stump ceases to shrink by the end of two years after amputation, but in a few rare instances shrinking may continue as long as seven years.

The Knee-joint.

Other parts of the prosthesis will now be described. In the construction of the knee-joint it is essential that the bolt should be placed behind the centre of gravity of the anatomical joint. If the axis of the artificial joint corresponds in position with the anatomical centre a slight degree of flexion of the knee brings the line of action of the body-weight behind the axis of the joint, when further flexion must occur. If the axis of the joint has been displaced posteriorly the weight of the body falls in front of the axis and tends, instead of producing further flexion, to lock the knee.

The distance the axis is set behind the centre of gravity of the joint depends upon the particular leg-maker. Perhaps the usual distance the axis is set back is between $\frac{1}{2}$ and $\frac{3}{4}$ inch; this amount, while allowing a sufficient margin of safety, does not interfere with the naturalness of the gait. If the axis is set further back the patient, when bringing from the flexed to the extended position, swings his foot in a slightly longer arc, causing the action to appear unnatural.

During weight-bearing the rigidity of the knee-joint is secured by the simple means of mounting the foot in a position of equinus. When the artificial limb is swung forward to take a step the heel comes in contact with the ground first; then, as the leg becomes vertical, the entire sole lies flat on the ground; with the foot in equinus this position is to all intents and purposes only possible when the knee is hyper-extended. When, therefore, the sole of the foot slopes obliquely downwards and forwards and the weight is taken on the toe the weight of the body acting vertically downwards tends to force the lower end of the thigh-piece into the hyper-extended leg-piece and prevent any movement of the two parts on one another.

As the thigh-piece is attached to the leg-piece by means of a spindle which passes through a metal eyelet hole projecting upwards from each side of the leg-piece, the action takes place between the spindle and the sides of the holes rather than between the surfaces of the thigh and leg pieces.

An arrangement must be provided to extend the leg-piece on the thigh at the appropriate phase of the step. The patient on raising the foot of the artificial limb to take a step raises and moves the limb forward by active flexion of the hip-joint; the weight of the leg-piece causes it to assume a vertical position, and thus bends the knee-joint. But during the weight-bearing phase the leg-piece must be in a vertical line with the thigh-piece. The change of the leg-piece into this position is effected by the action of gravity; when the patient is supporting himself on his sound limb the weight of the artificial limb causes it to swing forward like a pendulum. This movement is, however, both slow and incomplete. Some patients learn to supplement this pendulum movement by flexing the thigh slightly as soon as the foot touches the ground, but although this may suffice when the stump is long and the leverage in consequence powerful, in most cases some mechanism is required if the patient is not to walk with short steps and a mechanical gait.

Control of the knee is effected by cords pulling on the front end of a short lever which has the knee-bolt as a fulcrum, the posterior part of the lever being attached to the back of the leg-piece or the foot. Two cords are provided; these run over a roller and are hooked on to the front and back ends of a double suspender passing over both shoulders. When the patient raises his leg from the ground the weight of the appliance makes the cords tense; the pull on the front of the lever extends the leg-piece. By bracing up his shoulders as he throws his limb forward the patient can assist in the extension of the leg. The object of the roller is to do away with to-and-fro movements of the suspenders across the shoulders, substituting the movements of the cords round the roller inside the knee-piece.

The "knee control" used in the Hanger leg allows of an alteration of the rapidity with which the leg is extended. By tightening the suspender, the distance of the end of the lever from the fulcrum can be altered; a hinge-joint in the lever enables this alteration in length to be effected.

A knee-locking device must be provided for patients who by reason of shortness of the thigh stump are unable to control the movements of the knee-joint, or whose daily life entails much going downstairs or walking downhill. In its simplest form the knee-lock consists of a piece of stout wire running along a canal in the outer side of the bucket; this wire can be pushed down between the knee-piece and the inner surface of the leg-piece, which is guarded at this part by a metal plate; the thick wire serves as a wedge between the two parts and prevents movement.

An automatic knee-lock has been devised by Mr. F. H. Oritchley, of Liverpool. The joint consists of a very narrow barrel attached by side-irons to the thigh-piece; circumferentially to this is placed a cylinder of metal attached to the central tube of the leg-piece. The circumference of the barrel is gripped by a band-brake tightened by the pull of a rod attached to the heel. When the weight of the body is thrown on the toe-piece the foot rotates at the ankle-joint, depressing the heel, thus pulling on the rod and locking the knee-joint. This action takes place no matter the position of flexion of the knee when the weight of the body is placed on the artificial limb. When the pressure is no longer exerted on the foot, the knee-joint automatically becomes loose and the leg-piece free to swing. The band normally tends to open by its own resilience, but a compression spring is usually added to ensure the opening taking place. The range of movement of the knee-joint is limited by an external stop.

The Ankle joint.

A movable ankle-joint is now almost universally used, but the movements are commonly limited to those of flexion and extension. With the boot on, the part of the foot representing the articular surface of the ankle-joint is horizontal. The surface of the leg-piece forming the front of the joint is inclined at an angle of 15° with the ground, the back part at an angle of 30° . The wider posterior angle renders possible the degree of flexion of the foot required when the patient walks downhill.

The following describes an arrangement in common use. On the upper surface of the foot two cavities are hollowed, one in front of, the other behind, the bolt of the ankle-joint; in each of these cavities is placed a cylinder of rubber, the posterior about twice as high as the anterior. On these cylinders rests the leg-piece, ending in front in a short instep lying within the cavity hollowed out in the foot. The foot is attached to the leg-piece by a bolt made in the form of an inverted T; the base formed by a steel tube which fits into two corresponding grooves in the leg and foot is attached to the leg by the vertical part, a rod which is secured by a nut at the bottom of the hollow of the leg-piece. Upon the steel tube moves a steel U-shaped staple, the two ends of which pass through the foot and are fastened in position by two nuts secured by a locking-nut.

The ankle-joint must be kept tight enough to prevent any side motion, but not too tight to interfere with the movements of flexion and extension. The freedom of movement of the joint can be altered by tightening the nuts and compressing the rubbers, or *vice versa*, or by altering the size of the rubber buffers. If the locking-nut is not kept in position the foot works off and breaks.

The Foot.

The foot is now usually made of wood. To allow of its bending when the patient comes forward on the front part of the foot for the next step the foot is divided transversely at a level corresponding to the middle of the metatarsal bones. The front part is attached by a dorsal and plantar piece of leather or rubber reinforced by wire; between the two parts are two rubber cylinders which, when the limb is at rest, keep the toe-piece extended at an angle of about 15° , but allow of extension to 45° when the foot is pressed on the ground.

As mentioned above, the foot is mounted in the equinus position; the heel is 2 or 3 cm. off the ground, the usual height of the heel of a boot. The foot should point slightly outwards, as in the normal standing position, the usual angle being 18.5° .

Amputations Through Hip-Joint and Upper Thigh.

Special considerations for each amputation remain to be dealt with. For amputations through the hip-joint the "tilting table," perfected during the war, is the most satisfactory appliance. It consists of a leather socket moulded round one half of the pelvis, reaching upwards as high as the iliac crest and attached to the trunk by a pelvic band.

The pelvic band is a steel girdle which rests on the iliac alae and extends a short way in front of each anterior superior iliac spine; it is covered with leather and buckled together in the front. The metal is moulded to the patient's body while in a soft state, and is then tempered. To the socket an artificial limb is attached by steel supports.

To enable the patient to bend the limb at the level of the hip-joint when he sits down a hinge-joint with a spring lock is placed in the outer steel support; this joint automatically locks when the patient rises, enabling him to walk with a rigid leg. On the inner side the steel piece runs around on a quadrant fastened to the under surface of the leather socket.

The "tilting table" has also proved to be the most suitable appliance for high amputations of the thigh, leaving a stump of less than 7 inches in length. These stumps are often incurably flexed and abducted; also the patient with so short a stump is unable to control an artificial limb. When wearing this appliance the patient sits on his flexed stump, the end of which protrudes slightly through a hole in the front of the moulded socket.

If a patient with an amputation of the thigh has difficulty in controlling the artificial limb, a pelvic band should be fitted. A properly fitted pelvic band not only ensures firm fixation of the limb, but also prevents eversion of the foot and rotation of the bucket.

Amputations About the Knee.

A complete end-bearing is often possible in the case of amputations through the condyles of the femur, disarticulations of the knee, and very short stumps below the knee.

If a wooden bucket is to be worn, owing to the bone at the lower end of the stump being larger than at a higher level a modification of the bucket is necessary to ensure its gripping the stump firmly. The front of the lower half of the bucket is cut away and the wood replaced by leather, which laces in the middle. It is perhaps more usual of late, instead of using a wooden bucket, to encase these stumps in a tightly fitting case of sole leather.

When a trancondylar operation has been performed before the plaster mould is made it is as well to pad the edges of the cut femur. The length of the stump does not leave sufficient room for the use of a knee-bolt; movement of the knee-joint is permitted by two hinged side-steels identical with those used for below-knee amputations; these steels lock dead tight when the knee is in the position of extension.

Amputations Through the Leg.

A wooden socket can be fitted to amputations through the leg if the stump is at least 6 cm. long, if the knee-joint moves freely and can be fully extended by the patient, and if no adherent scars are present round the tuberosities of the tibia. The wooden bucket is fitted accurately to the head of the tibia and to the lower portion of the patella; it must grasp the tuberosity of the tibia firmly. The patellar tendon is capable of weight-bearing. Care must be taken lest the bucket press on the head of the fibula; a deep concavity must be present at this point.

The shape of the top of the bucket is important. To avoid nipping the flesh between the upper edge of the bucket and the lower end of the thigh corset, both these edges must be concave; a concavity of a finger's breadth below the axis of the joint suffices. The back of the socket is flattened; if hollowed out too much at this point the stump is tilted forward and the flesh at the back of the knee pinched.

The leg is usually attached to the thigh by a leather corset; side steels, hinged at the knee, connect the corset and socket.

The shorter the stump below the knee the larger the bearing surface, and therefore the better the end bearing; but on the end of any round stump, provided an adherent scar is not present, a part of the weight of the body can be borne. Occasionally, however, it is found necessary to fit a leather thigh bucket reaching up as far as the ischial tuberosity, which bears part of the weight.

The wearing of braces increases the stability of the limb and allows of looser lacing of the thigh corset, with the consequent advantage of freer movement of the thigh muscles. The braces pass over the shoulder of the sound side and are attached either to the thigh corset or the leg-piece. If the stump is short it is an advantage to attach the brace to a strap from which two branches pass down in the form of an inverted V and are fixed to the front of the leg-piece.

In the case of short stumps a leg socket should be fitted whenever possible; with the kneeling leg the gait of a patient is much less natural than when a socket is worn. When the patient has to walk on the bent knee a moulded leather bucket is provided, similar to that used for transcondylar amputations; a posterior band passing over the end of the flexed stump helps to keep the artificial limb in position.

Syme's and Chopart's Amputations.

In a Syme's amputation the end of the stump should be able to bear the weight of the body. The stump is usually fitted with a leather bucket strengthened with steels, usually four—an external, an internal, and two anterior; it rests on a cushion within the bucket. An elastic strap is attached to the top of the instep and above to each side of the front of the socket.

If the end of the stump remains sensitive the patient must wear a leg bucket, embracing the head of the tibia. In rare instances a thigh corset, with side steels jointed at the knee, must be worn.

In a true Syme's a sufficient vertical depth exists below the end of the stump for the joint to be placed at the level of the normal ankle. If the malleoli have been left the joint must be placed in the lateral steels outside the boot.

Chopart's amputations are often unsatisfactory; in about half the cases the action of the tendo Achillis and the tibialis posterior causes the foot to assume a position of equino-varus when the patient walks on the anterior end of the os calcis and astragalus. If the position of the foot is satisfactory a leather casing is moulded accurately to the foot and ankle and attached to the instep of the anterior half of the foot. Side steels are usually necessary; these should be jointed opposite the ankle-joint to permit of free flexion of this joint.

Standardisation.

Finally comes the question of standardisation. The large number of artificial limbs required has caused attention to be directed towards the possibilities in regard to this. The chief advantage to be gained from standardisation is the ease with which a damaged part can be replaced; a certain saving of money will also be effected, but only slight, because the cost of a limb is due not so much to the expense of the material as to the cost of labour. Another advantage would be the possibility of ensuring the same quality of material in each limb.

It is obvious from what has been written above that standardisation of the bucket is impossible, but standardisation of the component parts of the limb is possible in many cases.

The Army, before and in the earlier stages of the war, was composed of men of more or less similar physique; certain standards as regards height and chest measurement were maintained, with the result that the physique of the average soldier ranged within circumscribed limits. Even later in the war when these standards were more or less abandoned, by a process of more or less conscious selection, the men in the fighting line were in most cases similar in physique to those of the earlier Armies.

On analysis of the measurements of men with amputations it was found that, excluding about 15 per cent. for the purpose of fitting artificial limbs, the sizes of the various parts required could be grouped into four—four sizes of feet, four sizes of leg-pieces, and four sizes of knee-pieces. With these three parts 64 combinations can of course be made.

The four sizes of feet correspond with Nos. 7, 8, 9, 10 sizes in boots. The leg-pieces are of such a form as to be suitable for the tall thin man, the man of average height and proportions, the short stout man, and the bantam—i.e., the small, well-proportioned man. It is the exception for a tall man to possess a big calf. A fat man over 6 feet in height probably suffers from some physical disability which would prevent his being accepted as a soldier; the tall very muscular man with a well-developed calf would be included in the 15 per cent. of exceptions. The four sizes of knee-joint correspond with the different sizes of leg-pieces and feet.

One size and form of ankle-joint suffice for all sizes of the other parts. The knee-bolt, with side plates fastening on to the leg-pieces, are made in four sizes, corresponding with the different sizes of knee-piece.

Another part which it is possible to standardise is used for below-knee amputations: this is the side steels for which one size only suffices.

THE INTER-ALLIED FELLOWSHIP OF MEDICINE.

A WELCOME TO THE HARVARD MEDICAL UNIT.

THE Executive Committee of the Inter-Allied Fellowship of Medicine gave a dinner at the Connaught Rooms, Great Queen-street, on Jan. 15th to the members of the Harvard Medical Unit at present paying a short visit to London, and on their way home from France, having served with the British Army since the second year of the war. Sir WILLIAM OSLER, the chairman of the Executive Committee, presided over a distinguished gathering of medical men who acted as hosts to the Harvard Unit. A letter of regret having been read from the American Ambassador for his inability to be present, the toast of "Health and Prosperity to the Harvard Unit" was given by Dr. NORMAN MOORE, President of the Royal College of Physicians of London.

Dr. NORMAN MOORE said:—

This afternoon I was examining a portrait of the first Fellow of the Royal College of Physicians, Dr. John Chamber. He was elected a Fellow of Merton College, Oxford, in the year in which America was discovered. The portrait was a most beautiful copy by Isaac Oliver of a work of Holbein, and as I examined its wonderful execution I was interrupted by a message asking me to propose the health of the Harvard Unit at this dinner, so I had at once to turn my thoughts to America, which I had never visited, and to Harvard, the fame of which we all know. I remembered that in the ancient church of St. Bartholomew, which stands over the way near the hospital with which I have been connected all my professional life, there is the richly adorned tomb of Sir Walter Mildmay, Chancellor of the Exchequer to Queen Elizabeth. He was a Puritan, and there are no figures upon his tomb, not even his own effigy, and, in addition to his epitaph, only the very serious inscription, "Mors nobis lucrum." He was the founder of Emmanuel College, Cambridge, where Harvard was educated. It is a college not unconnected with medicine; indeed it comes into the history of Sydenham, one of the most illustrious of English physicians since he wrote one of his medical epistles to Dr. Henry Paman, who became a member of Emmanuel in 1643, and was a life-long friend of his. As I looked into my memory I regretted more and more that I had never been to America. What can that famous land be like? Our old writers said El Dorado was there. In our day, when the place of some famous picture is vacant on a wall and we ask where it is, the answer is, that it has gone to America. When a library of rare books has empty shelves and the visitor asks where the books are, the answer is the same—America! Wonderful land, well knowing how to put their riches of El Dorado to good purpose. I am glad that its inhabitants should enjoy pictures and books which are worth seeking in our old world, and that they are worthy to enjoy them. But your country has a finer product than gold, a greater store at home, a nobler export to improve other nations. It produces the greatest of all the products of the world—men. The Harvard Unit is a collection of observant, ingenious, laborious, and thoughtful men, who brought their energies to help England's need, and I offer them affectionate salutation, regard, and gratitude.

Lieutenant-Colonel HUGH CABOT, C.M.G., R.A.M.C., Commanding (Harvard Unit) 22 General Hospital, responding to the toast, said:—

Now that the "Harvard Unit" has ended its mission and, like the many things referred to by Dr. Moore a few moments ago, is about "to go to America," it is perhaps possible to estimate in some degree what has been its effect and what it has really accomplished. It was the outcome of a great spirit of restlessness which existed all over the United States as the attempt to "keep the country out of war." It is perhaps not unnatural that this spirit should have been particularly evident at Harvard and that she should have desired to assist the country from which she sprung in the defence of democracy. Many of the plans with which we started, and particularly our surgical equipment, had to be revised as not suited to the existing conditions, of which we were naturally ignorant. Only the other day in winding up the affairs of No. 22 General Hospital, B.S.F., which this Unit has carried on since July, 1915, I found that we had in hand a very large number of surgical instruments which had not been out of their original cases, and which, though not well suited to the surgery of war, will, I believe, be found well adapted to the usages of peace. They have been presented to St. Bartholomew's Hospital as a token of our appreciation of many kindnesses and much assistance given by Major-General Sir Anthony Bowlby.

The original conception of the Unit was that it should provide the staff of a British base hospital for a period of three months and that it should then be succeeded either by Columbia or Johns Hopkins. This plan, however, fell through, and it devolved upon Harvard to continue the work alone if it was to be done at all. It was not, however, until December, 1916, that the importance of service for the duration of the war was realised, and at that time the Corporation of the University voted to continue the Unit for duration, and the officers were given commissions in the R.A.M.C. Then, for the first time, it was possible to make plans for the future, and develop the Unit into an efficient and hard-biting organisation. We cannot, I think, claim to have contributed much that is new or strange to the surgery of war, and perhaps if we had done so we might have laid ourselves open to the charge of being aggressively American. We have, however, tried to turn out a large amount of satisfactory work, and no matter how great the pressure for help might be we have always been able to find some. We have, to some extent, acted as a clearing house for American ideas, and have done something to extend the use of direct blood transfusion in the treatment of hemorrhage and shock.

Looking back now I believe that our most important work has been in bringing together the profession on both sides of the Atlantic.

We have sent many officers to work with clearing stations in forward areas, and in this way have brought them in contact with the British brethren. It is only since I have been intimately associated with Englishmen, Scotchmen, Irishmen, Canadians, and Australians that I have come to realise that we were, in fact, the same blood—that the differences were wholly superficial, though at times very apparent. These differences are largely matters of manners and mode of expression. The American, for instance, almost always overstates his case, and his use of superlatives is exceedingly common. The Englishman, on the other hand, generally understates his, and often appears to be trying to conceal the fact that he has a case at all. His very modesty may make him appear to his American brother as a dull fellow without much to say for himself. The American always puts his best foot foremost and selects with care that which is best polished, whereas the Englishman is likely to put forward the one that is least presentable for fear someone might think that he was trying to attract attention. Though these habits and manners nowhere touch the essentials of the men they make a brave show, and to the superficial appear to be important, and do, in fact, delay progress in the close association which we must have in the future. On the other hand, I have been deeply impressed by the fact that in a close working association Englishmen and Americans soon come together, and each sees and admires the qualities of the other. Therefore, I say to you that we must not be satisfied with a superficial relation, but must work for that close working union which alone can cement the bond. The only League of Nations which seems to me immediately possible is a working union of all the branches of the Anglo-Saxon race, and this is within our grasp. Anglo-Saxon unity must precede any League.

It is to this bringing together of the British and Americans that we have most effectively addressed ourselves. We have been part and parcel of the British Service and have given it the best that we had to give. At the same time we have "with a decent respect for the opinions of others," maintained our own manners and customs, and have perhaps lived with somewhat greater freedom and worked and played a little harder than sound British custom would sanction. We have been a gathering place for all sorts and conditions of men, and we desire to acknowledge the debt we owe to Sir William Osler in helping forward this mixing of professional men and women from both sides of the Atlantic.

Sir STCLAIR THOMSON, joint honorary secretary with Mr. Douglas Harmer and Mr. J. Y. W. MacAlister of the Inter-Allied Fellowship of Medicine, then proposed the health of the Fellowship, describing it as "a very young person; in fact, a true war baby." The origin of the Fellowship, he said, was a visit to the United States last summer by Sir Arbuthnot Lane, Sir James Mackenzie, and Colonel H. A. Bruce, who on return brought the message that American medicine was looking to London to replace Berlin and Vienna as the Mecca for the English-speaking doctor. He continued:—

The objects of the Fellowship of Medicine might be grouped under four principal headings.

1. The coordination of all the resources of medical interest throughout this country, so as to make them readily available for demonstration and investigation.

2. Initiation of schemes of scientific entertainment. These would embrace the arranging of facilities for visits to, or courses of study in, the various clinics, laboratories, museums, and other medical institutions; the regular attendance on any one particular service, or course of lecture, or demonstration, and, in addition, the preparation of specially arranged addresses, demonstrations, or scientific visits.

3. Later on the Fellowship would be actively helpful in collecting and distributing information and in facilitating visits to overseas medical schools, meetings, and congresses; in being a centre through which the temporary occupation of professional chairs or exchange of professorships might be arranged.

4. The promotion of personal friendly intercourse between the members of the profession in this country and their brethren from overseas.

To promote these objects a centre had already been granted through the kindness of the Royal Society of Medicine at No. 1, Wimpole-street. These arrangements would be made to collect, file, and circulate information on all matters of medical interest. Rooms would be available for conferences, discussions, demonstrations, or exhibitions. In fact, the Fellowship of Medicine would act as a sort of central Cook's tourist office for travellers in the medical world.

The primary object of this association is not to arrange post-graduate study. This is the care of a separate association, which is also under theegis of Sir William Osler and with which there would be the most friendly co-operation. But post-graduates were particularly desirous of continuous and intensive training in one or more circumscribed departments of medicine. Now the Fellowship caters for all visitors, not only those seeking post-graduate classes, but also those wishing to study our medical history, our institutions and organisations, our hospitals, infirmaries, dispensaries, asylums, fever hospitals, lying-in institutions, nursing homes and sanatoria, or our State and municipal hygienic arrangements. We propose to help them to hear and join in the scientific medical life of this country and provide them with entertainments of medical interest. We will help them to see any one particular man operate or hear any special clinical demonstration; to work in any laboratory or study or in any library; to visit any asylum or investigate any system of drainage. We, ourselves, are so apt to work in water-tight compartments that we forget all about the wealth of this country in other matters of professional interest which lie outside our own practice or study.

Sir StClair Thomson went on to show that the organisation of a complete course of post-graduate teaching must require time, but that they had already been able through the help of State departments and the courtesy of the deans of the London medical schools to arrange opportunities for giving scientific hospitality to Dominion and American surgeons. The Director-General of the Army Medical

Service, Sir John Goodwin, had already co-operated by arranging with the Deputy Directors of Medical Service in command in the United Kingdom to institute facilities for mutual collaboration. The future co-ordination and arrangements for instituting a great post-graduate centre would require detailed, exacting, and continuous work, and Mr. Douglas Harmer was now associated with Mr. MacAlister, the first motive force of the movement, in perfecting their programme. Sir StClair Thomson concluded by referring to the fact that Lieutenant-Colonel Hugh Cabot was the direct descendant of the pilot, Sebastian Cabot, who used to sail out of Bristol city, and was the real discoverer of the Western Hemisphere.

Sir ARBUTHNOT LANE congratulated the Fellowship Society in its good fortune in being able to fix its paternity on Sir William Osler, who would make an ideal chairman.

"He is fortunate," he said, "in possessing all the progressive capacity of our trans-Atlantic brethren combined with the tenacity of the Briton. While, as occasionally happens, doubts may arise as to the paternity of the offspring, none can exist as to the maternity. This we owe, as we do so much else, to the originality, tact, indomitable energy and wisdom of our very old and beloved friend Mr. MacAlister. Wherever trouble arises Mr. MacAlister is the man who, in the most inconspicuous manner possible, has the capacity and ability to develop new ideas or to put things straight." Sir Arbuthnot Lane was certain that the young Fellowship would grow rapidly and would require no artificial food to hasten its growth. There was enough material in London and the provinces to produce a field of study that would compare very favourably with that in any part of the world. He would like to take this opportunity of expressing to the medical departments of our Dominions also the deep debt the profession wholly in the mother country owed them. He looked to them for invaluable help in making the new Fellowship the greatest possible success.

Sir JOHN GOODWIN, the Director-General of the Army Medical Service, said:—

I may perhaps claim a longer acquaintance and friendship with the Harvard Unit than most of those who are present to-night. I first had the pleasure of meeting this Unit when in France in 1915. I had the good fortune of knowing many of the officers intimately and saw much of their work, which was of an extremely high standard, and that standard has been consistently maintained throughout the war. I think I am correct in stating that more than 150,000 British soldiers have been treated and cared for by the Harvard Unit during its stay in France. May I ask you to think what that means in the way of actual assistance to our medical service, and may I suggest that, splendid as this record is, there is also something more, something not quite so tangible but equally valued by us, and that is the sentiment of brotherhood and affectionate feeling which was brought home to all of us when the Harvard Unit came over to France in 1915 to work with our armies and to succour our wounded. The members of the Harvard Unit endeared themselves to all of us, and we eagerly welcomed the many hundreds of medical officers and nurses who, immediately the United States entered the war, and many even before that date, volunteered for service with the British Armies and were of untold assistance to us, both in this country and in the theatre of war overseas.

I am sorry to say that there have been many casualties, many deaths; in view of a medical officer's duties in modern warfare this was inevitable, and the American officers were always eager for front line work; their honoured memories will remain with us for all time. One often hears discussion as to the international sentiment between America and ourselves during the past and in the present. With regard to this an old Arab proverb has very often occurred to me. I first came across it when studying Arabic in the East many years ago. The literal translation runs as follows:—

"I and my brother may differ, I and my brother might possibly quarrel, but—it is my brother and I together against the whole world."

The Harvard Unit is now returning to the United States, leaving behind it a splendid record of work performed and carrying with it the respect and affection of everyone who has ever met any of its members or seen its work. We wish them Godspeed and all possible happiness and prosperity in the future. In saying this I am conveying the thoughts and wishes of my whole service.

General G. L. FOSTER (Canada) said:—

It is with peculiar pleasure that I join with other speakers to-night in wishing the members of the Harvard Medical Unit God-speed on their homeward journey after three years of war labour. How well I recall their arrival in France during the summer of 1915; an event which meant to those of us from America—Canada being in America—that the United States would eventually join the Allies in the great struggle to uphold the right and liberties of mankind and to avenge the outraged women and children of Belgium and France. For the sending of such men as Harvard and other Universities of the United States sent to us in those early months was bound to have a far-reaching effect throughout the whole country, and awaken men and women in all walks of life to the justice of our cause. And now that the war is at an end, right having prevailed, we all shall sooner or later have returned to our several homes with the warmest feelings of friendship for those who suffered side by side with us these weary years. That friendship will ripen into a true fellowship of two of the world's greatest people to safeguard the world against future wars. The enemy and their leaders will receive a just judgment. We may hope that they will return to their senses, and cease from following that false Kultur which is even now sinking in the afternoon of history and will in time be swallowed up in the thick night of oblivion.

Sir W. WATSON CHEYNE, M.P., then proposed the health of Sir William Osler. He said:—

Sir William Osler is well known to the medical profession all over the world for his writings and speeches and his general learning, but he occupies a peculiarly important position in connexion with the project of an international Fellowship of Medicine, especially a Fellowship of

the English-speaking races, because he has held professorships in three great countries and universities. Beginning as Professor of Medicine in Canada, in the University of Montreal, he was invited to hold a similar position in the Johns Hopkins University in the United States of America, and in the fullness of time he was invited to bring his now ripe and varied experience to the Old Country and to take up a similar position in the venerable University of Oxford.

As you have heard to-night, Sir William Osler is the chairman of the committee which is working out one part of the scheme of this Fellowship—viz., that of rendering the wealth of clinical material which exists in this country available for post-graduate study as well as our great stores of pathology in various museums, of which the great type is the Royal College of Surgeons of England. But, as Sir St. Clair Thomson has pointed out to-night, the Fellowship to be successful should also have another side—viz., that which promotes friendly intercourse between the medical men of the various nations, of which the first attempt—and I think a highly successful attempt—is our meeting here to-night.

This is the age of young men, and we have it on very high authority that we cross the watershed of life about 40, and thereafter gradually go down the hill. I therefore ventured to suggest the other night that we might divide the work of this Fellowship according to the ages, the men up to 40 being engaged in imparting knowledge in the post-graduate work, while the men at a later period of life do more on the social and entertainment side. Of course, we could not draw a very hard-and-fast line, for some might think that the experience of the older men might be of help in the post-graduate work, while the vivacity and energy of the younger men might add to the joy and pleasure of the social side. So perhaps my suggestion was not quite seriously meant and may not be taken up. I ask you, ladies and gentlemen, to drink to the health of our most popular chairman, Sir William Osler.

Sir WILLIAM OSLER responded as follows:

After thanking the company for their kind response to the toast, the chairman said that among the advantages of advancing years was the knowledge one might have of three generations, and this was his position with regard to the profession of Boston, which may be called the *cortex cerebri* of the United States. Oliver Wendell Holmes's Brahmin class existed in a larger proportion in the profession of New England than in any part of the English speaking world. It was a peculiar pleasure to him to welcome the Harvard Unit, which contained grandsons of men whom he had known well in the seventies. Opposite to him sat Major George Cheever Shattuck, whose father, Frederick Cheever (a friend of student days in Germany and Professor of Medicine at Harvard) was the son of the distinguished George Cheyne, also a Professor of Medicine, the son of George Cheyne (*primus*), called after the famous English physician of that name, and son of Benjamin Shattuck—all of whom had practised medicine in Massachusetts—*caute, caste et probe*. Five generations of Warrens had served Harvard and the Massachusetts General Hospital—John, at present in the anatomical department, son of J. Collins, still alive and well and an honorary F.R.C.S., whose ancestors, Jonathan Mason, John Collins, and John Warren (the founder of the Harvard Medical School) were great figures in Boston. And there were many other medical families—as the Bowditchs, Jacksons, Bigelows—which had given an hereditary distinction, as rare as it is valuable in the profession of any city.

The New England spirit—the keen sense of right and wrong, and the desire to help, inspired Harvard to send this Unit long before America could enter the war as a united nation. And they were fortunate in the choice of the man who has had charge. Dr. J. William White, of Philadelphia, at the outbreak of war, and until his untimely death, fought the battle for the Allies against Germany in a way I hope we shall here never forget. And our chief guest and his brother, Dr. Richard Cabot, early entered the propaganda, but they did not confine their work to the Eastern States where sympathy was largely with the Allies, but they went West to the stronghold of German influence and held public meetings, sometimes in the face of stormy and even disorderly opposition. A rude little rhyme about the Cabots indicates their position in popular opinion:—

Here's to good old Boston,
The home of the bean and the cod,
Where the Cabots talk only with Lowells,
And the Lowells walk only with God.

The Unit returns with the grateful thanks of all classes of this country for the good work it has done in the relief of the British wounded; and it is a happy augury for the future of our Fellowship that its first official act has been to greet our brethren from overseas and to wish them a happy and a safe return.

It was allowed on all sides that the dinner should prove an admirable introduction to a great movement.

THE REPORT ON DUBLIN HOUSING.

THIS report, by Mr. P. C. Cowan, D.Sc., M.Inst.C.E., is of far more than local interest, since Dublin's housing problem fundamentally resembles that of many other towns, though perhaps few have so much leeway to make up before a tolerable standard of housing is reached. For in Dublin more than 40 per cent. of the population "urgently required improved housing at the end of 1913," and conditions are much worse now. Mr. Cowan has faced the whole situation in the bold and thorough way which those who know him would have expected.

The immediate task is to build 16,500 houses with the least possible delay, and Mr. Cowan suggests replies to the many vital questions involved in their erection. Who is to build and manage them? Where shall they be built? How many shall be built per acre? What size and type of house shall be built, and of what materials? His recommendations

on these matters are worthy of careful study, for they are based on the long experience and close thought of a man who combines a practical knowledge of building with a sympathetic insight into the human needs of the people to be housed. He realises that in all our schemes we must remember that we are building not only for the present but for the future. Wages are rising, and with them the standard of comfort. Houses *just good enough* to-day will not be good enough to-morrow.

"It would be a most grievous and irretrievable error," says Mr. Cowan, "to base the standard for new houses on the present homes, habits, and incomes of the poorer classes in Dublin. In many cases they only require the opportunity to respond to better environment, and it should be remembered that the standard of housing has risen steadily for many years, and that the houses erected now may have to serve at least two generations."

This is advice which all those who build under the present Government scheme will do well to remember. Mr. Cowan's recommendation that only 10 houses should be built per acre is quite in accord with up-to-date practice; but, as land near the centre of Dublin is very dear, he recognises that if such a limitation is observed the provision of adequate transit facilities would be a necessary corollary. The absence of such facilities, and the practice—soon, all must hope, to pass away—of starting work at 6 A.M., compel too many employees to live close to their work. Hence the anomaly to which Mr. Cowan draws attention—that "poor people, as a rule, live on dear land, and rich people on cheap land."

In connexion with transit, Mr. Cowan makes the interesting suggestion that it may eventually be provided free, just as roads and footpaths are. This is by no means as impracticable a policy as it may appear at first sight. The late Alderman William Thompson, in his "Housing Handbook Up to Date," states that:—

"The cost of equipping suburban land with trams may be taken at £25,000 per mile for initial capital outlay, or including working expenses and loan charges £5000 per mile per annum. This is on the assumption that there is in each direction a five-minute service for 12 hours each day, and a ten-minute service for another six hours, or a total of 131,400 car miles per annum, and that the inclusive cost is 9½d. per mile—an outside estimate.

"It is difficult to say how much land could be served by a mile of track, but reckoning 15 minutes' walk as the maximum distance on either side of the trams, we get an area of, say, 1760 by 2500 square yards, or 1000 acres, so the annual cost of free tramway equipment may be put at £5 per acre per annum, and this sum capitalised at 30 years means £150 per acre as the initial capital outlay per acre; that ought to be sufficient to convert comparatively inaccessible land into accessible building sites, with free trams running to and fro for 18 hours each day. Now assuming an average of only four houses to the acre, this means less than 6d. per house per week rent, to include free travel."

This is considerably less than would be saved in rent by living away from the town, not to speak of the advantage of having a house surrounded by a garden instead of being wedged into a sordid street.

Almost the whole of Mr. Cowan's report is full of excellent suggestions and wise counsel. But in considering the number of bedrooms which should be provided per house he adopts a point of view which is curiously at variance with his general attitude. On the strength of some very unconvincing statistics he recommends that no less than 60 per cent. of the houses built should only have two bedrooms. Here he runs counter to all modern ideas; unquestionably it would be a catastrophe if his advice were followed. We positively *must* get away from the two-bedroomed house, which, when occupied by a family is quite inadequate, whether to meet the requirements of health or decency. One of the serious difficulties that we have to face to-day is that more than half the houses in the British Isles have only two bedrooms or less, whereas, judging from the Census returns, considerably over a million of these should have three bedrooms or more in order to meet the minimum housing requirements of their occupants. Surely, not a shadow of a case can be made out for adding to the number of two-bedroomed houses, save in the rarest cases.

But this is only a momentary "lapse from grace," and Mr. Cowan's report is a fine piece of work, and should be widely read. The plans at the end, illustrating the houses which have been erected by various Irish municipalities, should, however, be studied with discretion, since obviously only some of them are meant to be examples, while the others are warnings against what to avoid.

Correspondence.

"Audi alteram partem."

THE FUTURE OF THE AMERICAN RED CROSS IN PARIS.

To the Editor of THE LANCET.

SIR,—A permanent Chapter of the American Red Cross has been formed in Paris, known as the Paris District Chapter, and of said Chapter I am the chairman. It is proposed that this Chapter shall be the permanent organisation of the American National Red Cross in France, and its functions will be to carry on to a conclusion the work inaugurated by the American Red Cross after the Commission to France which during the war has been in charge of said work has ceased to exist. After the completion of this work it is proposed that the Chapter shall continue to perform all functions ordinarily performed by a Chapter of the American National Red Cross. It is impossible at this time to foresee just what the character of this work will be, but among other things it may involve the care of the graves of American soldiers and sailors buried in France, and also to have an organisation constituted and capable of carrying on any work that it is proper that the Red Cross should do.

I am, Sir, yours faithfully,

GURNEY E. NEWLIN,

Major, A.R.C., Chairman, Paris District Chapter.

4, Place de la Concorde, Paris, Jan. 17th, 1919.

CAUSES AND INCIDENCE OF DENTAL CARIES.

To the Editor of THE LANCET.

SIR,—Dr. Harry Campbell's courteous reply to my inquiry is somewhat confusing. In your issue of Jan. 4th he states—

"I have again and again referred to the prosaic fact that there are among the inhabitants of this country 200 million carious teeth, as many alveolar abscesses (pyorrhoea alveolaris), and some 30 million root abscesses."

I ventured to ask for evidence of this "prosaic fact," and Dr. Campbell replies by stating that—

"Taking the population of the United Kingdom as 45 millions, this, according to my estimate, implies for each individual $\frac{4}{5}$ carious teeth, $\frac{4}{5}$ alveolar abscesses, and 2 root abscesses for every three persons. Does this estimate strike Mr. Pedley as excessive?"

To Dr. Campbell's question I answer frankly: very excessive! Not in accordance with my experience; but that is only my opinion. Surely calculations based upon such estimates are not facts. *Facts are truths*, and can only be regarded as such when supported by irrefutable evidence. Here is an illustration. Dr. Campbell quotes extracts from Dr. James Wheatley's report of 1914 to the education committee of the Salop County Council as to the prevalence of dental caries among elementary school children, and if it is remembered that the percentages include temporary teeth as well as permanent teeth I entirely agree, because it accords with the evidence of the Schools Committee of the British Dental Association, and it has been amply proved by 1000 school medical officers during the past ten years, as recorded in the annual reports of the Chief Medical Officer to the Board of Education. One brief quotation will suffice. On p. 29 of the 1915 report it is stated—

"The proportion of defective teeth including all degrees of defect is higher than in any other malady, and often exceeds 70 or 80 per cent."

Curiously enough, Dr. Campbell seems to refute part of his estimate, for he writes:—

"When we come to examine adults we find that a considerable proportion of carious teeth have been extracted owing to the trouble they have caused, so that the number of carious teeth in a given mouth does not represent the number of permanent teeth which have become carious within it."

Either the 45 million inhabitants have the $\frac{4}{5}$ carious teeth or they have not.

With regard to the $\frac{4}{5}$ alveolar abscesses (pyorrhoea alveolaris), these diseases are not identical. Alveolar abscesses are in the majority of cases root abscesses. Pyorrhoea alveolaris is suppuration at the necks of the teeth with slow destruction of the alveolus. The dental surgeon differentiates them, as the physician does pneumonia from pleurisy. Therefore the $\frac{4}{5}$ alveolar abscesses, and the two root abscesses for every three persons, may be added together. I do not understand Dr. Campbell's estimate of pyorrhoea alveolaris. His endeavour to find figures for me

in 17 men "hastily examined" reminds me that, like many of my colleagues, I have examined during the past four and a half years quite a large number of soldiers' and sailors' mouths. I believe it is possible to identify, clinically, four or five different forms of suppurative inflammation of the gums which at first might be described as pyorrhoea alveolaris, but which heal up under appropriate treatment without the loss of any teeth.

In conclusion, I deplore the extent of dental caries and its effects, but I think much harm may be done by loose statements and exaggerated ideas. Experience has taught me that there is no royal road to the prevention of dental diseases. To believe that our nation will alter its diet to save its teeth is chimerical. The chief safeguards are habitual cleanliness, systematic inspection, and early treatment. Much has been done during the past 20 years to help the children in our residential Poor-law schools, and an excellent beginning has been made during the past 10 years by the establishment of 300 school dental treatment centres for the children of the elementary schools. Only when skilled assistance is available for every child in the country can we hope to have a nation with clean and healthy mouths.

I am, Sir, yours faithfully,

R. DENISON PEDLEY.

Railway Approach, London Bridge, S.E., Jan. 20th, 1919.

THE DREAMS OF THE TERROR-NEUROSIS.

To the Editor of THE LANCET.

SIR,—Dr. C. S. Myers (Lieutenant-Colonel, R.A.M.C. (T.O.)), in his article published in your issue of Jan. 11th, draws attention to the dreams of the terror-neurosis encountered in warfare. He raises certain points of interest, in particular as to how such dreams subside as the neurosis improves; whether there is any gradual intrusion into the incidents of warfare characteristic of the terror-dream by those of civil life.

In my experience there is rarely any such history. Patients who have suffered severely from terror-dreams during the earlier phases of their disability associate their improvement with the subsidence, not of the terrifying incidents only, but of dreaming altogether. In the majority of cases of the terror-neurosis patients in the period of cure cease to dream at all, and this is of interest in that it agrees with what the same patients so often say in reply to the questions as to the nature of their dreams before they broke down, before they were invalided, that is to say. For the most part they are consistent in saying that they did not dream at all, and certainly had had no frightening dreams.

There would appear, therefore, to be no period before the dysthymic somatic symptoms become obtrusive in which there are terrifying dreams; the somatic bodily symptoms precede the dream. At first sight this may seem to be curious; it might have been thought that when the conscious intelligence was in abeyance during sleep any emotional tone that was experienced in the waking state and was not allowed free play would make itself felt. The fact that this is not so in many cases may be associated perhaps with the intensity of the "blocking" to which it was subjected during the waking hours, the intensity being so great that it "overflows" into the sleeping state with a similar result, and is, of course, responsible for the terminal somatic symptoms of the neurosis. Once the somatic symptoms have made their appearance and the patient is in a position in which there is no further need for the emotion to be blocked, then fear does appear, and, in severe cases, not only in the dream but in the periods of wakefulness as well. Then we do see the effect of intelligent control, for as the case improves the fear leaves the patient during the day but persists during sleep when such control is in abeyance. In the course of time the control exerted during wakefulness overflows into the period of sleep and lessens the intensity of the dream. Possibly the powerful efforts made by the patient to control himself consciously operates in excess and stops dreaming altogether for a time.

We might almost go so far as to say that the patient who did experience fear in his dreams before the onset of somatic symptoms would not suffer severely when the neurosis was formed; the essential blocking of the emotion of fear in his case not being of any great intensity, not sufficiently intense

to overflow into his sleep and prevent the terror-dream, and therefore not sufficiently intense to bring about the neurosis in any degree of severity.—I am, Sir, yours faithfully,
Manchester, Jan. 14th, 1919.

DONALD E. CORE.

ENCEPHALITIS LETHARGICA AND TYPHUS.

To the Editor of THE LANCET.

SIR,—I have been struck by the close clinical resemblance which encephalitis lethargica as described in your columns by Dr. A. S. McNalty and Lieutenant-Colonel A. J. Hall bears to typhus fever, a disease little familiar to the medical profession in England except in the pages of such a book as Vincent and Muratet in the "Military Medical Manual" Series. The onset, the rash, constipation, the nervous symptoms of both organic and hysterical nature, the stupor, the inability to protrude the tongue (Remlinger's sign in typhus, hypoglossal palsy mentioned by Dr. F. G. Crookshank), and tremors are some of the striking points these diseases have in common. Epistaxis, however, has not, so far as I know, been mentioned as occurring in lethargic encephalitis; the experience of most medical officers serving with the E.E.F. is that epistaxis is also rare in typhus, contrary to the usual teaching. I inquired recently about this point from an Egyptian medical officer who had seen over 1000 cases of typhus while serving with the Turkish Army; in no instance did he observe epistaxis.

On the pathological side the cause of both diseases is unknown, but an increase of the cellular content of the cerebro-spinal fluid has been found by Major C. R. Box in lethargic encephalitis, and by Devaux in typhus in Roumania, although it is to be noted that an excess of lymphocytes was described by the former, and of polynuclear leucocytes by the latter. Finally, the low mortality of lethargic encephalitis does not contradict this thesis, for typhus mortality is based on epidemics associated with starvation, bad hygienic surroundings, and lack of proper hospital accommodation; further, a mild form of typhus (*Typhus levisimus*) has been recognised abroad for some time.

I am, Sir, yours faithfully,

H. L. C. NOEL,

— Egyptian Hospital, E.E.F.

Captain, R.A.M.C.

INVALIDISM FOR 15 YEARS THROUGH NASAL BLOCKAGE.

To the Editor of THE LANCET.

SIR,—In his article in THE LANCET of Dec. 14th, 1918, Dr. G. A. Sutherland writes that men with cardio-vascular debility "stand cold weather badly." Last winter I saw a B3 man who told me he dreaded the cold weather. He always kept several pairs of boots going and wore very thick socks, and in them he placed felt soles. Damp boots and socks were a horror to him. He said he was an invalid and had a bad circulation. By chance my attention was drawn to his nose, and I found his septum was deflected to the left side. He refused an operation. I noticed his *alæ nasi* did not move, so I suggested he should practise nasal respiration. In a week the action had become automatic, and he told me with rapture he had passed from invalidism to strength. He found that he could wear the same pair of boots every day, and even do without socks. This latter was a great advantage, as it saved him darning socks! He told me he noticed that on a cold day the air passing into his now opened-up nostrils would send his blood shooting to the tips of his toes and fingers and acted like champagne on his mind. He said the cold weather he used to dread now acted as a tonic, and he revelled in it. The only alteration in his manner of life that brought this change about was nasal respiration, which kept his nasal passage on left side patent.

I am, Sir, yours faithfully,

Dec. 20th, 1918.

CHAS. J. HILL AITKEN, M.D. Edin.

PHTHISIS IN FACTORY AND WORKSHOP.

To the Editor of THE LANCET.

SIR,—May I write a few words in answer to Sir G. Archdall Reid (THE LANCET, Dec. 28th, 1918)?

1. I consider tuberculosis a contagious disease produced by the *Bacillus tuberculosis*.

2. Even though practically everybody is exposed to the infection, only a relatively small number of human beings

die from it—only predisposed people. Naegeli (500 cases of post-mortem examination) found that 97 per cent. of the patients dying in hospital (most of them living in towns) showed evidence that tubercular infection had at one time taken place.

3. Predisposition is either hereditary or acquired.

4. Amongst the most powerful causes of predisposition, hereditary or acquired, is alcoholism.

5. We know very well that civilisation brings alcohol in its train, and that many primitive races have disappeared because they have taken to drinking "fire water."

6. But we must add also that civilisation has brought new diseases to those populations—measles, tuberculosis, syphilis.

7. Dr. Ed. Bertholet has made the following observation. Up to 25 years of age practically all his cases of death from tuberculosis occurred amongst abstainers or very moderate drinkers; over 25 years practically all the cases were chronic alcoholics. I do not know whether his researches have been confirmed elsewhere.

8. In my letter of Dec. 6th (THE LANCET, Dec. 14th, 1918) I was trying to suggest a possible explanation of the great difference in mortality from tuberculosis between men and women under practically similar living conditions, the only difference between them being what Dr. W. O. Sullivan has called "industrial alcoholism" in the men.

I should be very glad to know if Sir G. Archdall Reid and Professor Benjamin Moore have other explanations or hypotheses to offer regarding these facts, my opinion being that women are certainly living, in their homes, under conditions more favourable to contracting tuberculosis, and to death from it, than their husbands.

I am, Sir, yours faithfully,

M. F. BOULENGER.

Darenth Industrial Colony, Dartford, Kent, Jan. 10th, 1919.

THE LEUCOCYTE COUNT IN INFLUENZA.

To the Editor of THE LANCET.

SIR,—I have seen a few references to the blood in influenza in papers published on the recent epidemic, and they all confirmed past experience. So far as they go my results do the same, but I made no total counts. Obviously this omission could not introduce abnormal cells into my films or take away from them normal forms which they did not contain. And in these respects alone has my experience been exceptional. Excluding moribund and mild cases, it is based on the examination of three moderately severe uncomplicated cases which made good recoveries, and on three cases with severe bronchitic or pneumonic complications which died after 6–10 days of illness.

Briefly, in seven examinations of the fatal cases I saw no eosinophile, and in the other cases these cells disappeared during the height of the disease. Again, in every one of the six cases plasma cells were seen on the fourth day or later. Usually 1 or 2 per cent. were present, but in one of the fatal cases there were 5 per cent. on the sixth day—four days before death. I have never seen anything approaching this in the adult, and it is no exaggeration to call it a phlogocytosis.

In pneumonia and typhoid the eosinopenia is well known. In whooping-cough I have seen 3 per cent. of plasma cells in children. But in a woman of 46, previously healthy, 5 per cent. in influenza seems worthy of record.

I am, Sir, yours faithfully,

Baling, W., Jan. 19th, 1919.

R. CRAIK, M.D. Glasg.

METRRORRHAGIA IN INFLUENZA.

To the Editor of THE LANCET.

SIR,—The very complete and excellent account of the last influenza epidemic by Dr. Adolphe Abrahams, Dr. N. Hallows, and Dr. H. French in THE LANCET of Jan. 4th, seems to me to require one slight emendation from the clinical side, in which only I am able to criticise. It is said that in the hæmorrhages nothing abnormal was found from the uterus. If the authors will make a few further inquiries they will find that while epistaxis was common in males, it was rare in females, but these latter in a large proportion had menses coming on during the fever and before the proper time. It was at least so in this neighbourhood, and not alone in my experience. In two instances definite miscarriages

occurred. One pregnancy terminated three weeks before time on the second day of illness and the influenza ran an ordinary course afterwards of about a week, the mother nursing her baby all the time. One patient aborted at seven months about 12 hours after lung symptoms with cyanosis had appeared; the child was stillborn and the mother was dead about 16 hours afterwards, the third death from the septicæmia in that house and family. It seemed that epistaxis or metrorrhagia always denoted a bad or prolonged attack.

Another point was that a high temperature did not mean a severe attack; three cases had an ascertained temperature about the second or third day of 106° F. and they all came to normal in an average time and afterwards recovered quickly. They were all in girls and in families who kept clinical thermometers; probably there were others, for I am glad to say only a minority of my patients indulge in the luxury of thermometers.

I am, Sir, yours faithfully,
St. Ives, Huntingdon, Jan. 6th, 1919. W. R. GROVE.

WAR DEAFNESS.

To the Editor of THE LANCET.

SIR,—In the contribution of Dr. O. S. Myers to the study of shell shock in your issue of Jan. 11th there occurs the following statement:—

"Moreover, every physician of experience must have met, with patients suffering from functional deafness whose sleep has not been in the least disturbed by the loudest noises."

May I venture to ask Dr. Myers whether he or any observer in whom he has confidence has recorded any number of such cases? So far as I am aware, many of us believe that functional deafness is extremely rare, and that it can only be diagnosed with certainty after recovery has taken place. For my part, were the question addressed to me, I should have to answer it with a decided negative.

I am, Sir, yours faithfully,
Jan. 17th, 1919. P. McBRIDE.

THE "SPECTRUM" OF EPILEPSY.

To the Editor of THE LANCET.

SIR,—The weirdness of some of the fits of some of the men discharged from the Army as epileptic makes prominent in one's mind the ever-present question: Whether there is a boundary line between epilepsy and hysteria? To be always able to tell hysteria from epilepsy suggests inexperience; it is easier to the medical student than to the epileptologist. The student can quote a text-book. The fact may be that there is no dividing line. As we know nothing about epilepsy—though much about epileptics—and the physiology of the nervous system is still an infant, fanciful explanations are still permissible. We may fancy that there are three diseases: malingering, which is an affair of the consciousness, hysteria (rampant egoism of the subliminal self), which is an affair of the subconsciousness, and epilepsy, which is an affair of the unconsciousness. If that be so, there are no dividing lines between the three diseases. Epilepsy shades into hysteria and hysteria into shamming, as the colours shade into one another in the spectrum. It might tend to promote scientific treatment of convulsive diseases if the physician would make a spectrum-like chart of malingering, hysteria, and epilepsy, and attempt to plot on it the individual fits of his particular patient.

I am, Sir, yours faithfully,
ALAN McDOUGALL,
Director of the David Lewis Epileptic Colony.
Sandle Bridge, Cheshire, Jan. 19th, 1919.

ISAAC DOBRÉE CHEPMELL.

To the Editor of THE LANCET.

SIR,—The death of Dr. I. D. Chepmell was briefly noted in THE LANCET of Jan. 4th. He was one of the oldest members of the profession, but having left London many years since his life is familiar only to a few. Born in Guernsey in 1828, the second son of Captain Charles Chepmell, he was at first educated at Elizabeth College, Guernsey, and later at King's College, London. In 1850 he took the L.S.A. and then travelled in France and Italy with Lord Holland. He became master of French and Italian, thus laying the foundation of his future professional success. In 1859 he married and settled in Paris, where he continued

to practise till the Franco-German War. While in Paris, where he became physician to the Galignani Hospital, he had many distinguished Frenchmen as patients and was Foreign Correspondent to THE LANCET for many years. Settling in London in 1871, he practised there until his sight failed as the result of glaucoma. Here also he continued to advise many distinguished foreigners. The Empress Eugénie was his patient and friend. A skilful practitioner and a gracious personage, he had many warm attachments.

Chepmell was a keen and expert swordsman, and several of his London colleagues were induced by his example to take up fencing. Of his two sons one became a member of the medical profession, the other entered the Army, and three of his grandsons have fallen during the war.

I am, Sir, yours faithfully,
Devonshire-place, W., Jan. 20th, 1919. GEORGE H. SAVAGE.

AMOEBC DYSENTERY CARRIERS: A CORRECTION.

To the Editor of THE LANCET.

SIR,—In my recent article on amoebic dysentery carriers among new entries to the Royal Navy (THE LANCET, Jan. 11th) I made the statement that *Lambliæ* "is not known to be a normal parasite of the cat." This appears to have been erroneous. Neumann, in "Parasites et Maladies Parasitaires du Chien et du Chat" (Paris, 1914), mentions the cat among the list of hosts from which this parasite has been recorded.

I am, Sir, yours faithfully,
Jan. 20th, 1919. H. A. BAYLIS.

PLACE AUX EMBUSQUÉS?

To the Editor of THE LANCET.

SIR,—An open appointment as medical officer to the Corporation of Birmingham Pensioners' Hospital was advertised, preference being given to "senior men having recent hospital experience." A Lieutenant-Colonel, a Major, and three Captains, Royal Army Medical Corps, all with war service, were candidates. The appointment was given to a young recently qualified man who has never served his country. The undersigned gave up a good position in 1914 to do his bit. He has served continuously in four hospitals in Egypt and France since then, and was foolish enough to hope that such war experience would be taken into consideration in making the appointment.

Demobilisation of temporary Royal Army Medical Corps officers is imminent, and it is a great source of anxiety to many men whose practices are now derelict, how are they to provide for the future of those dependent upon them.

I am, Sir, yours faithfully,
A. W. COMBER, R.A.M.C.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

Major R. G. Archibald, D.S.O., is placed on the half-pay list under the provisions of Article 307 (7), R.W. for Pay and Promotion.

Temporary Captains relinquishing the acting rank of Major on re-posting: J. H. Hood, A. M. Crawford, J. Greene, A. Manuel, W. H. D. Smith, R. C. Alexander.

Temp. Capt. G. G. Buchanan to be acting Major whilst specially employed.

Temporary Lieutenants to be temporary Captains: H. M. Berry, J. L. Schilling, T. A. Fall, A. Robin, R. H. Vercoe, H. M. Birkett, C. A. A. Lever, S. Johnson, L. W. Huellin, H. Gibson, C. Clyne, T. J. Cobbe, P. Savill, G. R. Jeffrey, W. B. Valle, E. Gandy, E. O. Hughes, A. P. Hall, J. P. O'Mahony, G. B. Proctor, J. Mathewson, W. J. B. Lavery, C. M. Elliston, E. G. Bunbury, J. C. Duncanson, C. I. McLaren, C. Dean, H. M. Grace, G. O. M. Davis, E. R. Griffiths, G. A. Thompson, D. C. McCormick, C. G. Burton, R. N. Porter, B. A. I. Peters, F. J. Cairns, J. B. Taylor, I. L. MacInnes, V. J. A. Wilson, C. E. F. Salt, F. King, S. S. Rosebery, G. Young, W. H. A. Elliott, H. S. Dixon.

Temp. Hon. Lieut. H. A. Haskell to be temporary Honorary Captain. Officers relinquishing their commissions: Temp. Col. O. Richards, C.M.G., D.S.O., A.M.S., and retains the rank of Colonel. Temp. Lieut.-Col. Sir J. W. Barrett, K.B.E., C.B., C.M.G., and retains the rank of Lieutenant-Colonel. Temp. Hon. Lieut.-Col. H. A. Powell and G. Dreyer. Temp. Majors W. M. Robson and A. J. Cleveland and retain the rank of Major. The following retain the rank of Major: Temp. Capts. (acting Majors) F. B. Young, A. Richmond, H. H. Warren, W. B. Dickie, E. R. Grellett, W. M. Badenoch, R. S. Renton, J. L. Menzies, Temp. Capts. J. S. B-llas, J. B. McCabe, J. M. Glasse, A. R. Jackson, J. H. Hebb. To retain the rank of Captain: Temp. Capts. G. W. Ancrum, H. E. Brown, R. N. Porter, H. G. Rloe, G. H. Rodolph, G. B. Moffatt, O. Y. Flewitt, J. Forrest, A. G. J. Thompson, E. W. B. Ruxton, A. D. Hamilton, H. Smurthwaite, S. H. Ryan, D. C. McArdle, A.

Dingwall, J. L. Johnston, J. T. Gunn, A. B. Laidlaw, W. W. Wood, J. A. H. White, A. Dixon, J. Ferguson, R. H. S. Torney, D. J. McAfee, W. B. Watson, T. A. Matthews, G. E. Oates, J. L. McCann, D. J. Foley, C. Watson, L. J. Weatherbe, W. Warburton, J. H. Morris-Jones, J. Fletcher, T. E. Flitcroft, S. McNair, F. W. Perry, A. H. Murch, W. H. Best, G. R. Phillips, J. A. V. Matthews, J. Reid, M. Golding, J. C. Wootton, R. W. Greator, A. S. Wilson, F. S. Adams, D. T. H. Croly, F. Barnes, T. Henderson, B. H. Worth, S. C. H. Bent, M. W. Baker, H. Walker, A. H. B. Hartford, T. N. Bride, G. Unsworth, D. Mann, H. P. Wright, R. E. Whitting, J. Morris, G. T. Bogle, A. F. Waterhouse, P. W. L. Camps, J. Steward, G. P. Young, M. S. Selser, V. Lloyd-Evans, A. Simpson, P. E. MacNaught, R. F. Emsinon, A. G. Wilson, C. J. Nicholson, H. Tren, G. Graham, J. Clark, F. M. H. Sanderson, T. B. McKendrick, G. H. C. Lumsden, A. Manuel (acting Major), E. Wight, G. W. Thompson, J. Cameron, H. D. Haworth, W. B. Hendry, E. A. B. Poole, H. F. Warner, T. B. Johnston, K. Fraser, R. Appleton, D. J. McLeish, O. Smith, P. de S. Smith, R. C. Harkness (acting Major), J. C. Mead, R. O. Smyth, B. L. Hutchence, A. S. Bradley, W. H. Blakemore, J. T. Carson, S. S. Brook, W. P. Lowe, R. B. Johnston, G. H. Davy, W. C. Fowler, T. F. Murphy, H. E. Middlebrooke, J. Holland, C. Barnard, W. V. Naish, G. Stoddart, L. Bromley, H. Upcott, G. P. Humphry, G. W. Curtis, A. J. Hutton, A. J. McConnell, H. Wildas, A. Mason, E. J. Morton, R. Edridge, H. M. Joseph, F. W. Ritson, A. G. Henderson, D. A. Dewar, R. E. Walker, A. Ferguson, A. Bryans, A. H. Mountcastle, J. H. Trench, R. J. Bonis, D. A. Powell, E. F. R. Alford, J. V. Cope, G. C. Cossar, D. W. Daniels, G. B. Moffatt, H. S. Millar, H. R. Ramsbotham, C. A. R. Gatley, E. W. Milne, J. Wright, J. Proctor, Temp. Hon. Capt. R. A. Holmes and C. E. S. Jackson retain the hon. rank of Captain. Temporary Lieutenants retaining the rank of Lieutenant: W. Q. Wood, D. Robertson, J. Craig, R. Price, F. J. Power, C. E. Elliston, B. Hutcherson. Temporary Lieutenants: A. A. Hall, Temp. Hon. Lieut. H. A. Lownds. The undermentioned on transfer to R.A.F.: Temp. Major (acting Lieut.-Col.) J. L. Birley; Temp. Capt. (acting Major) J. H. Porter; Temp. Capt. J. H. Cooke, P. H. Young, W. S. T. Connell, L. W. Shelley, W. J. McKeand, C. W. W. James, A. G. H. Moore, F. A. Hampton, C. H. Thompson, C. K. Attlee, C. F. Graves, J. Chambre, W. Waugh, T. N. Wilthew, W. B. Dove, A. G. H. Smart, N. C. Graham, E. W. Craig, D. H. Fraser, G. Cranston, J. Freeman, W. H. Cam; Temp. Lieut. G. D. M. Beaton.

SPECIAL RESERVE OF OFFICERS.
Lieut. G. N. Groves to be Captain.

TERRITORIAL FORCE.
Major (acting Lieut.-Col.) J. Evans relinquishes his acting rank on ceasing to command a Field Ambulance.
Capt. (acting Major) H. Drummond relinquishes his commission on account of ill-health contracted on active service, and is granted the rank of Major.

Capt. A. E. Raine relinquishes his commission on account of ill-health contracted on active service, and retains the rank of Captain.
2nd Western General Hospital: Capt. C. P. Lepage reverts to the list of officers available on mobilisation and is restored to the establishment.
1st Eastern General Hospital: Major A. Cooke is restored to the establishment.

TERRITORIAL FORCE RESERVE.
To be Majors: Major (acting Lieut.-Col.) A. E. Hodder, from 3rd North Midland Field Ambulance; Major W. M. Mackay, from Attached to Units other than Medical Units; Major W. D. Milbanke, from Attached to Units other than Medical Units; Major A. B. Murray, from Attached to Units other than Medical Units; Major (acting Lieut.-Col.) A. Callam, from 2nd East Lancs. Field Ambulance; Major H. E. Corbin, from the General List.

To be Captains: Capt. R. D. Cran, F. Harvey, A. N. Crawford, John Livingston, G. Eustace, J. D. Lickley, N. G. H. Salmon, M. Wilks, O. Teichmann, from Attached to Units other than Medical Units; Capt. (acting Major) T. H. Peyton, from 1st Home Counties Field Ambulance; Capt. H. C. H. Bracey, from General List; Capt. A. J. Campbell, from South Wales Mounted Brigade Field Ambulance; Capt. J. Carroll, from 3rd Welsh Field Ambulance; Capt. C. R. Crowther, from 2nd Wessex Field Ambulance; Capt. A. C. C. Lawrence, from 2nd Northern Field Ambulance; Capt. (acting Major) G. Potts, from Attached to Units other than Medical Units; Capt. (acting Major) A. C. Watkin, from 2nd Home Counties Field Ambulance; Capt. (acting Major) S. McCausland, from 1st West Lancs. Field Ambulance; Capt. J. Penston, from Wessex Casualty Clearing Station; Capt. W. S. Forbes, from 1st London Casualty Clearing Station; Capt. W. W. J. Lawson, 3rd West Riding Field Ambulance; Capt. C. H. Lilley, from 2nd London Sanitary Company; Capt. A. V. Maybury, from 3rd Wessex Field Ambulance; Capt. C. G. Meade, from Yorkshire Mounted Brigade Field Ambulance; Capt. R. W. Nevill, from 1st Northampton Field Ambulance; Capt. (acting Major) W. Sneddon, from 3rd West Riding Field Ambulance; Capt. (acting Major) J. L. M. Symns, from 1st East Anglian Field Ambulance; Capt. (acting Major) R. M. Vick, from 3rd London Field Ambulance.

ROYAL AIR FORCE.

Medical Branch.—Major A. V. J. Richardson to be acting Lieutenant-Colonel whilst employed as Lieutenant-Colonel. L. S. Goss (Surgeon-Lieutenant, R.N.) is granted a temporary commission as Captain. Capt. J. A. Watson, Capt. H. Greenwood, Capt. E. J. Boyd (Surgeon, R.N.), Major-Gen. R. O. Munday, C.B. (retains the rank of Major-General), Capt. H. J. Shanley (Captain, R.A.M.C., T.F.), and Capt. J. A. Wilson relinquish their commissions on ceasing to be employed. Capt. A. E. McCulloch and Lieut.-Col. H. J. Hadden (Fleet Surgeon, R.N.) relinquish their commissions at their own request.

THE Swiney prize of the Royal Society of Arts has been awarded for the second time to Dr. Charles A. Mercier for a thesis on jurisprudence.

Dr. W. H. R. Rivers has been appointed *Prælector* in Natural Sciences at St. John's College, Cambridge, where he already holds a Fellowship.

The War and After.

THE CASUALTY LIST.

The names of the following medical officers appear among the casualties announced since our last issue:—

Died.

Surg.-Lieut.-Com. M. H. Langford, D.S.O., R.N., was a student at Middlesex Hospital and qualified in 1909. He joined the Royal Navy shortly afterwards.
Surg.-Lieut. M. Meehan, R.N., qualified in Ireland in 1912 and shortly afterwards joined the Royal Navy.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualty among the sons of medical men is reported:—

Lieut. J. Clarke-Morris, West Riding Regiment and R.A.F., accidentally killed whilst flying in France, youngest son of the late Dr. K. Clarke-Morris, of Blackheath, Kent.

THE HONOURS LIST.

The following awards to medical officers in recognition of their gallantry and devotion to duty in the field are announced:—

Bar to Distinguished Service Order.

Lieut.-Col. ANSON SCOTT DONALDSON, D.S.O., 3rd Fd. Amb. Can. A.M.C.—For conspicuous gallantry and devotion to duty. This officer was in charge of the evacuation of the forward area, and showed great initiative in establishing dressing stations and collecting posts directly in rear of the advancing infantry. He kept in touch with the battalion and succeeded in evacuating the casualties almost as soon as they occurred, in spite of heavy machine-gun and shell fire.

Lieut.-Col. THOMAS JOSEPH FRANCIS MURPHY, D.S.O., 6th Fd. Amb. Can. A.M.C.—During an attack there were several wounded cases whose evacuation was being held up by the intense enemy barrage. This officer then brought up two motor ambulances, which he left some distance in rear, and came up with his runner to the village and searched for the regimental aid-post, which he found after much difficulty, all the time exposed to heavy fire himself, as he passed several times through the enemy barrage and machine-gun fire. It was through his utter disregard of personal danger that the wounded were safely cleared and many lives saved.

Distinguished Service Order.

Major JOHN CHARLES CAMPBELL, 7th Fd. Amb. Austr. A.M.C.—For conspicuous gallantry and devotion to duty. This officer was in charge of stretcher-bearers, evacuating all wounded from the right sector of the advance throughout five days' fighting. He kept close behind the infantry and kept in touch with the various medical officers under constant heavy fire. One night a direct hit completely demolished his aid-post, but he got his men to a place of safety and continued the evacuation of the wounded. He superintended the work for five days continuously with great courage and persistence, setting a fine example to all under him.

Capt. (acting Lieut.-Col.) THOMAS HENRY SCOTT, M.C., 14th Fd. Amb.—For conspicuous gallantry and devotion to duty. When the vicinity of his advanced dressing station was being heavily shelled, it was due to his coolness and able management that a number of stretcher and walking cases were evacuated quickly and smoothly. His foresight and organisation were mainly responsible for the very large numbers of officers and men successfully evacuated during this period under most difficult conditions.

Capt. (temp. Major) WILLIAM DUNCAN STURROCK.—For conspicuous gallantry and devotion to duty, when the main surgical ward and operating tent of a field ambulance were wrecked by shell fire, one officer and two other ranks being wounded. He very quickly put matters right, and, owing to the excellent arrangements made by him throughout the operations, the wounded, in spite of difficult country and lack of roads, were very rapidly collected and evacuated.

Major (acting Lieut.-Col.) GEORGE GRANT TABUTEAU, No. 1 Fd. Amb.—For conspicuous gallantry and devotion to duty in supervising the evacuation of casualties during three days' operations under heavy shell fire. He maintained a chain of medical posts in close touch with the battalions of his brigade, and the rapid removal of the wounded was due to his coolness and untiring energy, which inspired his officers and men with confidence.

Second Bar to Military Cross.

Temp. Capt. (acting Major) JOHN SAMUEL LEVIS, M.C., 51st Fd. Amb.—For conspicuous gallantry and devotion to duty. During an attack, when the regimental aid-posts were under direct enemy observation, this officer, approaching them over ground swept by machine-gun fire, made arrangements for the wounded to be evacuated by a safer route. He was indefatigable in the day in keeping touch with the aid-posts as they moved forward, and during the night took stretcher-bearers up to the front line to search for wounded.

Capt. (acting Major) CAMPBELL MCNEIL MCCORMACK, M.C., 15th Fd. Amb.—For conspicuous gallantry and devotion to duty. During various attacks this officer supervised the collecting of wounded over a large part of the divisional front. He closely followed the advancing troops with his stretcher-bearers, evacuating the wounded skilfully and speedily. On one occasion during a retirement he personally, under heavy fire, reconnoitred the ground where the wounded lay, and by his dispositions of the stretcher-bearers undoubtedly saved their lives and the lives of many of the wounded.

Temp. Capt. CHARLES GORDON TIMMS, M.C., attd. 7th Bn., R. Fus.—For conspicuous gallantry and devotion to duty. During a counter-attack this officer went forward from battalion headquarters and effected several rescues of seriously wounded men, conducting them personally to the lines. Throughout the week's fighting he worked night and day, and the manner in which he disposed of stretcher cases under heavy fire was admirable.

Bar to Military Cross.

Capt. WILLIAM JAMES DOWLING, M.C., attd. 3rd Bn., M.G. Corps, T. attd. 142nd Fd. Amb.—He was in charge of stretcher-bearers during very heavy fighting lasting for two days, and repeatedly went forward to satisfy himself that the R.A.P. were being kept clear. On many occasions he himself led forward stretcher squads under very heavy fire. He invariably displayed great gallantry, and afforded a magnificent example to all ranks working under him.

Capt. (acting Major) JOHN CREIL ALEXANDER DOWSE, M.C., attd. H.Q., 63rd Div.—For conspicuous gallantry and devotion to duty. This officer controlled the evacuation of wounded from the whole of the divisional front under artillery, machine-gun, and rifle fire, and their rapid and efficient evacuation was due to his untiring zeal and energy in maintaining constant communications between battalions and field ambulances. He set a splendid example to all ranks.

Capt. HUGH HART, M.C., No. 5 Fd. Amb., Can. A.M.C.—During an action this officer was in charge of the field ambulance stretcher-bearers. His work under very heavy machine-gun and shell fire was characterised by thoroughness and a clear and concise idea of the situation at all times which was due to his keeping in close touch with the rapidly advancing infantry. On this and other occasions he cleared all casualties with exceptional rapidity. His courage and tireless persistence were a source of inspiration to all under him.

Lieut. WILLIAM PEAT HOGG, M.C., I.M.S.—For conspicuous gallantry and devotion to duty. When his aid-post was heavily shelled he collected all his casualties with great coolness and promptitude, and conducted them to a new post. He has previously done similar fine work in action.

Capt. JOSEPH REGIS ALBERT MARIN, M.C., Can. A.M.C., attd. 22nd Bn., Can. Inf., Quebec R.—During three days' hard fighting he was indefatigable in his attention to the wounded, working often under heavy fire. He saved many lives by his skill and devotion to duty. When all the officers had become casualties, and he himself was wounded, he remained at duty and continued his good work. Later on he was severely gassed and had to be evacuated. The example of his self-sacrificing and gallant conduct had a great effect on the whole battalion.

Temp. Surg. FRANK PEARCE POCOCK, D.S.O., M.C., R.N., attd. Drake Bn., R.N.V.R.—He attended to the wounded under very heavy fire and most adverse circumstances during operations lasting several days. His courage and self-sacrificing devotion to duty were a splendid example to his stretcher-bearers, and his skill was instrumental in saving the lives of many wounded men.

Temp. Capt. (acting Major) MAURICE ALOYSIUS POWER, M.C., attd. 148th Fd. Amb.—For conspicuous gallantry and devotion to duty. Whilst in charge of stretcher-bearers he attended to and collected wounded under heavy machine-gun fire. He worked unceasingly directing stretcher-bearers, and evacuated several hundred wounded from the R.A.P.'s in his sector. Although wounded (for the third time) he remained on duty and showed great endurance, as on previous occasions.

Capt. (acting Major) CUTHBERT SCALES, M.C., attd. 150th Fd. Amb.—For conspicuous gallantry and devotion to duty when in charge of stretcher-bearers. He exposed himself continually, moving from place to place to collect the wounded under heavy machine-gun and rifle fire. Thanks to the close touch he kept with the battalions, several hundred wounded were quickly collected and evacuated.

Capt. (acting Major) HERBERT WILLIAM WADGE, M.C., No. 10 Fd. Amb., Can. A.M.C.—This officer was in charge of the stretcher-bearers of the ambulance during five days' fighting. He worked continuously, directing the evacuation of the wounded in the forward area. Under his leadership the bearers worked strenuously, and the wounded were evacuated with great rapidity. Although considerably shaken by the explosion of a shell, he continued his work.

Capt. THOMAS WALKER, M.C., attd. 23rd Lond. Fd. Amb.—For conspicuous gallantry and devotion to duty. He took a motor ambulance car to an advanced regimental aid-post under very heavy shell fire and evacuated the wounded. Throughout the whole action he displayed great skill and disregard of danger in handling his bearers, and was night and day in the line, keeping touch with the regiments, under heavy shell fire.

Temp. Capt. PHILIP HEWER WELLS, M.C., attd. 2nd Bn., C. Gds.—When moving up to an aid-post with the battalion headquarters a shell fell on the party, causing many casualties, including the only other officer. Capt. Wells, showing complete disregard for personal safety, organised the party and attended to the wounded. Throughout the day he ceaselessly carried on his duties, and under most trying conditions, being exposed to heavy shell-fire the whole time. In spite of the number of wounded he managed to attend to all and arrange for their evacuation.

The Military Cross.

Capt. SIDNEY GEORGE BALDWIN, No. 9 Fd. Amb., Can. A.M.C.—For conspicuous gallantry and devotion to duty. Under his direction the wounded were dressed and removed from the battlefield without any delay. He often led his bearers through machine-gun fire to reach wounded men, whom he successfully evacuated. All through the fighting he displayed great disregard of danger.

Lieut. BAWA HARRISHAN SINGH, I.M.S.—For conspicuous gallantry and devotion to duty and coolness under fire when in charge of the dressing station of the ambulance. The dressing station came under heavy fire at night and the situation was critical for a time. He, however, collected the wounded and brought them in. He also showed great coolness and initiative when the ambulance was bombed by aeroplanes during and after the attack.

Temp. Surg. DAVID LEISHMAN BAXTER, R.N., attd. 1st Bn., R. Marines.—For conspicuous gallantry and devotion to duty during an attack. He early established an aid-post well forward, and continued to move forward with the advance, showing utter disregard of personal danger when searching for wounded and having them dressed under heavy fire. He caused all wounded to be rapidly evacuated, and throughout set a very fine example to his staff.

Capt. NEIL DOUGLAS BLACK, Can. A.M.C., attd. 25th Bn., Can. Inf., Nova Scotia R.—For conspicuous gallantry and devotion to duty. With absolute indifference to the heavy shell fire this officer advanced with the leading companies and attended to the wounded. The second afternoon of the attack he advanced beyond the line under intense enemy machine-gun fire and dressed the wounded of other battalions. His coolness and example were a source of inspiration to officers and men.

Capt. TILLMAN ALFRED BRIGGS, Can. A.M.C., attd. 116th Bn., Can. Inf., 2nd C. Ont. R.—During an attack he rendered invaluable assistance to the wounded of this and other battalions. He attended to a number of casualties in the jumping-off position in spite of heavy machine-gun and artillery barrage. Most of his dressers became casualties, but he continued to dress the wounded. As soon as he had attended to those he pushed forward across the open and assisted those who had fallen. His services were most valuable, and his work of a very high order. He displayed remarkable coolness and energy under fire.

Capt. HERMAN MACLEAN CAMERON, No. 3 Fd. Amb., Can. A.M.C.—For conspicuous gallantry and devotion to duty. This officer performed valuable work in establishing a new A.D.S. to conform with the advancing line, under heavy machine-gun fire and artillery barrage, working continuously for 24 hours without rest.

Temp. Capt. FREDERICK ORLANDO CLARKE, attd. 149th Fd. Amb.—For conspicuous gallantry and devotion to duty in attending to and evacuating the wounded from the forward area under heavy rifle and machine-gun fire. He worked on until every case had been evacuated, and set a splendid example of zeal and endurance to all ranks under him.

Temp. Capt. ANDREW LESLIE EDMUND FILMER COLEMAN, attd. 2nd Bn., S. Gds.—For conspicuous gallantry, tireless energy and devotion in tending the wounded during operations. For two days and nights he never left his post, though subjected to continuous machine-gun fire and frequent bombardments of high explosives and gas. During this period a continuous stream of wounded poured in, both from his own and other units, and by his prompt attention and ceaseless hard work he undoubtedly saved the lives of many severely wounded cases.

Capt. (acting Major) FRANK COLEMAN, 6th Lond. Fd. Amb.—He displayed conspicuous gallantry and devotion to duty at an advanced dressing station which was frequently under heavy shell fire and night bombing. He attended to and arranged for the evacuation of a very large number of wounded, and his skill and able organisation were the means of saving several lives.

Temp. Capt. PURSER DAVIES, attd. 6th (London) Fd. Amb.—He worked with little or no rest for 60 hours in the open under heavy fire, dressing and evacuating the wounded. His conspicuous example of gallantry and self-sacrificing devotion to duty were an inspiration to the stretcher-bearers, whose services he organised with great ability. He saved many lives by his skill.

Temp. Capt. TREVOR G. FEATHERSTONEHAUGH.—For conspicuous gallantry and devotion to duty in attending to the wounded and withdrawing them to cover. In doing so he had constantly to move across ground exposed to fire. It was due to his ability and coolness that casualties were evacuated so expeditiously, thus preventing any hampering of the critical operation in progress at the time.

Temp. Capt. JOHN FINNEGAN, attd. 7th Bn., Lincolnshire R.—For conspicuous gallantry and devotion to duty. At one time, when the battalion was held up lining a bank, he continued to move up and down what was actually the front line, under enfilade fire, attending to and evacuating wounded of his own battalion and also of other divisions. By his disregard of danger for himself he saved numerous lives of others.

Capt. DAVID DAWSON FREEZE, Can. A.M.C., attd. R. Can. R.—In an attack he displayed great courage in dressing wounded under heavy shell and machine-gun fire. He followed close up with the battalion in the attack and, in the most exposed position, he continued to dress the wounded and organise carrying parties, so that all the battalion casualties were evacuated in very short time. After the objective had been reached he proceeded in advance under heavy machine-gun fire, and dressed the wounds of a large number of the enemy and evacuated them. Learning that a number of men of another division were lying in front of our line, having been wounded two days previously, he proceeded under heavy fire, dressed their wounds and supervised their evacuation. His devotion to duty throughout was admirable.

Temp. Capt. DOUGLAS HUGH AIRD GALBRAITH.—For conspicuous gallantry and devotion to duty. He was wounded in the head whilst attending to a wounded officer, and, though in great pain, continued to carry out his duties for the remainder of the day with zeal and determination.

Capt. ARTHUR HINES, Can. A.M.C., attd. 26th Bn., N. Brunswick R.—For conspicuous gallantry and devotion to duty during an attack. He went forward with the attacking waves, and on numerous occasions, in the open and in face of the heaviest shell and machine-gun fire, dressed the wounded. His utter disregard of danger was a constant source of inspiration to all ranks.

Temp. Capt. EDWIN LANCELOT HOPKINS.—For conspicuous gallantry and devotion to duty in dressing wounded under fire during a reconnaissance. He has on all occasions displayed great coolness and resource in carrying out his work.

Capt. JAMES STEWART HUDSON, Can. A.M.C., attd. 1st Bn., Can. Mtd. Rif.—For conspicuous gallantry and devotion to duty during operations. He attended to the wounded under exceptionally heavy shell and machine-gun fire. He personally superintended the collection of wounded, and organised stretcher parties. His coolness and courageous conduct set a high example to all.

Capt. ROY BERTRAM JENKINS, Can. A.M.C., attd. 24th Bn., Can. Inf., Quebec R.—For conspicuous gallantry and devotion to duty. During two days' fighting this officer accompanied the troops, and was tireless in attending to the wounded under heavy shell, gas, and machine-gun fire. As soon as the battalion had made good its line he established a rear aid-post close up, where he received and evacuated wounded. Being exposed to fire himself, he arranged what cover was possible for the wounded and continued at work until he was sure that all had been cleared. He worked unceasingly, never thinking of himself.

Capt. ALEXANDER JOHNSTONE.—For conspicuous gallantry and devotion to duty. He displayed the utmost energy and coolness in collecting, dressing, and evacuating the wounded under heavy fire. Through his untiring efforts 200 cases were disposed of in a very short time.

Temp. Capt. JAMES GAYMER JONES.—For conspicuous gallantry and devotion to duty. Although exposed to heavy and continuous shell fire throughout the day, he continued to dress the wounded in the gun line, thereby alleviating much suffering and saving many lives. His courage on all occasions has been most marked.

Temp. Lieut. RATENSHAW NARIMAN KAPADIA, I.M.S.—For conspicuous gallantry and devotion to duty. Exposed to heavy fire, he continued throughout the action to collect and dress the wounded, who were much scattered, thereby saving many lives.

Temp. Surg. CHARLES EDWARD LEAK, R.N., attd. Hawke Bn., R.N.D., R.N.V.R.—He was with the battalion during six days' incessant fighting, and displayed untiring devotion to duty, dressing the wounded under constant fire. His gallantry and coolness were a splendid example, and inspired the stretcher-bearers under his command to great efforts to evacuate all the wounded, which was accomplished with admirable care.

Temp. Lieut. DOUGLAS BURROWES LEITCH, attd. 13th Bn., Welsh R.—For conspicuous gallantry and devotion to duty. When his battalion came under heavy shell and machine-gun fire he went forward and rendered first aid to men lying in the open and removed them to cover, being shot at by snipers and machine guns while doing so. His zeal and disregard of danger throughout the operations were splendid. Finally he was severely wounded.

Temp. Capt. JOSEPH PATRICK MCGREHIN, attd. 4th Bn., R. Fus.—While proceeding to assembly positions he was knocked over by a large piece of shell and badly shaken. Nevertheless he pushed on and established his O.P. behind a bank. Unfortunately, unknown to him, it was in the vicinity of a water point, and was very accurately shelled all day and finally hit. In spite of this, he worked on with the greatest courage, dressing with care all the wounded, and in one case amputating a foot.

Capt. ROBERT DEWAR MACKENZIE, Can. A.M.C., attd. 15th Bn., Can. Infy., 1st C., Ontario R.—For conspicuous gallantry and devotion to duty. He dressed wounded under continuous shell fire, and kept moving his dressing station forward, so as to be able to attend to the more serious cases. He cleared the cases with the utmost dispatch, and many times during the day went up, under shell and machine-gun fire, to dress stretcher cases. His conduct throughout was deserving of high praise.

Capt. DONALD CAMPBELL MALCOLM, 8th Fd. Amb., Can. A.M.C.—He was in charge of the bearer division in the left sector during the fighting. He showed great initiative and judgment at all times, keeping in close touch with the advancing troops and clearing the wounded. He worked continuously for 48 hours searching for and attending the wounded in the open. On one occasion when the advance was delayed near a wood he led his stretcher squads across the open ground which was being swept by machine-gun fire and brought many wounded back to safety. He displayed the greatest coolness under fire and a perfect disregard for personal safety during the entire action.

Capt. JOSEPH REGIS ALBERIC MARIN, Can. A.M.C., attd. 22nd Bn., Quebec R.—For conspicuous gallantry and devotion to duty during an attack. He, through his prompt dressing of wounds under heavy shell and machine-gun fire, alleviated the sufferings of many wounded and saved the lives of some of the more seriously wounded. His fearless example had the best possible effect on the moral of the men. He worked with determination and cheerfulness for two days under very trying and dangerous conditions.

Temp. Capt. WILLIAM MILLERICK, attd. 10th Bn., A. & S. Highrs.—For conspicuous gallantry and devotion to duty. Hearing that there were a number of severely wounded cases in a village, which could not be moved until properly dressed, this officer at once went forward and carried out his duties under heavy fire of every description. He continued his work untiringly throughout the day, and by his skilful organisation of dressing and carrying parties was undoubtedly responsible for saving many lives.

Temp. Capt. FREDERICK HAROLD MORAN, attd. 15th Bde., R.F.A.—For conspicuous gallantry and devotion to duty during an advance. Throughout the operations he maintained his aid-post practically at the battery positions, and dressed wounded of many units under heavy shell fire. He more than once passed through heavy barrage to get at and attend to wounded. His zeal and disregard of personal safety were splendid.

Temp. Capt. (acting Major) DUNCAN METCALFE MORISON, 38th Fd. Amb.—When the infantry were ordered to attack at short notice he went forward through a heavy barrage and completed the necessary arrangements with the medical officer of the battalion for the evacuation of the wounded. His gallantry and devotion to duty ensured the wounded being rapidly cleared and many lives were saved thereby.

Capt. DUNCAN ARNOLD MORRISON, 1st Fd. Amb., Can. A.M.C.—For conspicuous gallantry and devotion to duty. He accompanied the advancing infantry to the final objective, and though wounded himself remained on duty, continuing to do excellent work during two days' operations, establishing an A.D.S. as soon as the infantry passed through. He behaved splendidly.

Capt. ROBERT DAVIES MOYLE, 2nd Fd. Amb., Can. A.M.C.—For conspicuous courage and devotion to duty. He followed the infantry into the open while it was still under machine-gun fire. Owing to the condition of the ground it was impossible to get transport up, but he organised bearer parties, collected all wounded into a place of safety, and succeeded in securing dressings, food, and water for them, saving many lives. He set an example to all ranks under him.

Lieut. (temp. Capt.) WILLIAM DOUGLAS NEWLAND, 92nd Fd. Amb.—Under conditions of open warfare he collected a number of wounded for evacuation. The place came under very heavy shell fire, due to a number of Tanks passing close to his post. With great courage and devotion he remained with the wounded until he was able to clear them all, although the fire was so heavy that all troops had to leave the immediate neighbourhood.

Capt. FREDERICK MCGREGOR PETRIE, Can. A.M.C., attd. 31st Bn., Alberta R.—This officer displayed great courage, coolness, and devotion to duty under heavy fire and in most trying conditions. He showed great executive ability in the evacuation of wounded, and, although the casualties were very heavy, at no time was there any congestion at the R.A.P. By his skilful organisation and untiring energy many wounded were evacuated during the operation.

Temp. Lieut. GEORGE FITZPATRICK RIGDEN, attd. 16th Bn., Lan. Fus.—He established a first-aid post well forward, and in spite of heavy machine-gun fire carried on his duties with admirable self-possession, several times going forward in face of intense fire to dress wounded lying in exposed positions. It was largely due to his unselfish devotion that some of the most serious cases received prompt attention. His courage throughout was most marked. Finally he was wounded.

Capt. LEWIS WILSON SHELLY, attd. No. 1 Aeroplane Supp. Depot, R.N.—For conspicuous gallantry and devotion to duty. When this depot was heavily bombed in a night raid he organised a dressing station at the Repair Park, attending the wounded in the open. Several bombs fell close to him, wounding those around him, but he stuck to his work and saved the lives of many by his coolness and courage.

Capt. CHARLES GORDON STRACHAN.—For conspicuous gallantry and devotion to duty in charge of stretcher-bearers. He worked for 24 consecutive hours across open ground which was constantly shelled. He rallied his bearers when somewhat exhausted and disorganised by heavy fire, and set them a very fine example of cheerfulness and complete disregard of personal danger. The successful evacuation of all wounded was largely due to his personal conduct.

Capt. ROY HINDLEY THOMAS, 1st Fd. Amb., Can. A.M.C.—For superintending the evacuation of wounded when he went over the entire area, still under heavy fire, locating the wounded, and after dark succeeding in safely removing them all. His untiring devotion to duty, initiative in establishing collecting-posts, and organisation of carrying parties undoubtedly saved many lives.

BROUGHT TO NOTICE.

The names of the following medical officers, all of the R.A.M.C., have been brought to the notice of the Secretary of State for War for devotion to duty and valuable services rendered by them when prisoners of war, during epidemics of cholera and typhus fever, at the Prisoners of War Camp at Wittenberg, Germany:—

Capt. S. Field (since deceased); Maj. W. B. Fry (since deceased); Lt. (temp. Capt., acting Major) J. La F. Lauder, D.S.O., M.C.; Maj. H. E. Priestley, C.M.G.; Capt. A. A. Sutcliffe (since deceased); Maj. A. C. Vidal, D.S.O.

Also the following for valuable and distinguished services rendered in connexion with the operations in North Russia:—

Lt. F. Evans, R.A.M.C. (T.F.); Lt.-Col. T. McDermott, R.A.M.C.

FOREIGN DECORATIONS.

French.

Croix de Guerre.—Col. G. W. Barber, C.M.G., D.S.O., Austr. A.M.C.; Maj. H. d'A. Blumberg, R.A.M.C. (T.F.); Bt.-Maj. L. G. Bourdillon, D.S.O., M.C., R.A.M.C.; Capt. E. J. Dickinson, M.C., Can. A.M.C.; Temp. Capt. (acting Maj.) D. McKelvey, M.C., R.A.M.C.; Capt. G. W. Rogers, M.C., R.A.M.C. (T.F.); Temp. Capt. (acting Maj.) H. B. G. Russell, R.A.M.C.; Capt. (acting Lt.-Col.) G. P. Taylor, D.S.O., M.C., R.A.M.C.; Capt. (acting Maj.) A. P. Thomson, M.C., R.A.M.C. (T.F.); Maj. F. L. Wall, M.C., Austr. A.M.C.

Croix de Guerre, avec Palme.—Col. R. J. Blackham, C.M.G., C.I.E., D.S.O., A.M.S.

Sir Nestor Tirard has returned to 74, Harley-street, W.1, on his retirement from the command of the Fourth London General Hospital, Denmark-hill.

THE IRISH DISPENSARY DOCTORS' AGITATION.—The fight between the boards of guardians and their dispensary medical officers has taken an entire change owing to a resolution, passed unanimously by the Cookstown (Co. Tyrone) board of guardians on Jan. 11th, condemning the present dispensary system as being unsatisfactory both to the ratepayers and to the poor, and stating that the time had arrived when the poor man should have choice of a doctor for himself and his family. The idea underlying this motion (a copy of which it was decided to send to the Tyrone M.P.'s, to the Irish Chief Secretary, and to each Poor-law board in Ireland) is that the dispensary "lines" should be made available to any medical practitioner who was willing to accept them, and who would be paid at each quarter for the number of the "lines" that had been presented to him. It will be interesting to note what other boards of guardians will do in the matter. At the Coleraine board of guardians on Jan. 18th letters were read from all the dispensary doctors in that union, returning the increase of salary for the quarter, on the ground that the scale fixed by the guardians was wholly inadequate to meet the requirements of the doctors. It was moved and seconded by two of the guardians to take no further action in the matter, but saner advice was followed, and an amendment was carried (14 to 8) to consider the question at a special meeting, the proposer of the amendment saying that the scale that they had adopted was inadequate, and that the doctors should be paid a decent salary. So the question rests for the present.

URBAN VITAL STATISTICS.

(Week ended Jan. 18th, 1919.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at 16,500,000 persons, the annual rate of mortality was 15.5, against 16.1 and 16.0 per 1000 in the two preceding weeks. In London, with a population slightly exceeding 4,000,000 persons, the annual death-rate was 14.8, or 1.0 per 1000 below that recorded in the previous week; among the remaining towns the rates ranged from 3.8 in Gloucester, 4.5 in Smethwick, and 5.9 in Gillingham, to 23.5 in West Hartlepool, 26.0 in Liverpool, and 26.5 in Bootle. The principal epidemic diseases caused 161 deaths, which corresponded to an annual rate of 0.5 per 1000, and included 60 from diphtheria, 49 from infantile diarrhoea, 24 from whooping-cough, 15 from scarlet fever, 8 from measles, and 5 from enteric fever. The deaths from influenza, which had steadily declined from 7559 to 380 in the ten preceding weeks, further fell to 274, and included 43 in London, 33 in Liverpool, 18 in Manchester, and 12 in Sheffield. There were 5 cases of small-pox, 1032 of scarlet fever, and 1145 of diphtheria under treatment in the Metropolitan Asylums Board Hospitals and the London Fever Hospital, against 5, 1058, and 1139 respectively at the end of the previous week. The causes of 54 deaths in the 96 towns were uncertified, of which 10 were registered in Birmingham, 9 in Liverpool, 5 in Gateshead, and 4 in Manchester.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2,500,000 persons, the annual rate of mortality was 17.0, against rates increasing from 14.8 to 18.6 per 1000 in the four preceding weeks. The 319 deaths in Glasgow corresponded to an annual rate of 14.9 per 1000, and included 6 from whooping-cough, 4 from diphtheria, 2 from infantile diarrhoea, and 1 from scarlet fever. The 135 deaths in Edinburgh were equal to a rate of 21.1 per 1000, and included 8 from whooping-cough and 4 from diphtheria.

Irish Towns.—The 172 deaths in Dublin corresponded to an annual rate of 22.1, or 0.9 per 1000 above that recorded in the previous week, and included 3 from infantile diarrhoea and 1 from measles. The 121 deaths in Belfast were equal to an annual rate of 15.7 per 1000, and included 5 from infantile diarrhoea and 1 from measles.

VITAL STATISTICS OF LONDON DURING DECEMBER, 1918.

In the accompanying table will be found summarised statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or the other of the ten diseases specified in the table was equal to an annual rate of 4.2 per 1000 of the population, estimated at 4,026,901 persons; in the three preceding months the rates had been 4.7, 5.9, and 4.0 per 1000. Among the metropolitan boroughs the lowest rates from these notified diseases were recorded in Chelsea, the City of Westminster, St. Marylebone, Hampstead, Finsbury, and the City of London; and the highest in Fulham, Hackney, Bethnal Green, Stepney, Southwark, and Bermondsey. One case of small-pox was notified during the month; this case belonged to Holborn. The prevalence of scarlet fever was slightly less than in the preceding month; this disease was

proportionately most prevalent in Fulham, Bethnal Green, Stepney, Poplar, Southwark, and Lambeth. The Metropolitan Asylums Board Hospitals contained 1087 scarlet fever patients at the end of the month, against 931, 1184, and 1107 at the end of the three preceding months; the weekly admissions averaged 136, against 164, 178, and 146 in the three preceding months. The prevalence of diphtheria was about 10 per cent. higher than in November; the greatest prevalence of this disease was recorded in St. Pancras, Hackney, Bethnal Green, Southwark, Bermondsey, and Camberwell. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1051, 1155, and 1000 at the end of the three preceding months, numbered 1089 at the end of December; the weekly admissions averaged 146, against 166, 169, and 129 in the three preceding months. The prevalence of enteric fever was about equal to that in the previous month; of the 15 cases notified 3 belonged to Kensington, 2 to Hampstead, and 2 to Lambeth. There were 23 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 43, 56, and 33 at the end of the three preceding months; the weekly admissions averaged 1, against 6, 9, and 3 in the three preceding months. Erysipelas was proportionately most prevalent in Chelsea, St. Pancras, Stepney, Southwark, Camberwell, and Deptford. One case of puerperal fever was notified during the month from each of the boroughs of St. Pancras, Islington, Shoreditch, Battersea, and Wandsworth. Of the 7 cases of cerebro-spinal meningitis 2 belonged to Hammersmith, and 1 each to Paddington, Lambeth, Battersea, Deptford, and Greenwich; while 1 case of poliomyelitis belonged to Holborn and 1 to Poplar.

The mortality statistics in the table relate to the deaths of civilians belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased had previously resided. During the four weeks ended Dec. 28th the deaths of 5717 London residents were registered, equal to an annual rate of 18.5 per 1000; in the three preceding months the rates had been 11.4, 27.3, and 42.3 per 1000. The death-rates ranged from 10.0 in Lewisham, 11.7 in Woolwich, 13.6 in Hampstead, 15.0 in Finsbury, 15.2 in Wandsworth, 16.2 in Hackney, and 16.3 in Greenwich, to 22.0 in Kensington, 22.1 in St. Marylebone, 23.3 in Holborn, 23.8 in the City of Westminster, 25.8 in Southwark, and 26.7 in the City of London. The 5717 deaths from all causes included 124 which were referred to the principal infectious diseases; of these, 13 resulted from measles, 9 from scarlet fever, 36 from diphtheria, 7 from whooping-cough, 5 from enteric fever, and 54 from diarrhoea and enteritis among children under 2 years of age. No death from any of these diseases was recorded during the month in Finsbury, and in the City of London. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in Hammersmith, the City of Westminster, Shoreditch, Greenwich, and Woolwich; and the highest death-rates in Paddington, Holborn, and Southwark. The 13 deaths from measles were 85 below the average number in the corresponding period of the five preceding years, and included 2 in Islington and 2 in Woolwich. The 5 fatal cases of scarlet fever showed a decline of 9 from the average number; 2 of these belonged to Hampstead. The 36 deaths attributed to diphtheria were 25 below the average, and included 6 in Southwark and 3 each in Paddington, St. Pancras, Islington, Hackney, and Bermondsey.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING DECEMBER, 1918.

(Specially compiled for THE LANCET.)

| CITIES AND BOROUGH. | Estimated civil population, 1917. | Notified Cases of Infectious Disease. | | | | | | | | | | Deaths from Principal Infectious Diseases. | | | | | | | | | | Deaths from all causes. | Death-rate per 1000 living. | |

* Including membranous croup.

The deaths from whooping-cough numbered 7, and were 45 below the average; of these, 2 belonged to Holborn. The 5 fatal cases of enteric fever were 3 below the average. The 54 deaths from diarrhoea and enteritis among children under 2 years of age were 38 below the average, and included 6 in Stepney, 6 in Lambeth, 5 in Wandsworth, 4 in Islington, and 4 in Camberwell. In conclusion, it may be stated that the aggregate mortality from these principal infectious diseases in London during December was 62 per cent. below the average.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY, Jan. 30th.—Papers:—Prof. J. C. McLennan and Mr. R. J. Lang: An Investigation of Extreme Ultra-violet Spectra with a Vacuum Grating Spectrograph.—Prof. J. C. McLennan and Mr. J. F. T. Young: On the Absorption Spectra and the Ionisation Potentials of Calcium, Strontium and Barium.—Prof. J. O. McLennan, Mr. D. S. Ainslie, and Mr. D. S. Fuller: Vacuum Arc Spectra of various Elements in the Extreme Ultra-violet.—Mr. R. O. Dearn: Emission and Absorption in the Infra-red Spectra of Mercury, Zinc, and Cadmium (communicated by Prof. J. C. McLennan).—Mr. E. Wilson: The Measurement of Magnetic Susceptibilities of Low Order (communicated by Prof. J. W. Nicholson).—Dr. F. Horton and Ann C. Davies: An Experimental Determination of the Ionisation Potential for Electrons in Helium (communicated by Mr. O. T. R. Wilson).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W. 1.
MEETINGS OF SECTIONS.

Monday, Jan. 27th.
ODONTOLOGY (Hon. Secretaries—F. N. Doubleday, G. Paton Pollitt, J. Howard Mummery): at 7.30 P.M.

Paper:
Captain William Billington, M.S., D.R.C.S., R.A.M.C., Mr. Arthur H. Parrott, M.D.S., L.D.S., and Mr. Harold Round, M.D.S., L.D.S.: Bone Grafting in Gunshot Fractures of the Jaw.

Tuesday, Jan. 28th.
MEDICINE (Hon. Secretaries—Charles R. Box, W. Cecil Bosanquet): at 5.30 P.M.

Papers:
Dr. Gordon Ward: Apyrexial Symptoms in Malaria.
Dr. David Thomson: The Complement Deviation Test in Malaria.

Thursday, Jan. 30th.
BALNEOLOGY AND CLIMATOLOGY (Hon. Secretaries—Olas. W. Buckley, J. Campbell McClure): at 5.30 P.M.

Paper:
Dr. C. F. Sonntag: Temperature Environment and Thermal Debility, a Study of the Beneficial and Injurious Effects of Heat.

The Royal Society of Medicine keeps open house for R.A.M.C. men and M.O.'s of the Dominions and Allies. The principal hospitals in the metropolis admit medical officers to their operations, lectures, &c. Particulars on application to the Secretary at 1, Wimpole-street, London, W. 1.

MEDICAL SOCIETY OF LONDON, 11, Chandos-st., Cavendish-sq., W.
MONDAY, Jan. 27th.—8.30 P.M., Discussion on the Modern Treatment of Gonorrhoea of the Genito-Urinary Organs. Introduced by Col. L. W. Harrison, R.A.M.C. Followed by Capt. D. Thomson, Lieut.-Col. R. Bolam, Major A. Campbell, Capt. D. Lees, D.S.O., Capt. D. Watson, Mr. C. Williams, and others. Medical officers of the Colonial and Allied Armies will be welcomed at the meeting.

TUBERCULOSIS SOCIETY, at the Royal Society of Medicine, 1, Wimpole-street, W.
MONDAY, Jan. 27th.—8.30 P.M., Address:—Dr. J. D. Grant: Practical Remarks on Tuberculosis in Relation to the Upper Air- and Food-passages.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.
WEDNESDAY, Jan. 29th.—4.30 P.M., Paper:—Dr. F. Keeble, C.B.E.: Food Production by Intensive Cultivation.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.
ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

Six Hunterian Lectures on Phases in the Life and Work of John Hunter. The Lectures will be illustrated by Hunterian Preparations, Drawings, and Records:—

MONDAY, Jan. 27th.—5 P.M., Lecture IV:—Prof. A. Keith: John Hunter as a Physiological Anatomist.

WEDNESDAY—5 P.M., Lecture V:—Prof. A. Keith: John Hunter as an Experimental Physiologist.

FRIDAY—5 P.M., Lecture VI:—Prof. A. Keith: John Hunter as an Anthropologist.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON), at the Lecture Theatre of the Medical School, King's College Hospital, Denmark Hill, S.E.

Course of Four Lectures on Malaria. Microscopic specimens and lantern slides will be shown at the two last lectures.

FRIDAY, Jan. 31st.—12 noon, Lecture I:—Col. Sir Ronald Ross, K.C.B., K.O.M.G., F.R.S. Officers and Men of the Royal Army Medical Corps are invited to attend.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

Clinics each week-day at 2 P.M., Wednesday, Friday and Saturday also at 10 A.M.

(Details of Post-Graduate Course were given in issue of Nov. 30th, 1918.)

ROYAL INSTITUTE OF PUBLIC HEALTH, in the Lecture Hall of the Institute, 37, Russell-square, W.C.

Course of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—

WEDNESDAY, Jan. 29th.—4 P.M., Capt. T. Carnwath, D.S.O.: Lessons of the Influenza Epidemic.

Appointments.

FINZI, N. S., M.B., has been appointed Medical Officer in charge of the X Ray Department, St. Bartholomew's Hospital.

Vacancies.

For further information refer to the advertisement columns.

Albion Infirmary.—H.S. £150.
Bath Royal United Hospital.—H.P. and H.S. £150.
Bedford County Hospital.—Res. M.O. £150.
Birkenhead Borough Hospital.—Jun. H.S. £170.
Birmingham General Hospital.—Vacancies on Res. Staff.
Bradford Royal Eye and Ear Hospital.—Ophth. S.
Cardiff City.—Female Asst. M.O. £350.
Devonport Royal Albert Hospital.—Res. H.S. £200.
Dorset County Council.—Temp. Asst. M.O.H. £400.
Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—Female Temp. Asst. S.
Govan District Asylum, Cardonald, Glasgow.—Sen. Asst. M.O. Also Jun. Asst.
Hospital for Consumption and Diseases of the Chest, Brompton.—H.P. 30 guineas.
Italian Hospital.—H.S. £150.
Leeds General Infirmary.—Res. S.O. £150. Res. Aural O. £150. Oph. H.S. £50. Also Two H.S. and two H.P.
Manchester Royal Eye Hospital.—Junior H.S. £120.
Norwich, Norfolk and Norwich Hospital.—Fourth Res. Surg. O. £200.
Putney Hospital, Lower Common, S.W.—Res. M.O. £150.
Queen's Hospital for Children, Hackney-road, E.—Res. M.O. £200. Also H.P. and H.S. £100.
Reading, Royal Berkshire Hospital.—H.P. and Sec. H.S. £250.
Royal Hospital for Diseases of the Chest, 51, City-road, E.C.—Clin. Asst. Royal National Orthopaedic Hospital.—Res. H.S. £100.
South London Hospital for Women.—Female Asst. Path. £150.
Taunton, Taunton and Somerset Hospital.—Sen. H.S. £250.
Tewkesbury Union.—M.O. £55.
University of London.—Examiners.
Western Ophthalmic Hospital, Marylebone-road, N.W.—Vacancies on Medical Staff.
Westmorland Sanatorium, Meathop, Grange-over-Sands.—Sen. Asst. M.O. and Asst. Tuberc. Officer. £350. Also Jun. Asst. M.O. £250.

Births, Marriages, and Deaths.

BIRTHS.

PLATT.—On Jan. 16th, at Daisy Bank-road, Victoria Park, Manchester, the wife of Harry Platt, M.S., F.R.C.S., Captain, R.A.M.C. (F.), of a son.

RANKIN.—On Jan. 11th, at Cairo, Kathleen, the wife of Captain Thomas Thomson Rankin, R.A.M.C., of a son.

TANNER.—On Jan. 12th, 1918, at Nursing Home, Worthing, the wife of Captain W. E. Tanner, R.A.M.C., of a son.

MARRIAGES.

HALLINAN—CROSBIE.—On Jan. 18th, at St. Mary's Church, Clapham, Major William Edward Hallinan, M.C., R.A.M.C., to Lillian Annie Crosbie, daughter of Colonel Crosbie, C.B.

DEATHS.

MOULD.—On Jan. 14th, at his residence, Colwyn Bay, George William Mould, M.R.C.S., in his 84th year.

N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

HEALTH, MEDICINE, AND SANITATION IN INDIA.

II.

Punjab.

THE year 1917 was a healthy one for the Punjab, except for a prevalence of malaria in the last three months. The birth rate, 45.3 per 1000, was 0.1 below the quinquennial average, but the death-rate, 37.9 (the same as in the United Provinces) was 6.7 above the average, and was only exceeded by that for the Bombay Presidency (40.76) in the year under review; the high rate was due entirely to "fevers," which caused 510,812 deaths, equalling 26.42 per 1000, the highest mortality since 1908. Cholera was somewhat prevalent in Sialkot district, where there were 232 deaths from this disease; in Sialkot itself there were 11, and in Multan 118 deaths. Plague caused only 0.5 deaths per 1000, but as 4084 (nearly half) of these occurred during the last two months of the year, a bad epidemic was anticipated in 1918. At Simla there were 25 cases of enteric fever, 22 of which were among Kur peans; in 10 of these cases the disease was considered to have been contracted locally—no definite or common origin could be traced. Colonel H. Hendley, I.M.S., who presents the report, held the appointment of Sanitary Commissioner throughout the year, in addition to that of Inspector-General of Civil Hospitals.

North-West Frontier Province.

In the North-West Frontier Province the birth-rate in 1917 (32.1 per 1000) was 2.2 below the quinquennial average, and was lower than in any other province in India, except Assam; the decline is attributed to the severe outbreak of malaria in 1916. The death-rate was 29.9 per 1000, being higher than the quinquennial average (25.5); nearly all the deaths (viz., 24.8 per 1000) were returned as "fevers." No other disease caused as much as 1.0 per 1000 mortality. Lieutenant-Colonel T. W. Irvine, I.M.S., considers that the general population are too lethargic and lazy to take quinine until the attack actually comes on, and is doubtful whether its unsupervised use is of any use. He recommends the cheaper quinine as of value in treating mild infections.

Bihar and Orissa.

The growing appreciation of Western medicine is noticeable everywhere in the statistics of attendance both of indoor and outdoor patients at the charitable dispensaries. Most district boards have now set before themselves a definite programme for increasing the number of their dispensaries, and at the same time private practitioners are becoming more numerous and enterprising, and Government service is by no means the only career open to successful medical students. The province has now established a board of medical examiners and has adopted a Medical Act to control the regulation of qualified practitioners and penalise fraudulent practitioners. In this province the birth-rate for 1917 was 40.4 per 1000, a considerable increase over the ratio for 1916 (36.6), probably due to stricter registration, but lower than the average for 1911-15, which was 42.8. A table is given showing the great variation in birth-rates in the different provinces of India. Assam stands lowest (in 1917) with 31.3, and the Central Provinces highest with 48.1 per 1000. For the quinquennium, 1911-15, Madras was lowest (31.6), and the Central Provinces highest (49.2). The death-rate in Bihar and Orissa was 35.2, also higher than the ratio (32.8) for 1916, and that for 1911-15 (31.1). This increase is considered by Major W. C. Ross, I.M.S., the Sanitary Commissioner, to be a real increase, due to the general unhealthiness caused by prolonged and excessive rains. The mortality from cholera (3.1) was high. On account of the expense and difficulty in obtaining potassium permanganate for well disinfection, quicklime was used, also chloroform. The mortality from fevers (22.5) was also high, the decennial ratio for 1907-16 having been 20.6 per 1000. Anti-malarial measures on the usual comprehensive lines are being carried out, but the people appear to take small interest in the work, and the difficulty of getting them to take quinine as a preventive continues, though matters appear to be now improving. Plague caused a mortality of 1.3 per 1000, higher than in the preceding year (0.7), due partly to copious and prolonged rains. Inoculation was carried out, but it is stated that it "has never been popular, and as it is not a general preventive measure of any real value, the maintenance of a special staff for inoculation has been discontinued." Rat-killing by public agencies is also considered to be "essentially a failure because it does not accomplish the destruction of any appreciable number of rats." Evacuation appears to be the only preventive of practical value, because it is accepted by the people and is carried out promptly. Major Ross advocates "a slow but definite programme of legislation, involving a gradual advance in the standard of sanitation required in communities, with a view to enforcing the idea of citizenship and responsibility in sanitary matters."

Assam.

From the vital statistics for 1916 it does not appear that the health of the province was seriously affected by the disastrous floods of October. There were cholera epidemics of some severity in Goalpara, Darrang, Nowgong, and North Lakhimpur, but on the whole the mortality from this disease was below the average. There was no change in the general death-rate from small-pox, but the increased efficiency with which the provisions of the Vaccination Act are administered produced a substantial reduction in the prevalence of this disease in urban areas. Fever was rather more severe than usual in all districts. The mortality from kala-azar varied little from that of the preceding two years, but the tendency which this disease is showing to spread in the upper districts of the Assam Valley, which have hitherto been free from it, is a source of considerable anxiety. In Jala the death-rate per 1000, which was reduced from 43.53 in 1914 to 21.40 in 1915, again fell to 18.51 in 1916, the last figure being the lowest ever recorded for the province. The number of hospitals and dispensaries in the provinces rose during the year from 205 to 215, of which 124 were supported by local bodies, 18 by private persons, and 73 by the State.

Owing to the transfer of medical officers to military service and the difficulty of securing qualified substitutes the total number of institu-

tions at work is still less by ten than it was at the commencement of 1914. A Pasteur Institute and School of Research was opened at Shillong in January, 1917, and has made a most promising start. The Assam Medical Bill, the object of which is to protect the medical profession and the public from imperfectly trained and irregularly qualified practitioners, has been passed into law.

The birth-rate in Assam for 1917 was 31.35 per 1000, slightly higher than in 1916 (30.52), but lower than the quinquennial average (1911-15) of 32.75, and lower than in any other province for 1917. The Sanitary Commissioner, Major T. C. McCombie Young, I.M.S., calls attention to the defective character of the registration and of the population returns. The death-rate was 27.09, compared with 28.59 for 1916 and 26.37 for 1911-15. An outbreak of typhoid occurred at Shillong; the civil surgeon, Dr. Gordon Roberts, and Captain R. Knowles, I.M.S., the director of the Pasteur Institute, carried out inoculation of 1760 natives, this being the first instance of an Indian population voluntarily submitting to typhoid vaccine inoculation on a large scale. An outbreak of diphtheria occurred in a boarding school at Shillong, apparently imported from Calcutta; stringent measures of isolation were adopted, suspected cases and contacts were swabbed, and the very large European child population of this crowded hill station saved from an epidemic by the prompt action of the medical authorities. Much work has been done in the way of malaria prophylaxis, especially at Lumding, an important junction on the Assam-Bengal railway. A large distribution of quinine tablets was made, and substantial improvements effected in details of drainage, application of larvicides, &c. Kala-azar, as has been indicated, increased during the year and extended to areas previously unaffected. The disease is "tending to extinction" in Sylhet, but Nowgong, with 591 deaths from this cause, shows a considerable increase over any previous year, and the disease is now endemic in this district.

The United Provinces of Agra and Oudh.

The year was an unhealthy one. There was a heavy death-roll from cholera, plague, and malaria, owing to the long continuation of wet. The death-rate was 39.95 per 1000. The birth-rate in 1917 was 46.03 per 1000, the quinquennial average (1912-16) having been 44.91. Shahjahanpur district had the excessively high death-rate of 79.22, due to cholera and fevers. The excessive mortality throughout the provinces is put down to cholera and fevers, including under the latter head relapsing fever. Infantile mortality was excessive (215.7), tetanus being unusually prevalent. Pamphlets and instructions to mothers and midwives in the vernacular have been distributed, midwives have been trained, and at Benares, Lucknow, and Allahabad municipal dairies have been established. Cholera is still somewhat prevalent (0.46 deaths per 1000) in spite of disinfection of wells and general sanitary improvements, but is much less fatal than had latterly been the case (1.24 deaths per 1000 in 1907-16). Plague caused 129,034 deaths (2.76 per 1000), a large increase over the quinquennial average of 1.85. This is considered to be disquieting, but the weather conditions favoured spread of the disease. The fever death-rate (27.06) was also unsatisfactory, being considerably higher than the quinquennial average of 21.74; in Shahjahanpur district the ratio was 58.69 per 1000. Owing to the scarcity of qualified officers, malarial investigations had unfortunately to be discontinued, but anti-malarial works were carried out, especially at the important station at Meerut. Owing to the high price of quinine the "quininisation" of school children was ordered by the Government to be dropped. Colonel C. Macgregor, O.I.E., the Sanitary Commissioner, considers the high mortality from plague and "fevers" to have been chiefly due to excessive rainfall.

Baluchistan.

The province has enjoyed immunity from every kind of epidemic disease except cholera, which appeared in Zhob in June, 1916, when 35 villages were infected, causing 328 cases and 174 deaths. Thanks to the timely and energetic efforts of the local medical and civil officers the disease was prevented from spreading still further. A party of Poonindas who passed through the district on their way from the Punjab to Afghanistan was responsible for introducing the disease into Zhob. Antimalarial measures were adopted in several places with good results. During the year under report the number of malarial cases treated in the dispensaries of the province fell by 3.77 per cent. as compared with the number treated in the previous year. The vaccine operations among the Zarkun and Mari tribes show that the most ignorant and backward people of Baluchistan are now beginning to appreciate the advantages of vaccination.

Coorg.

An index in the well-being of the labourer is to be found in the state of the public health, which was considerably better than has been noted for several years. The number of births was 9.68 per cent. above, and the number of deaths 24.52 per cent. below the average for the previous five years. Quinine prophylaxis against malaria continued to be administered in the secondary schools with satisfactory results. 50,500 quinine powders were sold to the public through the agency of the post offices.

Delhi.

Sanitary conditions, especially within the city and civil station, continued to show the improvement which has resulted from the attention paid in recent years to this side of administrative activity. The municipal report shows that the sanitary establishment was increased, a new slaughter-house constructed, and drains extended. The important and costly antimalarial measures in the Bela were pushed on and one section completed; in the civil station a brick channel was constructed to the Najafgarh drain cut. Considerable additions were made to the city western extension, which should in the time draw off a large number of malarial occupations from the city. The heavy monsoon rains rendered the year less healthy than its predecessor, but the death-rate (32.92 per 1000) nevertheless compared very favourably with the years preceding 1914. The excess of births over deaths, though lower than in 1915-16, also reflected a far more satisfactory state of things than in 1914.

The Andaman and Nicobar Islands.

The record of the health of the year shows improvement as compared with that of 1915-16, but the incidence of sickness and mortality has still been high. The main cause of sickness was, as usual, malaria, and of death pneumonia, now recognised to be a direct result of malarial infection in the settlement. Malaria not only affects the convict population, but persistently saps the vigour of the entire official staff, leaving after-effects in its wake which are often permanent.

Hyderabad.

The difficulties to which the people were exposed on account of unseasonable rain and high prices were still further aggravated by an extremely severe epidemic of plague. In Hyderabad city alone no less than 14 053 persons died of this disease between the months of October and April. In the districts the epidemic was no less severe, and in out-of-the-way villages the suffering was very great, as it was impossible to render these people any material assistance. The results of this visitation were far-reaching and extended to almost every department of the State. Progress on the more important works was seriously delayed and schools and courts were closed for several months. Numerous temporary hospitals to deal with plague were opened at the capital and in the districts.

Central India.

All the Agencies, except Baghelkhand and Bundelkhand, were visited by plague, the only respite being in the hot weather. The incidence was severest in Indore, where there were 1777 deaths out of 2336 in the province. Fortunately, people now evacuate their houses as soon as rains begin to die, and the increasing popularity of inoculation is shown by over 90 000 persons having been inoculated in Indore. Cholera, in all parts of Central India, accounted for 5474 deaths. Small-pox was prevalent, but reliable figures cannot be given. The birth-rate shows a further fall from 11.81 to 11.15 per 1000, but the statistics are unreliable. The death-rate increased from 9.55 to 10.60 per 1000.

LEMON JUICE OR LIME JUICE?

To the Editor of THE LANCET.

SIR,—Yes, the "lime juice" used by the British Navy in 1854 was lemon juice, as Fleet Surgeon W. E. Home supposes. In my historical inquiry (THE LANCET, Nov. 30th, 1918) I gave the approximate date of the change from lemons to limes as "about 17 years" after, not the return of Sir John Ross in 1843, but the return of Sir James Clarke Ross from his search for Franklin in 1849. Records may be found of the supply of lemon juice from Malta up to the year 1862; this supply was for the whole Navy, excepting only ships on service in the West Indies which, from 1846, were furnished with juice from Bermuda. The Admiralty medical and victualling records later than 1862 are not kept in the Public Record Office, and, since I had enough information for my immediate purpose, I did not pursue further in the records the question of the exact date at which the change was made to West Indian limes. By 1875 the use of West Indian lime juice had been established in the Navy, and the belief in its superiority is further shown by the fact that it was used in the Merchant Service also as far as it was available; about one-third of the merchant ships were supplied with it, the other two-thirds having to be content with lemon juice.

Between these dates—1862, when Malta lemons were still used in the Navy, and 1875, when limes had superseded them—the Merchant Shipping Amendment Act was passed in 1867. Before that, what was supplied to merchant ships as lemon or lime juice was often grossly adulterated, but the mere fact of having so-called "lime juice" on board (compulsory since 1844) was taken by careless-owners and captains as relieving them of any further responsibility for the care of the health of their crews. This Amendment Act of 1867 enacted that the lime or lemon juice issued must be such as had been approved, fortified, and sealed in the presence of an officer of Customs. And juice was received for examination and sealing only from manufacturers who held licences from the Board of Trade. I suppose that it would be on the introduction of these new regulations that the growing West Indian industry would have an opportunity of securing its position, but I have never exactly verified this supposition, and am at present remote from records. In any case, it was certainly about that time.

A fuller account of some facts in the history of "lime juice" is to be published soon in the *Journal of the Royal Army Medical Corps*.—I am, Sir, yours faithfully,
Jan. 21st, 1919. ALICE HENDERSON SMITH.

HEALTH AND RADIANT HEAT.

In his lecture on Coal and National Health, delivered at the Royal Institute of Public Health on Jan. 15th, Professor W. A. Bone admitted that in the past a great deal of coal had been wasted in domestic grates through our ignorance of the first principles of combustion. The science of clothing as well as that of indoor heating and ventilation largely resolved itself, he said, into a question of aiding the skin in maintaining the normal bodily temperature under varying conditions of work and play without symptoms of discomfort and distress. Dr. Leonard Hill had laid down the conditions of comfort and health to be those prevailing in the open on a balmy summer day, with the ground warm to the feet, the surface of the body exposed on the one side to the radiant heat of the sun and on the other to the cooling breeze which played around the head. No monotony, but a continual change of thermal conditions. The cooling and drying breeze round the head meant that more arterial blood had to pass through the vessels supplying these parts in order to maintain the body temperature, and that far more lymph had to pass through the respiratory membranes to maintain the evaporation required to saturate the dry air. Contrast these conditions with the tropical and monotonous state of the warm, humid air of crowded rooms, heated by steam coils, and it became evident both what we ought to aim

at and what we ought to avoid in our domestic heating and ventilation. The British climate being what it is, we should aim at warm floors and avoid monotony in our physical environment by the use of the open fireplace. Much waste of fuel and personal discomfort were, he said, unnecessarily caused by the prevailing practice of flooding living rooms in the early winter mornings with cold, damp air. Living apartments should at all times be sufficiently ventilated and aired whenever the external atmospheric conditions admitted, but in winter-time "airing" should be confined to the middle part of the day. In the early mornings or on cold raw days it was better to keep windows closed and to allow chimneys to draw in the outside air. The immediate line of practical reform lay in the direction of constructing all fireplaces on scientific principles and in substituting for the raw coal a low-temperature "semi-coke" as soon as this could be produced commercially on a large scale at a reasonable price. For gas fires silent combustion and adequate ventilating effect should be insisted upon. The choice between these two types of heating was, he said, determined not so much upon hygienic grounds as on personal predilection and local conditions.

A WARNING.

To the Editor of THE LANCET.

SIR,—Thefts from motor-cars are on the increase. I have just had a nitrous oxide oxygen outfit stolen from my car, which had been left for 25 minutes outside a shop in New Cavendish-street, and I gather from the police that other thefts occurred on the same day, Jan. 15th. As my box weighed about 60 lb., and only contained stuff of value to an anaesthetist, I imagine that the thief is somewhat disappointed. I send this notice in the hope that others in this neighbourhood may be on their guard.

I am, Sir, yours faithfully.

Up, or Wimpole-street, W., Jan. 18th, 1919. H. EDMUND G. BOYLE.

D. R. H.—No English translation of Nagelschmidt's book on Diathermy has appeared, but we are informed that a work on the subject from the pen of Dr. E. P. Cumberbatch, medical officer in charge of the electrical department of St. Bartholomew's Hospital, will shortly be published by Heinemann.

MEDICAL UNANIMITY AND PUBLIC SPIRIT:

THE STATE AND THE DOCTOR.

By SIR HENRY MORRIS, BART., M.A.,

PAST PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND
AND OF THE ROYAL SOCIETY OF MEDICINE OF LONDON.

MY object in publishing the following remarks is to try to induce those who do me the honour to read them to endeavour to promote unanimity between the several sections of the profession with the view to secure (1) satisfactory State and municipal conditions in the National and Municipal Health Service; (2) fuller recognition by the public and the Government of the importance of medical opinion and advice; (3) union of the voices of the profession when legislation is in prospect on questions which gravely concern the mental, physical, and social welfare of the people; and (4) a larger representation of the profession in Parliament and an organised medical party in the House of Commons as a step towards the attainment of these ends.

The systematic fight against disease and the combining of preventive medicine with clinical and curative medicine is becoming yearly more and more a Government function. The medical profession, however, has got to recognise that sanitary matters are among the most important matters of State policy, and that it cannot any longer turn its back on "politics," as hitherto it has always somewhat contemptuously done, but that, on the contrary, so far as medical "politics" go, the profession ought to take quite the leading rôle.

LEGISLATION AFFECTING THE MEDICAL PROFESSION.

Within the last 45 years Parliament has imposed a large number of statutory demands upon the time and service of the medical profession. Under the powers conferred by numerous Acts of Parliament passed since 1871 the general practitioner is liable to be called upon to undertake a great variety of duties concerning and ranging over the whole period of the life of a man, from his cradle to his grave, and extending even beyond to the removal and disposal of his body after death.

The doctors' liabilities under these Acts concern the state of mind and body of men, women, and children, the condition of their property, houses, and tenements, their environment and fitness during school life, their protection against the infinitely small and the abominably loathsome pests which attack their bodies and assault their health, the nuisances about their dwellings, the dangers of their trades and occupations, the workmen's compensation for injuries and their superannuation and pension claims, and a score of other matters, besides the National Insurance Act of 1911, under which 14 millions of persons are eligible for medical care.

And all these Acts of Parliament exacting service from the medical practitioner have been passed by non-medical legislators, some few of the prime movers in which were no doubt prompted and instructed by medical men, but the bulk of whom neither knew nor took the trouble to ascertain the opinion of the general practitioners who are the agents by whom the Acts are mainly made effective.

INADEQUATE REPRESENTATION OF MEDICINE IN PARLIAMENT.

Yet during the whole period of this exploitation of the profession by Parliament the profession has been docile and servile, has done nothing, beyond the British Medical Association, towards becoming an important factor influencing legislation, and remains to this day without any recognised political standing in the State.

As a result of the recent General Election the profession is slightly better in the number of representatives in Parliament than it was before. Out of 37 medical candidates for Parliamentary seats, 16 were successful; but as 5 of the elected are Sinn Féiners, there will, in all probability, be only 11 who will take their seats in the House of Commons, as

No. 4979

against 9 in the last Parliament. Compare these figures with the 92 members of the legal profession (solicitors and barristers) who were elected—67 for England and Wales, 11 for Scotland, 11 for Ireland, 2 for English universities, and one for Trinity College, Dublin. Add to these election results the numerous important well-paid public and political offices which lawyers occupy, and the fact that there are at the present time five ex-Lord Chancellors (one of whom, it is true, is an M.D. of Edinburgh, but he very early in life forsook medicine for law), each in receipt of £5000 a year pension, and a sixth just appointed at the age of 46, with a prospect of long years of a pension after ceasing to receive while in office as Lord Chancellor £10,000 a year—and we get some idea of the comparative advantages and public recognition of the two professions.

MEDICINE AND THE STATE.

This lack of proper State recognition, and of an adequate Parliamentary representation of medicine, is largely due to its self-imposed seclusion from affairs of State, to the reluctance of the profession to take its part in any great national scheme, and its persistent resolve to continue as long as possible as an individualistic class.

This disposition is a legacy from the traditions and prejudices of the priest-physicians of antiquity, and the monastic influences of the Middle Ages; for, notwithstanding the medical treatment of patients in the "Asclepeia"—the ancient Greek equivalent of our modern hospitals—and the efforts of Hippocrates to dissociate medicine from priestcraft and its many superstitious devices, and to break the long-standing and confused connexion between philosophy and medicine, professional individualism has been perpetuated by the devout inculcation throughout the ages of the Hippocratic "Oath" and "Law."

It is to-day, however, becoming apparent to many of the profession, as well as to the public, that the old individualistic character of medical practice is incompatible with modern requirements and must be supplemented by a much wider view of the place which medicine is called upon to occupy in the State; and that in the interest of the community this aloofness of the profession from every movement of a political character can no longer be maintained.

There are two principal reasons for this change of view, one special to the profession, the other a product of the socialistic tendency of democratic administration.

Scientific Development of Medicine.

The first is based upon the constant developments of modern science and the progressive adaptation of scientific discoveries to the practice of medicine and surgery in relation both to diagnosis and treatment.

Whilst this adaptability of many sciences to medical diagnosis and treatment renders necessary a more extended and varied application of medical resources to the Public Health Service it also necessitates the coördination of expert experiences and the coöperation of specialists and general medical practitioners for the efficient up-to-date treatment of private patients.

In the life of a nation, as Karl Marx forcibly pointed out in connexion with the growth of revolutions, the material forces of production at certain stages of development come more and more into conflict with the existing relations of production, or in other words with the relations of private property. In the same way the development of medical and scientific knowledge brings into use improved material means of investigating and treating disease which are incompatible with the old exclusively personal relations between doctor and patient.

As the material forces of industrial production were improved the spinning-wheel, the weaver's handloom, and the private workshop were superseded by the spinning-jenny, the weaver's mechanical loom, and the factory. So in the progress of science the individualism of consulting-room and bedside practice has had to yield to research work in bacteriological and biochemical laboratories, to radiography and other light and electrical processes, and other expert specialities.

As a consequence, the individual services of the family doctor have to a large extent given place to the associated services of a number of medical scientists, and the curative results of treatment in a large proportion of cases are the product of this coöperation—just as the yarn and the fabrics which come from the factories are the outcome of the labour

of many workmen, and not, like the commodities of former times, the single-handed products of individual artisans.

The Medical Profession and the Community.

The second of the reasons for the change of view referred to is the natural democratic doctrine that the community does not exist for the benefit of professions or vocations; that neither do the professions exist for the benefit of individuals only, but that the proper function of each profession is to render such services as are special to it for the benefit of every section of the community and not for those persons only who can afford to obtain them by payment.

The object of professional organisations in a democratic or socialistic State, it is held, ought, in fact, to be to promote the greatest good of the greatest number. This is the spirit of the National Insurance Act, and when wrongly interpreted it is the spirit which exploits the profession for the benefit of the mass of the people without any regard for the dignity and prestige of an ancient, honourable, and learned calling.

RECONSTRUCTION: NATIONAL HEALTH SERVICES.

It follows from the progress of medical science and this conception of the communal services of the professions that there are in prospect, and within the purview of post-war reconstruction, changes, expansions, and, it is to be hoped, improvements in the National Insurance Act, whereby arrangements will be made for bringing modern and highly specialised remedies and means of diagnosis within the reach of the poorer classes, so that the patients of all general practitioners and panel doctors may have the same advantage from improvements in the medical sciences as the rich and well-to-do classes have.

It is to be desired that this will be brought about without interfering with the patient's free choice of doctor, or debarring medical men from attendance on their own patients, or depriving independent general practitioners and consultants of their freedom to render professional services to any persons who desire them, whether those persons are under the National Insurance Act or otherwise.

But it must be realised that a considerable increase in the number of whole- and part-time salaried doctors will be required to cope with the increasing volume of public health work, and that, in view of such increase, steps ought to be taken to make it possible for the ordinary general practitioners to bring their distinctive opinions to bear on the authorities concerning any schemes affecting the National Health Services, as well as to make known their views about the State Clinical Service.

THE TEACHING OF PREVENTIVE MEDICINE.

An outcry is being raised in a certain quarter against the "strange neglect" of teaching preventive medicine and public health in the medical schools of this country, about the necessity of every medical student being as well equipped in all the problems of hygiene as in clinical medicine, and in favour of every medical practitioner being trained to form an integral part of any scheme of preventive medicine in the district in which he practises. To this end a most formidable array of subjects and details of subjects is set forth as necessarily to be included in the ordinary course of instruction given to every medical student.

I am entirely opposed to the views of those theorists and idealists who would still further weigh down the already greatly overtaxed medical student by insisting on his studying during his five years curriculum all that is known by experts concerning personal and public health; who would introduce a mass of "field work" as well as courses of lectures into the ordinary medical student's career; and who deplore the fact that these students before they leave the schools to enter into practice are without a knowledge of such items as the local arrangements of Poor-law treatment, the practical operation of the Midwives Act, every detail of factory hygiene, of the sanitary machinery for dealing with tuberculosis in the district in which they are going to live, and of the numerous instruments and agencies provided by the State for the alleviation of an artisan's family in the event of sickness.

This exorbitant demand on student study reminds one of Francis Bacon, three centuries ago, aiming at the acquisition of a knowledge of all that was known or knowable in his day; or of Rabelais' fable of Gargantua urging his giant son Pantagruel to defend, successfully against all comers, in the crossways of the city, no less than 9764 theses, and then

to return home to receive blessing before his giant father died.

I know of no criticism more misleading for the layman, more unfair to medical teachers, and so unappreciative of their ever-increasing, self-sacrificing, unaided, and well-nigh hopeless efforts to keep medical education level with the knowledge of the day, as that on page 12 of Sir George Newman's Memorandum on Medical Education in England, addressed to the President of the Board of Education. His remarks on the disparity between the growth of medical education and the growth of medicine would, I feel sure, have been tempered by some extenuating reasons had the author reflected for a moment that there is a limit to the mental receptivity within a given period of even the most brilliant students, and that it is impossible to compress the contents of a big and overcrowded store-room into the dimensions, say, of a table drawer of ordinary capacity.

But in spite of the inevitable limitations of the five years curriculum and of the shortcomings in the medical student's education on which so much stress is laid, the young practitioner, with such scanty knowledge as he has picked up at his medical school, soon learns by experience in the working of a practice what is expected and actually required of him; and, with the exception of those who have undergone special training to fit them for holding public health appointments, he knows a great deal better than consultants, and members of college councils, and university faculties, how to carry out the practical details of preventive medicine.

REPRESENTATION OF VIEWS OF GENERAL PRACTITIONERS.

But, be this as it may, it is essential for the smooth and efficient administration of any State Medical Service that the voice of the great body of general practitioners should be heard and more readily listened to in future than has been the case in the past. It is but reasonable that they should have ample opportunity to make their views known about the terms and conditions under which their own services in future are to be rendered. It is as much, or more, in the interest of the State as in that of the medical profession itself that these terms and conditions should be based upon a sound, satisfactory, and honourable footing. It is also very desirable for the successful working of any national scheme relating to the medical care of the poor, to health insurance, preventive medicine, and local sanitary measures, as well as for the satisfactory enactment of medico-political reforms, that there should be a clear understanding and well-directed co-operation between the general practitioners all over the country and the Members of Parliament and other laymen who take a genuine interest in the national struggle against disease. This is, however, not likely to be the case unless the views of the mass of the profession can, somehow, be brought into continuous and uncensored touch with Parliament, with the Health Minister, and, if desired, with the heads of other departments of Government.

The practice which has hitherto prevailed, in so far as the Government has sought the advice or guidance of any medical men at all other than those in the central government employ, has been to consult the Presidents or Councils of the Royal Colleges, the General Medical Council, and the so-called heads of the profession. This plan, however, has not given general satisfaction in the profession; and on this point I should like to make a few remarks. It is unreasonable, indeed senseless, to pour out vials of wrath and columns of contemptuous abuse on those institutions, as the manner of some is to do. The Royal College of Surgeons of England, for example, has been frequently condemned because it will not dissipate a part of its income in a costly annual ballot by post of its many thousands of members, and will not comply with the demands of an infinitely little band of agitators who clamour for votes and seats in the Council so that they may have the use of the College funds to improve their status and pursue their claims to what they choose to call their professional rights. Such agitations if successful would destroy the usefulness of the College, and as it is they stir up, or tend to stir up, ill feeling in the profession against that great and honourable corporation.

The General Medical Council is from time to time reproached, reprovied, and belittled because it will not infringe the Acts of Parliament and its standing orders by putting upon the Medical Register some skilful and popular but non-qualified "surgical manipulator," or by restoring to the

Register the names of doctors who continue to associate themselves in the treatment of patients with persons other than legally qualified medical men.

THE ROYAL COLLEGES AND GENERAL MEDICAL COUNCIL.

The Colleges and the General Medical Council have very important public and professional duties to discharge. The Royal Colleges, for generations before the Universities took any part in the education of the general practitioners, or the passing of the Medical Acts which established the Medical Council as the authority in medical education and registration for the United Kingdom, were the pioneer directors of medical education and examination of the great bulk of the medical practitioners of the country and its public services. They took an early, and have ever since taken an active and important part in providing for research work. They have valuable libraries and museums and lectureships to guard and maintain, which are accessible to any member of the profession and available for the use of general visitors on application. The Museum of the Royal College of Surgeons of England is unequalled in the world for the importance, the variety, and the extent of its collections. Upon these and upon the buildings which contain them £163,000 have been spent, of which the British Government has provided £57,000 and the College of Surgeons £106,000. But this large sum gives a very inadequate idea of what the College has expended in adding to and in the preservation of the contents of the museum. The superintendence of the museum is confided by the Council to a committee of its own members, who are responsible to it and to a body of trustees, some of whom are appointed by the Government and others by the College.

The General Medical Council, besides controlling the discipline of the profession and the medical education and registration of the United Kingdom, coördinates the education and examinations in the dominions, colonies, and elsewhere, where reciprocity of registration is desired; and from time to time urges upon the Privy Council the need for legislation concerning medical and dental practice. Then there are the Royal Society of Medicine, the Medical Society of London, and other similar societies in London and the great cities of the United Kingdom whose function is the reading and discussion of papers and the interchange of opinions on medical and surgical subjects and the collateral sciences.

But while recognising the very important functions of the General Medical Council, of the Royal Colleges, and of the learned medical societies, and while not in the least degree disparaging or depreciating the admirable manner in which those bodies discharge their functions, and without attempting to dispute the wisdom of their own methods of administration or control, there is no denying that the Royal Colleges and the medical societies are not the best qualified bodies to give advice on most subjects of national and local medical administration. They lack that intimate acquaintance with the conditions of life amongst the great masses of the people, either in urban or agricultural districts, which the general practitioners possess. Nor do these institutions act wisely and in the best interests of the nation by refusing to coöperate in honest, disinterested efforts to found an independent consultative and advisory board to keep watch over all matters concerning medical legislation.

SUGGESTED SCHEME.

What is wanted now, and will be none the less needed after the setting up of a Ministry of Health, with its advisory committee composed of salaried and State-appointed members, is a committee composed of unpaid and unofficial delegates representing all the various sections and corporations of the profession. These delegates might be elected either at a general meeting open to the whole profession, or by ballot conducted through the post, or, if local or branch committees are established throughout the country, by the election by these local committees of their own delegate or delegates. These representatives would bring together the knowledge and experience of their several sections and institutions. The function of this committee would be to coördinate, coöperate, criticise, and confer, but would have no executive power. The committee should be privileged, however, to present reports containing their considered opinions and conclusions to the Health Minister, to the Prime Minister, or to Parliament direct.

At present no such body exists. The British Medical Association is the nearest approach to it. But it was not

founded to exercise, and does not profess that it exercises exclusively, or as its principal object, any such function; nor does it embrace more than one-half of the profession; and, whether rightly or wrongly, it is very generally considered to be engaged in directing its efforts at least as much, if not more, in advancing the personal and collective professional interests of its members as in safeguarding and promoting national objects.

THE MEDICAL PARLIAMENTARY COMMITTEE.

It was partly with the view of ultimately setting on foot such a committee as I have just outlined that a large meeting, open to the whole medical profession, was held in Steinway Hall on Oct. 1st, 1918. It was hoped that the profession would become alive to the fact that it is the duty of every medical man to further any medical policy for the benefit of the community, and to join in any scheme for employing the full powers of medical and sanitary science to add to the general efficiency of the State.

It was foreseen that for this purpose the unanimous coöperation of the profession is essential. It was urged that in order that the matured views of responsible medical men might be adequately brought to the notice of the public there ought to be a larger number of medical men in the House of Commons. With these ends in view a committee was there and then elected, with power to add to its numbers. This committee is now known as the "Medical Parliamentary Committee." Its composition makes it representative of consultants, general practitioners, and many medical organisations. But the Royal Colleges, and the Royal Society of Medicine, and the Medical Society of London, so far, stand aloof. It is to be hoped that in time all these bodies will come into line, and that the "Medical Parliamentary Committee" will represent every section and every organisation of the profession, with branch committees keeping in touch with provincial and county councils, and local sanitary authorities throughout the Kingdom.

SUMMARY.

The points I have endeavoured to bring out in this article are the following:—

1. That there is not, and never has been in this country, what is very badly wanted—namely, a Medical Federation such as the recently constituted Medical Parliamentary Committee aims at becoming, the primary or exclusive objects of which should be to bring to the notice of Parliament and the nation the importance of medical knowledge and medical service in advancing the good of the State, the proper sanitation of its villages, towns, and cities, the virility of its manhood, and the general health of its people; to instruct the legislature and the public as to how this knowledge is to be applied and this service rendered with the utmost efficiency; to criticise proposals, to offer advice, and to give practical assistance in regard to measures having relation to the particular functions of the profession, when under consideration with a legislative or administrative object; and to offer suggestions and advice as to reforms which from time to time may be needed to keep the standard of public service on a level with progressive medical science. The Medical Federation, in fact, should be an unattached advisory board to the Minister of Health and his official advisory committee, without any independent executive power, but having a recognised moral, if not a statutory right to be consulted on all measures or changes affecting the medical and sanitary services of the State, and with the privilege of making uncensored reports, when necessary, direct to Parliament or to the Prime Minister.

2. That before such Medical Federation can be set up the existing tendency to professional segregation, or self-imposed isolation, and individualism, and the deeply rooted professional prejudice against taking part in any public movement whatever of a political character must be greatly modified if not abandoned.

3. That the progress of science, the development and extension of medical knowledge, and the socialistic demands of modern democracy make such a change in the outlook and relations of the medical profession necessary—and, indeed, essential as being conducive to the commonweal.

4. That the Medical Federation here suggested need not, and, indeed, cannot, and ought not to attempt to interfere with or to be in any way mixed up with the ordinary and special functions of existing corporate bodies and institutions;

though it deserves to have the encouragement, good will, coöperation, and material assistance of all of them.

5. That the Medical Federation, or Medical Parliamentary Committee, ought not to concern itself with functions such as those exercised by the British Medical Association. It should have nothing of the nature of a trade union. It should not be looking after and promoting, by Parliamentary and other committees, the interests of its members, or insuring their lives, or laying down and enforcing the terms of medical appointments, or attempting to direct the ethics of the profession. And though its membership would be medical and scientific it should not be what is commonly understood by the term "a scientific society." It therefore should not, like the Royal Society of Medicine and other kindred societies, direct its energies to the advancement and development of the science and art of medicine, or to discussing unsettled questions relating to new discoveries or methods. It should, in fact, be a political association with its sphere of "politics" strictly confined to the promotion, improvement, and authoritative criticism of, and to expressing its matured responsible judgments and its deliberate unified conclusions upon, those matters as to which it ought to be both the duty and the privilege of the profession to give counsel and render service for the benefit of the community at large. It should substitute for the sporadically and occasionally sought opinion of college councils and the so-called heads or leaders of the profession the opinion of the main body of the profession, as being the regular recognised source of instruction and guidance for Ministers, Parliament, and the public.

6. The Medical Federation should be thoroughly representative of the Royal Colleges, the medical societies, the British Medical Association (whose coöperation, detached from its other functions and spheres of usefulness would be of the utmost help and importance), and very especially of the general practitioners throughout the kingdom, whose delegates should be nominated exclusively by themselves.

7. For its success, unity in the profession, and on the part of the federation itself, moderation and restraint of differences in its consultative procedures, and suppression of discordant voices and actions in its public utterances and activities are requisite; and when successfully established the Federation, or Medical Parliamentary Committee, should encourage the formation of branches, or local advisory committees of a precisely similar character, and exercising a similar guiding, suggesting, and persuasive influence over the county and borough councils in their respective neighbourhoods, as the parent association should aim at exercising over the nation and the legislature.

SIGNIFICANCE OF AN INVERTED "T" IN THE FIRST LEAD OF THE CARDIOGRAM.

By I. HARRIS, M.D., L.R.C.P.,

FROM THE RADIO-THERAPEUTIC DEPARTMENT, DAVID LEWIS
NORTHERN HOSPITAL, LIVERPOOL.

THE inversion of T in electrograms in the third lead has no particular significance; in the second it is a sign of a grave myocardial condition. The information obtainable in electrocardiographic literature in regard to the meaning of inverted T in lead I. is very meagre. The table below is made up from records of out-patients attending a general medical department. An electro-cardiogram was taken from those cases who complained of dyspnoea on exertion, fainting fits, oedema, without showing any obvious causes accounting for the symptoms. However, a number of cases of valvular disease are contained in the table.

T in I. lead inverted in all these cases. An inversion of T in the I. lead is often found in cases who are under the influence of digitalis.¹ Cases who were complaining of dyspnoea, &c., did not always show an inversion of T. On the other hand, all those cases who showed an inversion of T in the first lead have invariably shown one or more symptoms usually associated with defective heart action. The conclusion is that an inverted T in the first lead is a reliable sign of a damaged heart muscle.

I am indebted to the Medical Board, Northern Hospital, for permission to use material in connexion with this note.

Table of 40 Medical Out-patients in whom an Electrogram was taken. The last column records the inversion or not of the first lead.

PRELIMINARY REPORT ON
THE PRESENCE OF A FILTER-PASSING
VIRUS IN CERTAIN DISEASES,

WITH ESPECIAL REFERENCE TO TRENCH FEVER,
INFLUENZA AND NEPHRITIS.

BY MAJOR-GENERAL SIR JOHN ROSE BRADFORD, A.M.S.;
CAPTAIN E. F. BASHFORD,* R.A.M.C.;

AND

CAPTAIN J. A. WILSON, R.A.M.C.

(A Report presented to the Director-General Medical Services,
British Armies in France.)

DURING the autumn of 1917, and the spring and summer of 1918, observations were carried out by us on the pathology of acute infective polyneuritis. These resulted in the detection, isolation, and culture by the Noguchi method, of an organism that reproduced the malady when inoculated into animals, and further, this organism was recovered by culture from such experimental animals. The details of this work will be published in the forthcoming number of the *Quarterly Journal of Medicine* and therefore need not be considered here. The causative organism of polyneuritis belongs to the group known as "filter-passers," in that the virus will pass through certain filters, although it is not a filter-passer in the sense that some other organisms are, as it does not pass through certain filters with very fine pores.

The satisfactory results obtained in the study of polyneuritis led naturally to the same method that had proved so successful with this disease being applied to other diseases where there was either evidence or suspicion that the causative agent was a filter-passer. A considerable number of such diseases have been investigated on these lines during the last six months in the laboratories attached to certain hospitals in the Etaples area.

Captain J. A. Wilson conducted the whole of the bacteriological portion of these inquiries in the laboratory of No. 20 General Hospital. Further, the observations on trench fever mentioned below were all made in this hospital, and Major Frank Clayton, R.A.M.C., had charge of the clinical observations on the volunteers inoculated with the virus of trench fever.

Captain Peacock controlled the whole of the entomological part of the inquiry, and more especially the provision of clean lice to control observations on infected lice.

The experimental work on animals and the histological work on the lesions so produced has been carried out by Captain Bashford in the special laboratory attached to the Observation Hut at No. 26 General Hospital. The present report is merely a preliminary statement as to certain results achieved, the full details, clinical, experimental, and histological, will be published later.

Trench fever was one of the first diseases examined at the suggestion of Captain Wilson. Other observers have adduced evidence showing that the virus of this disease belonged to the group of filter-passers.

Trench fever.—The virus isolated in trench fever consists of minute coccus-like bodies, grouped in pairs, with the opposing surfaces flattened, and varying in size from 0.3μ to 0.5μ . It is Gram-positive and stains readily if the film preparations are washed in ether before the stain is applied. It passes through Berkefeld N. and V. filters, and also through Masson porcelain filters, and can be cultivated from such filtrates. It resists heating to a temperature of 56°C . for 30 minutes, and it is an anaerobe.

This organism has been recovered by culture from the blood in 11 out of 15 cases of trench fever examined during the pyretic stage, and in 3 out of 8 cases examined when apyretic. It was not found in over 40 control cases where blood culture with the same technique was carried out.

A similar organism was recovered from four separate supplies of infected louse excreta kindly supplied to us by Sir David Bruce.

It was not found in 31 specimens of excreta from batches of clean lice.

The culture obtained either from the blood of man or from louse excreta, when inoculated by scarification into

man, produces a mild illness, and the organism can be recovered from the blood by culture during such illness, and also from clean lice fed on the patient during the illness.

Influenza.—The virus isolated in cases of influenza consists of very minute rounded coccus-like bodies, varying from 0.15μ to 0.5μ . It is Gram-positive, and passes through Berkefeld N. and V. filters and Masson porcelain filter. It is an anaerobe, and resists heating to 56°C . for 30 minutes.

It has been isolated by culture from the blood in 6 out of 9 cases examined, from the sputum in 6 out of 6 examined, from pleural fluid in 4 out of 4 examined, and from the cerebro-spinal fluid in the only case so examined. It has also been isolated from the lymphatic glands post mortem in the only two cases examined. This organism can not only be grown from the blood, and from exudates, but it can also be seen in stained films prepared from exudates—e.g., sputum, pleural fluid, cerebro-spinal fluid.

The culture (second generation) when inoculated into animals subdurally, or intravenously, produces illness in guinea-pigs and monkeys, and on post-mortem examination the following lesions have been found: extensive lobular pneumonia with hæmorrhages, some nephritis, myocardial and hepatic lesions, such as extreme congestion, interstitial hæmorrhages of small size, and fatty degeneration. Passage experiments done from such animals when slightly ill, by injecting their blood, bile, &c., into healthy animals, causes in these more severe and even fatal illness, and post mortem the same lesions are found. The organism has been recovered by culture from the tissues of such experimental animals.

Nephritis.—Up to the present time (January, 1919) only one variety of nephritis has been investigated—i.e., that characterised by the presence of pyrexia and hæmaturia at the onset.

The virus isolated in such cases of nephritis consists of a round coccus-like body varying from 0.3μ to 0.6μ in size, and in culture often occurring in the form of short chains of four individuals. The same organism may be seen in urinary sediments either singly or in pairs. It is Gram-positive and passes through Berkefeld N. and V. filters, and also through the Masson porcelain filter. It is an anaerobe and resists heating to 56°C . for 30 minutes.

It has been isolated from the blood in 6 out of 9 cases examined and from the urine in 7 cases. The culture (second generation) when inoculated into animals produces nephritis in monkeys and guinea-pigs. In monkeys this can be determined not only by post-mortem examination, but also clinically, since the urine contains blood, albumin, and casts. In both guinea-pigs and monkeys extensive lesions, glomerular and tubular, are found on microscopic examination. In severe cases pulmonary lesions are also present.

The organism has been recovered by culture from the tissues of the animals experimentally inoculated.

These three diseases are those that have been most studied as yet, but organisms of the same group, although differing from one another, have been recovered by culture in a number of other diseases of obscure etiology. In most of these no adequate experimental work has been possible up to the present, and in others it is incomplete owing to insufficient time having elapsed to establish results with certainty. Amongst the more important diseases where true "filter-passing" organisms have been isolated by culture from the blood and seen in suitably stained films mumps, measles, rose measles, and typhus, may be mentioned. In mumps four cases have been examined, and all gave the same positive result. Two cases of typhus have been examined, but as yet it has only been possible to get material from one each of measles and rose measles.

An organism allied apparently to that of polyneuritis has been isolated from brain tissue in cases of encephalitis lethargica, both from material obtained from England and also from cases observed in the Army in France. A considerable amount of histological work has been done on the lesions present in animals (monkeys) successfully inoculated with these cultures. These results will be published later.

If the organisms found in polyneuritis and encephalitis are excluded, all the others have many points in common and possibly belong to one group. Although exceedingly small, they present individual differences in their morphology, and in their mode of growth in culture. These details must be reserved for fuller and later publication.

A STUDY OF THE SUSPENSION TREATMENT OF FRACTURES OF THE THIGH.

BY WILLIAM H. JOHNSTON, B.A. (N.Z.), M.D.,
CH. B. EDIN.,

CAPTAIN, R.A.M.C. (T.C.); LATE ASSISTANT SURGICAL REGISTRAR, SPECIAL
MILITARY SURGICAL SECTION, READING WAR HOSPITAL.

AT the moment of writing several thousand cases of gunshot fracture of the thigh are under treatment in our hospitals. Some have been recently wounded, most have passed the critical septic stage, all have still to regain in a greater or less degree the proper functional use of their limbs.

Our ideals have been to eliminate sepsis by early radical operative procedures, to aim at rapid and complete repair of bone, and to secure unrestricted movement of all joints with the best possible nutrition of the limb. The ultimate functional efficiency of the limb will depend largely upon the severity of the lesion, the type and the degree of the infection, and the coefficient of recuperative power, especially with regard to bone. Those cases where, as a result of these factors, union is long delayed will naturally present the most difficulty, for the limb must, in such cases, be subjected for the longest periods to fixation and extension with detrimental results. The muscles of the thigh may become indurated with inflammatory products, bound up in callus or adherent to scar tissue. The tissues in and around the knee-joint may undergo definite pathological changes resulting in impairment of function, the restoration of which superimposes upon the treatment of the fracture, a tedious and difficult process.

Hostilities have ceased, but our task is but half accomplished. It must be admitted that at least one of the questions we have to face is the problem of delayed union. The percentage of such cases is unavoidably high, and the treatment must be a protracted one. Bone-grafting opens up a new field here, but our real difficulty will lie in conserving nutrition and movements, in maintaining equality of length and natural alignment during the intervening months. This being the case, the writer may be pardoned for treading upon ground which, after four years of war, may rightly be regarded as well explored.

A Résumé of Principles and Methods.

In our treatment to-day of fractured femurs there are broadly two principles involved, associated with two divergent methods. The first, associated with Thomas and the Thomas splint, is that of complete reduction, *ab initio*, and immediate and continuous fixation. The second, associated with the methods of suspension and the employment of weights and pulleys, is that of gradual reduction. Both employ axial traction on the limb. Both aim at complete muscle fatigue.

In the former muscle fatigue is obtained by a concentrated process by which the muscular resistance is overwhelmed, the displaced bones reduced to position, and the results gained rigidly maintained from the beginning. This process is ushered in by deep general anaesthesia or by spinal anaesthesia, ensuring absolute flaccidity of the muscles involved, which are never permitted to resume their deforming action on the fragments. Reducing and counter-reducing forces are concentrated upon the limb by the ingenious mechanism of the Thomas splint. Muscular contraction, while it lasts, acts against two rigidly fixed points—namely, the tuber ischii and the distal end of the splint.

In the second method a superstructure is necessary, which is solid, which may lie upon the bed, be built up from it,

surround or surmount it. The simplest type may be found in the wire cradle splint of Hey Groves, and the most complex in the Gassette frame with travelling overhead gear, multiple uprights and crossbars, and a multiplicity of cords, pulleys, and weights. The commonest type is, perhaps, a modification of the well-known Hodgen splint.

This system, unlike the former, is not ushered in as a rule with complete reduction under anaesthesia. Reduction is provided by a weight exerting what is believed to be a constant pull acting over a pulley, and counter-reduction is gained by elevating the bed and by throwing in the body weight. It is claimed for this method that it allows greater freedom of movements in bed and better access for dressing.

With regard to these two systems, the following points are to be made:—

1. The principle of the Thomas splint is the only tenable one in so far as complete reduction should always be obtained as the first step in any method of treatment, and it can be done only under deep anaesthesia with or without operative interference.

2. There is no doubt that by securing this, uncomplicated cases properly treated on the Thomas splint so speedily acquire union that movements of the knee-joint are little impaired.

3. By the failure to secure complete reduction *ab initio* the suspension system, often handicapped from the outset in overcoming resisting muscles, has perforce to resort to a reducing force acting over a longer period than would otherwise be necessary.

4. A failure to secure and maintain complete reduction in either method undoubtedly prolongs the fixation of the limb, and in many cases the immobilisation of the knee-joint.

5. In the early stage of treatment movements at the knee can be secured in both these methods only by releasing for the time the reducing forces, a procedure which by virtue of the mechanism of the appliances involved would immediately lose control of the broken ends of the bone, destroy immobilisation of the fracture area, and produce pain.

Direct Bone Fixation Methods (Calipers, Screw-clamps, Transfixion Pins, &c.).

This method of applying the reducing force directly to the femoral condyles is now widely used. It implies the use of a superstructure and the suspension of the limb. Splinting of some sort is applied to the thigh, but the leg is left free to move from a position of full extension through 90° of flexion on the thigh. Many ingenious devices are in use by which these movements are procured, and some surgeons go so far as to say that every fracture of the femur, irrespective of site, should be treated by the use of calipers.

The method is theoretically the simplest and most economical of all methods of reduction. The reducing force is directly applied to the femur itself, and, irrespective of the movements of the pelvis or the leg, must act always along its axis.

In any other method whenever the leg leaves the position of full extension the reducing force acts indirectly via the knee-joint, and therefore at a mechanical disadvantage. Wherever this method is used movements of the leg should

always be provided for by the mechanism adopted, and the limb should never be rigidly fixed from hip to ankle in a splint of any kind.

On Adhesive Plaster, Glue, &c.

Perhaps the commonest method of affixing the reducing force to the limb is the old method of gluing or sticking bilateral bands of suitable material along the skin of the limb. If the limb be treated in the fully extended position throughout the adhesive plaster can be carried up to, or

Methods 1 and 2, Case A. $D-B$, resultant of $A-B$ and $C-B$. z , turning moment about pelvis due to gravity. y , tension at site of fracture. x , tension on cord over pulley.

above, the site of the fracture, and the force will act directly along the axis of the femur—i.e., most economically. There is a further economy in the available skin.

If, however, the limb be flexed at the knee the adhesive should be carried to a point below the knee, and the force then acts indirectly along the femoral axis and at a mechanical disadvantage—i.e., uneconomically. There is also a loss of available skin. The trouble due to the use of adhesive plaster has been great. Notwithstanding the greatest care in its application and supervision, this trouble is still present. It is certain that such a method of affixing a reducing force to a limb will not permit of haphazard methods with pulleys and weights. It is a crude method at best.

It is suggested that much of the trouble could be avoided by the strictest economy in the application of force. Thus:

1. Weights are often applied by guess-work at angles mathematically uneconomical.
2. A resolution of forces employed in a given case would give a resultant upon the femur not at all in proportion to the total weights used.
3. Heavy weights are often left acting upon the adhesive and skin long after the complete reduction of the femur has

Method 1, Case B. x and y , less than x and y in Fig. 2. $z = z$ in Fig. 2.

been accomplished, when very much lighter weights are all that is necessary to maintain the results gained. This may be due to lack of observation, failure to measure the limb regularly and to make repeated radiographic examinations.

4. A change of position in bed may throw the system out of gear, cause variation in the reducing force, and allow of relaxation and fresh displacement at the fracture site. To overcome this heavier weights are again resorted to, with additional strain upon the skin.

If attention be paid to these details a great deal of the above trouble may be avoided. The question to be asked is—What is the minimum weight that can be used to produce in the shortest time the result aimed at? What is the correct way of applying it? The answer is to be found in the study of the mechanics of suspension.

Experimental Study of Certain Methods and Fallacies of Suspension.

The efficiency of the Hodgen splint lies in the fact that the forces acting upon the rigid framework from above are divided into two sets: (a) those acting along the limb from hip to heel (direction); (b) those acting from below upwards. The former are transmitted by the bands of adhesive fixed to the distal end of the splint and applied to the skin of the leg—a tension effect. The latter are transmitted to the limb by the supporting crossbands of the splint—a pressure effect. There is thus a distribution of the reducing force into a tension and a pressure, each distributed more or less equably along the limb.

Consider here three of the commonest suspension methods in which the Hodgen splint, or modifications of it, are used.

The apparatus (Fig. 1), constructed of wood, was used as a means of checking the geometrical results shown below. The broken femur is represented by two wooden blocks, connected on each side by small spring balances, each capable of registering 20 lb. tension. By its use the theoretical findings were in every case substantiated.

Method 1.

Case A.—The first system investigated was the method originally described in the text-books as the Hodgen splint. This is shown diagrammatically in Fig. 2. The limb is suspended by one cord passing over a single pulley, B ; the latter

Method 2, Case B. $x = x$ in Fig. 2. y_2 less than y in Fig. 2, greater than y in Fig. 3. $z = z$ in Figs. 2 and 3.

is rigidly fixed to the overhead bar or upright. A large spring balance was let into the fixing cord. The mechanism of this case may be briefly solved as follows:—

ABC is a continuous cord running over the pulley. Therefore, tension in AB equals tension in BC . The resultant tension must bisect the angle ABC , and must therefore act along BD . Gravity produces a turning moment upon the pelvis. Let this force be z , acting through D . The forces x and z must have a resultant, acting parallel with the axis of the femur. Draw Dy through D parallel with the femur, and taking Dx any convenient length, complete the parallelogram $Dxyz$.

If x in direction and magnitude represents the tension in the fixed cord, then according to the parallelogram of forces, y must represent in direction and magnitude the reducing force upon the femur. Therefore y lbs. are exerted upon the balances at the fracture site by a tension of x lbs. in the fixed cord (see the large balance). Note, further, that y is not acting directly along the axis of the femur but parallel with it, and that y is a little more than half of x .

Case B.—Now let the patient move towards the foot of the bed, say 6 inches, all other fixtures being unaltered. What happens is demonstrated in Fig. 3, which is drawn exactly to scale with Fig. 1. It will be observed that the only force which does not alter in both direction and magnitude is the force of gravity, z . The new resultant, y , is greatly reduced, certainly by more than half, and the angle of the femur to the bed is, of course, altered. The deduction from the above is that by a movement of 6 inches, downward towards the foot of the bed, there is loss of 60 per cent. tension produced upon the femur. In practice, the patient soon finds this out. Considerable elevation of the bed often fails to check this. The practice of elevating the foot of the bed considerably is

to be condemned. It is quite unnecessary and can be obviated by varying the angle between the femoral axis and the horizontal. The nearer the femur approaches the vertical position the greater becomes the counter-reducing force of body weight. This was recognised by Scudder.

Method 2.

Case A (patient stationary).—Next consider the system where (see Fig. 2) instead of the cord being fixed to the upright, a second pulley is supplied and a weight of x lbs. is suspended to the end of the cord—i.e., the same weight as the tension shown upon the balance in the case of the fixed cord. It is unnecessary to say that, in this case, everything remains as in Case A, Method 1, provided the patient remains stationary in bed.

Case B (patient moves).—Now again, let the patient move towards the foot of the bed, say 6 inches: Fig. 4, drawn to same scale as former figures, demonstrates the change of forces, both in the direction and magnitude, which occurs. The direction and magnitude of all forces save that of gravity, z , change. y_2 , the resultant force, is greater than in Method 1, Case B (Fig. 3), and less than in Method 2, Case A (Fig. 2); in other words the second pulley with weight is an improvement and saves a certain amount of loss of tension on the femur due to movement of the pelvis. If the patient moves towards the foot of the bed extra weight must be added to the cord, therefore, to maintain uniform tension.

Method 3.

Case A.—One frequently sees a limb suspended in a Thomas splint, bent at the knee in varying angles with the adhesive strapping secured to the distal end of the splint. The ring of the splint is usually in loose apposition to the

Method 3, Case A.

Method 3, Case B.

gluteal fold and tuber ischii and the main reducing force is applied by weight and pulley from a superstructure to the distal end of the splint.

A similar method is also frequently seen with the Hodgen splint. It is not suspended as in Figs. 2, 3, and 4, but by two or more upright or oblique cords applied at either end of the splint and one about the middle. The main reducing force is then applied by weight and pulley from a superstructure to the distal end of the splint. These cases are analogous. The Thomas splint is here used merely as a supporting framework for the limb. Diagrams are unnecessary, as they are well-known types.

f lbs. (Fig. 5) acts directly along the axis of the leg. Let it be required to produce f lbs. pull along the axis of the femur. Let a represent f lbs. pull in magnitude and in the required direction. With a as a radius, describe arc sc . Complete the parallelogram $orrc$.

To get a resultant equal to f lbs. a second additional weight, it will be seen, must be added, represented in direction and magnitude by or and represented diagrammatically by x lbs. over a second pulley. Vary the angle of the splint at the knee (and from experience this is a very variable angle) and both the magnitude and direction of the force or must vary. The weight y represents any number of tensions suspending the limb, applied along the splint and counteracted by gravity z —i.e., the limb is suspended in equipoise.

The importance of this upon the two types of cases just cited is that: 1. The weight f acting over the pulley produces only a little more than half its weight as a direct tension along the axis of the thigh. 2. In all such cases as the above, a second weight varying in direction and magnitude with the leg-thigh angle is necessary to secure a resultant pull along the axis of the femur equal to the pull applied at the end of the splint. 3. This is irrespective of the weight already in use to secure equipoise on the limb. Therefore, whatever angle is selected at the knee in this type of rigid splint, the additional force and its angle of application should always be carefully calculated before use.

Case B (patient moves).—Fig. 6 shows the position when patient moves towards the foot of the bed. The drawing is to scale with Fig. 5. It will be seen that the direction and magnitude of the force y alters. Part of this force formerly used to secure equipoise now acts along the leg in opposition to f , and to this extent gravity z is unopposed. Hence the

distal end of the splint tends to drop. The force x alters very little in magnitude but its direction is changed, and hence the new resultant a alters appreciably in magnitude. The inference here is that even with the additional weight x a change of position in bed produces a falling off in the resultant force, and at the same time a tendency for the limb to rotate downwards upon the pelvis.

To sum up: The Hodgen splint, as used in Figs. 3 and 4, and the Hodgen and Thomas splint used as in Fig. 6, fail to give a constancy of the reducing force upon the site of the fracture. Movement of the patient up or down in the bed also produces variations in the accessory forces which may be applied. (See Fig. 6.) In all, flexion of the thigh is possible, but causes a variation in the force of reduction acting upon the fracture site. In all, movements at the knee-joint are impossible without throwing the apparatus out of gear.

A Mechanical Device for Securing Free Movement at the Knee without necessarily using Calipers, Clamps, Transfixion Pins, &c.

In the methods discussed and in other modifications, the forces employed are often multiple and they are not applied directly along the axis of the femur. Eventually they are all resolved, some in roundabout ways, so that part at least of each force acts in this way. By acting at a mechanical disadvantage greater weights are thus often used to produce a given resultant than there is any necessity to use. The legitimate inference is that in all indirect methods of applying the reducing force there must be:—

1. A mathematically accurate method of arranging the forces so that the maximum resultant is obtained along the femur with the minimum components.
2. An angle of flexion of the leg upon the thigh, which is the most economical angle—i.e., one at which the leg shall bear the strain longer and easier and with less tension and pressure effects than at any other angle.
3. That variation of this angle will produce a variable but proportionate distribution of the forces acting upon the knee and leg and consequently a conservation of skin.

This can be proved as follows:—

Let AB (Fig. 7) intersect CD at right angles. With centre E and radius EF describe the circle $FGHK$. Take any point L between K and B on AB . Join LF and LH , make EM equal to EL , and join FM and HM . The figure $FLHM$ is

a parallelogram. Let LB represent a force divided into two equal forces LF and LH . The resultant force is LM (in direction and magnitude). Now let the line CD assume any other angle with AB —e.g., $C'D'$ —at an angle of 45° . Let the points where $C'D'$ intersects the circle be F' and H' . Join LF' and LH' , and $F'M$ and $H'M$. The figure $L'F'MH'$ can be proved to be a parallelogram.

Observe again that if LB represent a force dividing into two components LF' and LH' respectively, the new resultant is still LM in direction and magnitude.

And so it can be proved that whatever angle CD makes with AB , the resultant force must always lie along the line AB and be represented in direction and magnitude by LM , which is the constant diagonal of a varying parallelogram.

Apply the above, then, to the treatment of a fractured femur. Let AE represent the thigh, E the knee-joint, and

ED the leg, and let it be imagined that these lines represent the iron framework of a splint. Suppose the rigid bar ED be prolonged in the direction of EC to F , so that EF equals EH . Let FLH be a cord passing over a pulley at L , and let LB represent the main cord passing over a fixed pulley overhead. Let there be a moveable hinge-joint at E .

Case 1.—Let the leg ED be flexed at 90° to the thigh. A force LB , acting equally along the two cords to the points F and H , equidistant from E , produces obviously a resultant LM acting perpendicularly to the axis of the leg.

Case 2.—Let the leg $E D$ take the position $E D'$ —i.e., at an angle of 135° to the thigh. The iron framework of the leg assumes the line $C' E D'$, and the forces $L F'$ and $L H'$ along these cords are now unequal. But the resultant $L M$ (vide parallelogram of forces $L F' M H'$) is the same in direction and magnitude. Note, however, that the resultant $L M$ now acts at an angle of 45° with $E D'$, and we can resolve it into two sets of forces, one acting along $E D'$ from E to D' , and the other perpendicularly from below against $E D'$. It is obvious that these two sets of forces must at this angle be equal.

As the angle DED' increases the tension force acting along ED' proportionately increases, and the pressure force acting

FIG. 8.

2. These movements must be so controlled that whilst they are being carried out the reducing force acting upon the femur shall not vary.

3. The reducing force must be the most economical one possible—i.e., it must be applied along the axis of the femur.

4. Movements of the pelvis shall not throw the system out of gear and alter forces in direction and magnitude—i.e., the angle of the thigh to the horizontal should be capable of variation without affecting the main reducing force applied to the femur.

5. The thigh must be sufficiently elevated above the horizontal to secure adequate counter-reduction from body-weight without raising the foot of the bed.

6. Anterior arching of the fractured segments shall be provided for.

The following is the apparatus in question :—

Method of Applying the Splint.

The splint (Fig. 8) is applied by first straightening it out so that the femur frame is in line with the leg-frame. The transverse axis of the knee-joint is next marked upon the limb, and the splint is laid in position, flat on the bed and enclosing the limb. The knee hinge is placed exactly opposite the spot marked. The adhesive plaster which has been applied beforehand to a point just below the knee is now secured by any convenient method to the distal end of the splint (see Fig. 9). Supporting bands of calico or other suitable material about 4 inches wide and carrying 1 inch depth of superimposed wool or Gamgee tissue are next fixed to the side bars, passing beneath the leg. The lower third of the leg should be completely ensheathed in wool and firmly secured between the bars of the leg-frame either by a buckled strap passing over the crest of tibia or by a firm bandage. This constitutes a couple in the turning movements about the knee-joint, and ensures that the leg and leg-frame move as one. The cords *A* and *B* are next fixed as in the diagram and passed over fixed pulleys and attached to their respective weights. With an assistant supporting the thigh, the limb is now elevated and slung in delicate equipoise. This is easily effected by accurately estimating, by a spring balance held in the hand, the exact weight upon each cord necessary to produce a stable and at the same time a delicate equilibrium. The cords *A* and *B* should subsequently be made to act vertically by using a plumb-line before fixing the respective pulleys overhead. This is a matter of great importance, because upon the fineness of these adjustments depends the stability of the leg in any position of flexion selected. Pulleys should be well oiled and at least 1½ to 2 in. in diameter, and so constructed that the cord cannot jam. Lastly, the cord *C*, with wire foot-frame and pulley, is fixed to the leg-frame, as indicated in Fig. 8, and the main reducing weight is applied to this cord passing over a fixed pulley, the latter being placed most conveniently at a point almost vertical to the foot of the bed. The thigh is secured in the femur frame after the manner shown in Figs. 10, 11, and 12, superimposed dressings being used for this purpose (see Fig. 9), but other methods of securing anterior bowing can be used according to the site of the fracture.

Fig. 10 shows the apparatus applied and the manner in which the leg-frame rotates about the knee-hinge at *o*. *A* and *B* weights support the limb in equipoise. The apparatus after rotation remains in the new position without any fixing, as shown by *A*₁ *B*₁ and *A*₂ *B*₂. In the position *A*₂ *B*₂—i.e., full extension—the foot passes into the wire foot-frame, which is designed to permit of this. The reducing force *C* remains unaltered, as also does the angle at the hip, by this rotation. Distributed pressure along the calf (*E*) and pull upon the adhesive (*I*) vary with the angle at the knee. At the angle

FIG. 9.

perpendicularly to ED' proportionately decreases. At length, when ED' comes to lie upon EB —i.e., when the leg is in full extension—the whole reducing force upon the femur is now applied directly along the axis of the leg and thigh.

All this suggests an apparatus in which the following points can be satisfied :—

1. The leg must have complete freedom of movement from full extension to flexion at 90° to the thigh.

FIG. 10.

Author's Method. Flexion of knee joint. Rotation of splint about hinge at *o*. *A* and *B* supporting weight of leg and splint in equipoise, the apparatus after rotation remains in new position as *A*, *B*, and *A*₂, *B*₂. Pull at *C* and angle at hip remain unaltered by this rotation. Pressure at *E* and pull on adhesive at *Y* vary (see force diagrams). Explanatory letters denote same points as in other diagrams.

of 135° they are equal (see midposition). The parallelograms at the side indicate how these forces vary in the three selected positions—i.e., *C* is resolved into *e* and *y*, *e*₁, *y*₁, and *e*₂, *y*₂.

Fig. 11 is a diagrammatical representation of mobility in bed and flexion of the hip. The pelvis may move from *x*₁ to *x*₂, i.e., 30 inches to scale—a large range of movement. The angle θ ₁ changes to θ and then to θ ₂. The leg-frame changes from position *A*₁ *B*₁ to *A* *B*, and then to *A*₂ *B*₂. The reducing forces *C*₁, *C*, and *C*₂ always act along axis of femur. *E* *E* *E* denotes the pressure effect distributed along the calf, and *F* denotes the couple effect produced by the bandage or strap around lower third of leg. *Y* denotes the tension acting along the axis of the leg due to the mechanism of the adhesive plaster fixed to the distal end of the splint.

From this it is evident that, once the position is selected from which it is impossible for the patient to withdraw towards the head of the bed, an adjustment of the overhead fixed pulley transmitting the main reducing force may produce an angle " θ " of the femur with the horizontal, to increase which is for the patient both irksome and difficult.

This position then is the position in which the reducing force is counteracted by the greatest available body-weight, and its effect is similar to that produced by extreme elevation of bed. When the height from mattress line to super-

structure level is 4 ft. 6 in. or over, roving pulleys are quite unnecessary. The fixed pulleys then make such small angles to *A*₁ *A*₂ and *B*₁ *B*₂ that the effect is negligible.

In the apparatus described above (Fig. 12) no new principle is involved. It is a simple adaptation of the Hodgen splint and its efficiency is largely due to the mechanical device at the knee end of the leg-frame whereby a couple effect is produced.

It will be observed that the movements of the knee so distribute the forces acting upon the leg that when one set exerts too much strain or pressure this may immediately be relieved by alterations of the leg-thigh angle. The other set

FIG. 11.

Author's Method. Mobility in bed and flexion at hip. Change of angle θ at hip. *x*₁—*x*₂ = 30 inches, a large range. F.P., fixed pulley. R.P., roving pulleys.

then takes up the difference. Thus by varying the angle at the knee a corresponding variation is produced between the forces acting along the axis of the leg and those acting perpendicularly to it.

Accessory Methods.

The apparatus lends itself to the employment of most of the well-known methods of affixing the reducing force to the limb, thus:—

1. The crest of the tibia may be transfixed by a suitable pin long enough to rest upon the lateral bars of the leg-frame, to which it can be firmly secured. Two such pins may be used, one 3 inches below the tubercle and a second 3 or 4 inches above the ankle-joint. The effect of this will be to do away with any pressure upon the calf posteriorly and to eliminate the necessity of adhesive plaster or glue should the use of such be inadmissible or regarded unfavourably.

2. Two small cups at each upper extremity of the thigh supports are provided for the use of a Steinmann's pin should transfixion of the condyles be preferred.

3. Chutro's or Finocchetto's stirrup may be used in preference to the adhesive plaster, and the attachment can be made to the end of the leg-frame.

4. Calipers can be applied in the usual way, in which case the bars of the leg-frame should be set below the horizontal teeth of the calipers. The cord *C*, with its wire foot-frame, will be fixed directly to the calipers and not to the leg-frame. The rest of the apparatus remains the same.

It must be recognised that it is not always convenient or even possible to use calipers or any of the methods of fixing the reducing force directly to bone, and that in any case there are always a number of surgeons who do not approve of them. That being the case, the above apparatus, it is hoped, may be of use in utilising the older methods to the best advantage.

FIG. 12.

Author's Method. S apparatus as used in wards. *x* pulley carries the weight to head of bed.

AN INTERESTING CASE OF ECTOPIC GESTATION.

By B. T. ROSE, B.Sc., M.B. BIRM., F.R.C.S. EDIN.,
LATE RESIDENT MEDICAL OFFICER OF THE GREAT NORTHERN CENTRAL
HOSPITAL.

With Pathological Description by
ERNEST H. SHAW, M.R.C.P. LOND.,
PATHOLOGIST TO THE GREAT NORTHERN CENTRAL HOSPITAL.

CASES of ectopic gestation are not very rare events in the emergency operation list of a large general hospital. There have been on an average five a year in this hospital during the last ten years. The case, however, which it is desired to note has certain peculiarities which render it of more than usual interest. It is an example of a very early rupture—six weeks' pregnancy only—of the rarest of all types of ectopic pregnancy—viz., that in the interstitial part of the tube; while the difficulty of diagnosis is also worthy of note.

Account of Case.

The patient was 30 years of age, and previously had been quite healthy. She had had no children, but 18 months before she had had an incomplete abortion, which rendered evacuation of the uterus under an anæsthetic necessary. She had suffered occasional attacks of acute pain in the right iliac fossa, which her doctor diagnosed as appendicitis.

On admission, at 11 P.M. on August 16th, the patient stated that she had been quite well until 2 A.M. on the morning of that day, when she was seized with acute pain in the right lower abdomen. The pain was severe while it lasted, but ceased after a short time, to recur again at intervals. There was no sickness and no irregularity of the functions of the bowel or bladder. Menstruation had been quite regular until six weeks ago, so that the period was only 14 days overdue. No hæmorrhage or discharge had occurred from the vagina.

On examination the patient's general condition appeared good. The pulse was fairly rapid—about 98 beats to the minute—while the temperature was 100.2° F. and there

FIG. 1.—The specimen in the fresh state. Note the emerging ectopic pregnancy. $\times 2/3$.

was no marked pallor. The tongue was furred, the breath foul, and sordes were present round the teeth. The abdomen moved well with respiration, there was no rigidity anywhere, but acute tenderness was found localised to the right iliac fossa, with its maximum well below McBurney's point. No tumour could be felt in the abdomen and nothing abnormal by the vagina.

A diagnosis of an inflamed retro-cæcal appendix was made, though it was thought possible that some tubal trouble might be present. Laparotomy was decided upon. On opening the abdomen nothing abnormal was seen until the pelvis was explored with the hand, when a large amount of blood welled up into the wound. This rendering the diagnosis of an ectopic pregnancy probable, the patient was placed in the Trendelenburg position and the pelvic viscera explored. Both tubes seemed quite normal; the uterus, however, was somewhat enlarged, and at the right cornu there was seen what looked like a small mass of blood-clot about the size of a filbert adhering to the uterus. The abdominal incision was enlarged and a partial hysterectomy with right-sided salpingo-oophorectomy performed. The abdomen was closed, a considerable quantity of warm saline being left in the peritoneal sac.

The following description of the specimen removed was kindly written by Dr. Shaw.

Macroscopic.—The specimen consists of the whole length of the Fallopian tube and the lateral angle of the uterus. (Fig. 1.) The outer half of the tube is rather swollen and red, and the isthmus gradually becomes thinner as it approaches the uterus, where it ends in a large ovoid swelling projecting from the uterus. This swelling is about 1 inch in vertical diameter and about $\frac{1}{2}$ of an inch in its other dimensions. It is covered with peritoneum except at the apex, where a small piece of blood-clot protrudes from a small perforation. Blood shows through the peritoneum for some distance round the clot. On section the tumour is seen to be red and solid, and blood is effused into the loose tissues below. Although fairly well-defined, the mass of blood-stained tissue is not limited by a capsule, nor is there any sac or membrane suggesting amnion or chorion. No foetus can be made out.

FIG. 2.—A section of the uterine portion of the Fallopian tube showing chorionic villi in situ. $\times 90$.

Microscopic (Fig. 2).—A section made through the tumour at the site of the perforation shows blood and remains of muscular tissue at the periphery and a tuft of chorionic villi within and also projecting through the hole in the wall. The villi are well formed and are embedded in blood. No decidual tissue is seen in this section.

I have to thank Mr. Mower White, senior surgeon to this hospital, under whom the case was admitted, for his kindness in allowing me to publish the case, and also for the opportunity of operating upon it. I also wish to acknowledge the kindness of Dr. Shaw for his description of the specimen and his help in preserving it.

THE ERADICATION OF LATENT SEPSIS

PREPARATORY TO BONE TRANSPLANTATION IN NON-
UNION OF GUNSHOT FRACTURES OF THE LIMBS.

By HARRY PLATT, M.S. LOND., F.R.C.S. ENG.,

HONORARY SURGEON AND SURGEON IN CHARGE, ORTHOPÆDIC DEPARTMENT, ANCOATS HOSPITAL, MANCHESTER; CAPTAIN, R.A.M.C. (T.);
ORTHOPÆDIC SURGEON IN CHARGE, SPECIAL MILITARY SURGICAL
SECTION, 2ND WESTERN GENERAL HOSPITAL.

THE two outstanding causes of the immediate failure of many bone graft operations for ununited gunshot fractures are the occurrence of infection derived from pre-existing latent foci and the breaking down of ill-nourished skin cicatrices. Experience of such failures has brought about the almost universal practice of postponing a reconstructive bone operation until a considerable period has elapsed from the time of the complete healing of the wounds, and of excising adherent skin scars at a preliminary operation. Six months has been adopted by more or less common consent as an adequate waiting period, but only if during this time physio-therapeutic treatment of the limb has caused no such inflammatory reaction as would indicate the presence of latent sepsis.

The Empirical Basis of the Present Methods.

The probationary period, the exsection of skin scars, and the provocative manoeuvres of the massage and electrical departments form a triad of precautionary measures which

in a great many cases—probably the majority—ensures a successful result for the subsequent bone transplantation. Such a standard of safety is, however, founded on an empirical basis; each one of the three factors may prove untrustworthy.

In the first place a six months period is an arbitrary one, as in a given case the tissues may be sterile at the end of two months or may be still capable of infective reaction as late as nine, or even 12, months after healing. A knowledge of the anatomical situation of latent septic foci in these ununited fractures throws considerable doubt on the ability of physio-therapeutic treatment to produce with certainty a "flare up" when it is remembered that the encysted foci are found in the avascular fibrous tissue between and around the bone ends and in the bone ends themselves. For the same considerations no vaccine or serum test can be expected to afford evidence of any positive value. Finally, there can be no doubt as to the necessity of excising adherent skin scars in the region of the non-union, but in my experience this operation does not go far enough.

Provided the necessary preliminary mobilisation of joints, tendons, and muscles, and the stretching of contractures have been obtained, it is desirable to be able to carry out with safety a bone transplantation where indicated, at the earliest possible date. This is especially desirable in complicated injuries such as combined bone and nerve lesions where operative interference is necessary for the repair of the latter. Furthermore, from the standpoint of the patient the prolonged delaying of an operation is to be avoided, if possible, but this economic factor must not be allowed to exert undue influence in the plea for early operation.

We are confronted with the fact that there is no certain test or combination of tests by means of which one can determine when a limb has reached the stage of safety. It is therefore reasonable to regard every limb with an ununited fracture as capable of an infective reaction at any stage, however remote the time of healing may be. An attempt to effect a radical excision of the area containing the suspected foci in every case before performing the bone graft would seem to be a logical procedure.

A Two-Stage Procedure.

Working on this basis, during the past 18 months I have used a two-stage procedure in bone graft operations in the majority of my cases and have now adopted it as a routine in every case.

Stage 1.—When the wounds have been soundly healed for eight weeks, during which period regular physio-therapeutic treatment has been carried out, the following operation is performed. After an excision of the adherent skin scars the site of the non-union is exposed. The fibrous tissue filling up the gap is excised, together with a slice of the bone ends sufficient to expose vascular tissue. The block of tissue is removed as far as possible *en masse*, and all isolated bone fragments and attached bone "spikes" are included. The clean section of the bone ends and the removal of the fragments is an essential step. The excised tissues are placed in a sterile test-tube or jar and sent to the pathological laboratory. The bed for the subsequent graft is now swabbed out thoroughly with Harrington's solution. The bone ends and the region of the gap—now increased in size—are covered in by a restoration of the fascial and muscular coverings and the skin wound is sutured after undercutting the flaps to allow easy approximation.

This operation is at once an attempt at wound sterilisation, a provocative measure, and a reconstruction of the bed for the future graft. In two to three weeks' time the limb is usually ready for the resumption of physio-therapeutic treatment.

Stage 2.—The bone transplantation is performed in from six to eight weeks' time after the uncomplicated healing of the first stage operation. During this period the usual physical treatment is continued. Ionisation of the wound area is always prescribed in order to obtain the maximum softening of the superficial and deep scars. The details of the technique of the bone graft operation are outside the scope of this article, but my experience of more than 80 bone transplantations for various disabilities has emphasised the superiority of the inlay graft over all other methods. A graft must be long enough to reach several inches above and below the actual gap and should need no additional fixation when accurately wedged into the gutter.

The bacteriological examination of the tissues removed in the first stage is of the greatest importance, whether the findings be negative or positive. If the tissues prove to be sterile, and an uncomplicated healing of the operation wound occurs, the future bone graft can be awaited with confidence. The cultivation of organisms (other than skin germs, e.g.,

Staphylococcus albus, the appearance of which should cause a scrutiny of the operative technique) associated with primary healing of the operation wound affords strong indication that sterilisation of the area of non-union has been achieved.

Two cases in my series illustrate this point. In one, an ununited fracture of the femur of 12 months' duration, with wound scars which had been healed for six months, *B. proteus* was cultivated from the fibrous plug found in the medullary cavity of the lower fragment. Infection of the wound followed. In the second case, non-union of the radius, the same type of organism was isolated, but primary healing occurred and the patient resumed physio-therapeutic treatment in two weeks without any subsequent reaction. In this type of case the second stage should be postponed a little longer than usual, though the waiting period need not exceed three months.

In my opinion the two-stage procedure for bone-graft operations, carried out as described above, has conclusively proved its value, and I regard any procedure less radical than that advocated in the first stage as an inefficient index of the subsequent sterility of the limb and an inadequate preparation for the introduction of the transplant.

SOME ADVANCES IN POLYGRAPHIC TECHNIQUE.

BY H. L. FLINT, M.D. LEEDS,

CAPTAIN, R.A.M.C.; ASSISTANT CARDIOLOGIST IN THE NORTHERN COMMAND; ASSISTANT SURGEON TO THE MANSFIELD HOSPITAL.

THE clinical polygraph has only gradually been making its way into everyday use since its introduction by Sir James Mackenzie many years ago. This instrument in the hands of a few pioneers has given us such valuable information of the mechanism of the heart beat, and has so far unravelled the tangled skein of cardiac irregularities, that it might appear surprising that the clinical polygraph is not now in daily use by all practitioners.

There are, I think, several reasons why this instrument is not as widely used by the profession as the importance of the information it yields would warrant. The chief obstacle may be a difficulty in procuring an instrument; but that is not the only cause, for one occasionally meets a medical man who possesses an ink polygraph but has given up using it. The great objection to the instrument in the past has been the length of time taken not only in assembling the instrument, taking the tracing, and then packing it up again, but in measuring out the tracing and arriving at a correct interpretation. The busy practitioner, much as he would like to use the polygraph, finds he cannot spare the time which is at present necessary if he would acquire the information it will yield.

It is obvious, therefore, that before the polygraph can come into general use the technique must be simplified. I

FIG. 1.—The polygraph in position of use, and the wrist splint.

claim that the following three procedures, which I have adopted, very materially reduce the time, not only in taking the tracing, but in measuring it and arriving at an interpretation: (1) the adoption of a box in which the instrument can be carried about fixed ready for use; (2) the use of a wrist splint; (3) the introduction of a modified slide rule for measuring out the tracing.

Description of Improved Methods.

With the aid of diagrams only a short description of each improvement is necessary.

1. *The new polygraph box.*—Fig. 1 shows the polygraph in the box. The top and front of the box open on hinges; when shut they are fastened by lock and key. All the parts of the instrument, including even the pens, are kept in

position for use. It is only necessary to lift the machine forward into the position shown in the figure and fill the pens before taking a tracing.

2. *The wrist splint.*—In the past a source of annoyance and loss of time in taking a tracing has been the movement of the patient's wrist, resulting in the radial pen being thrown off the paper and spoiling the tracing. This splint, which I have adopted and found very helpful, is also shown in Fig. 1. The wrist is fixed in a position of hyper-extension and the radial artery thrown into prominence. The ordinary wrist-piece is strapped into position round the splint, and the forearm then rests on the operator's knee. The radial pen will write perfectly straight on the paper, and it is possible to keep it quite close to the edge of the paper without any fear of the pen moving off; in fact, the patient can move the forearm without altering the position of the pen. The splint can be applied to either the right or left wrist. Some workers are now using the glycerine tambour elbow-piece for recording the brachial pulse instead of the radial. This, I believe, was first used in Germany and introduced into this country by Dr. T. Lewis. I do not, however, find that it gives such a good tracing as the old wrist-piece.

I do not propose to give an account of the ordinary methods now in use of measuring out a tracing with a pair of compasses. It is only those who use the polygraph who will at once appreciate the enormous saving of time and labour effected by the introduction of my slide rule.

3. *The modified slide rule for measuring tracings.*—This consists of a piece of polished wood with grooved sides to carry a slide. The slide has a window which is partially filled with a thin sheet of celluloid, and a space is left between the celluloid sheet and the ends of the frame of the slide, so that the waves can be marked on the tracing with a pencil. Fig. 2 shows a part of the slide rule, with a tracing

FIG. 2.—The polygraph slide rule.

fixed in position. The tracing is fixed at each end of the slide rule by drawing pins. The slide is then slipped on and moved until the sheet of celluloid lies over the ordinates. The ordinates of both the radial and venous curves are then traced on to the celluloid. These two ordinates are marked by a cross at their upper end. A line 1/10 second to the left of and parallel to the ordinate of the venous tracing is now marked in, c, and gives the position of the beginning of the carotid wave, when the radial ordinate is at the beginning of the rise of any one of the radial beats. Another ordinate, A, 1/5 second to the left of the carotid ordinate, marks the position of the beginning of the auricular wave. An ordinate, v, 2/5 second to the right of the carotid ordinate, gives approximately the summit of the v wave.

Any of these points can immediately be fixed in any particular part of the tracing by moving the slide along until the radial ordinate lies at the beginning of the rise of the corresponding radial pulse. Similarly, any two consecutive radial, carotid, or auricular waves can be marked on the celluloid sheet and the spacing rapidly compared throughout the whole tracing by moving the slide over it. Any other of the many measurements that may be necessary can be made in the same way.

The most convenient method of marking in these ordinates is to use a copying pencil, but if ink is preferred I think the best is Arnold's black waterproof drawing ink. When finished with, the ordinates can easily be erased from the celluloid sheet by a damp cloth. The ordinates can be marked in neatly and rapidly by running the pencil along a thick piece of celluloid cut to the segment of a circle described by the pen. The same arc of celluloid will serve for any tracing if the pens are pushed home into their receiver before taking a tracing.

I hope these improved methods will direct other workers to attempt to simplify still further polygraphic technique. These appliances can be obtained as follows: the polygraph box from Mr. D. Bulmer, 8, Rosebank-road, Woodsley-road, Leeds; the wrist splint from Mr. Arthur Vizard, 46, Great George-street, Leeds; the slide rule from Mr. Fred Raper, 24, Servia-place, Servia-road, Leeds.

ON REPAIR OF THE MALE URETHRA.

By E. D. TELFORD, F.R.C.S. ENG.,

SURGEON, MANCHESTER ROYAL INFIRMARY;

AND

F. G. NORBURY, F.R.F.P.S.,

ASSISTANT RESIDENT SURGICAL OFFICER, MANCHESTER ROYAL INFIRMARY.

THE plight of the man who by injury or disease has suffered the loss of a portion of his urethra is miserable alike from local discomfort and mental distress. Any operation which affords a possible chance of restoring the channel is worth a trial. It is for this reason that we wish to report a case in which we successfully repaired an extensive urethral defect by a method of grafting preputial skin into the gap. Whilst fully realising that no great stress can be laid upon an isolated and possibly fortuitous success, we desire to record the case, since there are, no doubt, instances of men suffering from gunshot injuries of the urethra in which the method may prove of some service. The operation was done over a year ago and the interval is sufficient to render the permanency of the result well-nigh certain. The details of the case are as follows:—

The patient, a strongly built man aged 37, was seized in April, 1917, with a sudden extravasation of urine due to a stricture of old standing. Very extensive incisions were made into the scrotum and lower abdominal wall with perineal drainage of the bladder. Much sloughing ensued, especially about the perineum, but he eventually made a good recovery, the whole of his urine passing by the perineal opening.

On Nov. 14th, 1917, he was admitted to the Manchester Royal Infirmary. Examination showed a small fistulous opening through which the whole of the urine was discharged. This opening was placed immediately in front of the anus and was embedded in much scar tissue.

On Nov. 26th the patient was anaesthetised and placed in the lithotomy position. A median incision 2½ inches long was made, so placed that it embraced the fistulous opening at the hinder end of the incision. Much scar tissue was encountered, but by the aid of a Wheelhouse staff the proximal end of the distal portion of the urethra was identified. This was dug out of scar tissue and freshened by a cross section. The distal end of the proximal segment was then sought. It was found easily, but was difficult to define owing to its being almost flush with the triangular ligament. With both ends thus freed, it was seen that there was no possibility of direct end-to-end union, the gap being 1½ inches in extent.

In order to obtain material to fill in the gap a circumcision was done on a year-old infant with a very long prepuce. This was done by the old forceps method. The portion of skin so obtained was divided vertically and by separating and reflecting the small strip of lining mucosa some increase of the size of the graft was obtained. The graft thus made was rectangular, and consisted for three-quarters of its area of skin and for one-quarter of mucous membrane.

The next stage of the operation was to convert this graft into a tube fixed to the divided ends of the urethra. The graft was first stitched by three sutures to the cut edge of both ends of the urethra on the dorsal surface of the canal. A large silver catheter was then passed and the graft was fixed by sutures at both ends to the cut edges of the urethra on its ventral aspect. A continuous suture, inserted parallel to the catheter, converted the graft into a tube, having skin and mucosa for its inner lining. The sutures were of a lightly chromicised catgut. The soft parts were then united over the graft with some difficulty owing to the scar tissue and the covering layer consisted of little more than skin, which was brought together without drain by sutures of silkworm gut. The metal catheter was left *in situ* and was retained unchanged for eight days, at the end of which time it was removed and no further attempt was made to pass an instrument. On the fourteenth day the patient developed a subacute left-sided epididymitis, due no doubt to the long retention of the catheter. This gave little trouble but was slow in subsiding. The wound healed without incident, no urine having leaked at any time since the operation. The patient passed urine freely after removal of the catheter and continued to do so without difficulty and with no undue frequency.

No further instrumentation was done until March 9th, 1918, 15 weeks after the operation, when sounds were employed to investigate the condition of the urethra. A 9/12 sound was passed without any difficulty. On his discharge from hospital at the end of March a sound passed without any evidence of narrowing of the grafted segment, and three months later a 9/12 sound passed readily.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF SPRUE ASSOCIATED WITH TETANY.

BY P. W. BASSETT-SMITH, C.B., C.M.G., F.R.C.P.,
F.R.C.S., D.T.M. & H.,
SURGEON CAPTAIN, R.N.

THE onset of tetany in association with diseases of the digestive system has been not infrequently noted, but it has not before been recorded in a case of sprue.

The patient, a male, aged 45, contracted the disease on the China Station in 1911-13, probably at Shanghai. He had suffered from many relapses of diarrhoea and sore tongue, but more frequently during the past two years. In July, 1918, he was admitted to the Royal Naval Hospital, Plymouth, for chronic colitis, and the disease was then diagnosed as sprue, the stools being pale, bulky, and fermenting. He was extremely emaciated and debilitated, and weighed 84 lb. On Sept. 19th, 1918, he came under my charge at the Dreadnought Hospital, Greenwich. The condition then was that of a typical case of sprue in its last stage. The temperature was subnormal, pulse 74, respirations 24, and his mental condition was clouded, but he was generally very cheerful. There was intense emaciation, dry skin with increased pigmentation around nipples, scrotum, face, and axillae. The conjunctivae were pearly white, tongue was dry and glazed but no ulceration was present; the abdomen was distended, peristalsis very active and easily stimulated. The stools were semi-solid, pale yellow, abundant, offensive, but not fermenting. The urine showed a trace of albumin. No oedema, petechiae, or sores. The systolic blood pressure was 95 mm., and the pulse of low tension. Examination of the blood showed red cells, 1,480,000, and white cells 3200; polymorphs, 61; lymphocytes, 34; mononuclears, 3; and transitionals, 2 per cent. The blood picture was that of a severe secondary anaemia without nucleated red cells.

Under treatment the patient showed signs of improvement, but on Sept. 23rd he complained of slight cramps in right hand and wrist. These were relieved by warmth. On the morning of the 24th he felt well but for the cramps, and passed a large fermenting stool; at mid-day definite tetany set in, chronic spasm of right hand fingers, wrist, and forearm. The deep reflexes were lost, but the muscles reacted. The condition rapidly became worse, with collapse, intense pain, and sweats, the spasm spreading up the arm and across the chest, with a marked trismus, typical risus sardonicus, and the right leg was slightly affected. The bowels acted involuntarily. Oxygen was administered, an ether injection given subcutaneously, and also a turpentine enema. At 2.30 P.M. the trismus had passed off and he felt much better, but the hand was still clenched. At 3 P.M. he was taking food and felt more comfortable, but was very weak. Calomel was given with Dover's powder, and he was ordered a course of thyroid extract.

There was no return of the tetany, but the general condition did not improve, and on Oct. 3rd slight pyrexia with pulmonary symptoms came on. He died on the 7th quite quietly in the night from heart failure, apparently free from pain.

Post-mortem showed a complete absence of fat in the tissues. The heart (5 oz.) was very small and superficial white patches were present. The intestines contained much soft faecal material; no ulceration was found anywhere, but the walls were very thin, especially those of the lower part of the jejunum and ileum. The mesenteric glands were enlarged. The spleen was small and free from adhesions and weighed 1½ oz. The liver appeared normal, weighing 3 lb. The kidneys were both large, pale, and weighed 4.5 oz. The pancreas appeared normal, and the thyroid was atrophied. The left pleura was adherent throughout and both lungs showed intense oedema, most marked at the bases.

A microscopical examination of the organs was made. The liver showed a slight amount of interlobular cirrhosis. In the kidneys there was some evidence of chronic tubular nephritis, but no infarcts or haemorrhages. The lungs showed haemorrhagic and catarrhal infiltration of localised areas. The pancreas appeared to be normal. Sections of the small intestine showed atrophy of the villi with a small-celled infiltration in the submucosa, and in this layer were a number of stout, oval, and slightly curved, rather large Gram-positive bacilli, but no evidence of yeast-like cells could be found.

The chief interest in the case lies in the severe attack of tetany which came on late in the disease from no apparent cause other than some intestinal irritation; its unilateral character as far as the limbs were concerned, and the severe bilateral trismus; the extreme emaciation of the patient,

making the contracted muscles stand out more prominently even than usual. The rapid action of the subcutaneous injection of ether in relieving the spasm is noteworthy.

PERITONSILLAR ABSCESS FOLLOWED BY OSTEOMYELITIS, NECROSING ENCEPHALITIS, AND MENINGITIS.

BY ANDREW WYLIE, M.D. GLASG.,
SURGEON, CENTRAL LONDON EAR AND THROAT HOSPITAL.

With Report on Pathology by WYATT WINGRAVE, M.D. Durh.

FROM the comparatively trivial degree of its early symptoms, the regrettable delay in evacuating pus, and the extensive lesions revealed by necropsy, this case is of the deepest interest. It is instructive to note the extensive destruction of bone, and that the patient should have suffered so little pain or even discomfort. She continued her work until eight days before death. The thrombosis of the jugular bulb evidently prevented pulmonary sepsis. An early diagnosis of the peritonsillar abscess 16 days before the patient attended hospital, with a free incision and evacuation, would have obviated the serious and fatal complication. The notes of the case are as follows.

Mrs. A. B., age 48, was in good health until April 29th, when she had an attack of tonsillitis and a peritonsillar abscess on the right side; no treatment except a gargle. On May 4th swelling of the left eyeball, slight pain in the throat and back of head; but she did not consult anyone, and continued her daily work. On May 15th the swelling of the left eyeball became worse, and she went to the Western Ophthalmic Hospital. Mr. George Thompson sent her to my clinic, and she was admitted as an in-patient at once.

On admission the patient had pain in the back of the head, neck, and in the cervical region; her speech was not clear. There was a prominence of the left eyeball with ptosis, slight injection in the outer canthus, a dry tongue, and temperature 102° F. No pain over the frontal sinus. Fluctuation was found in the faucal arch due to a peritonsillar abscess of 16 days' duration, which had not been opened or spontaneously evacuated. This abscess was at once freely incised, a large amount of foul pus evacuated, and 25 c.cm. antistreptococcal serum was given.

On May 17th pus was still escaping from the incision. Patient somewhat drowsy, both eyeballs prominent, the movement of the right one limited. Temperature 104°. Pulse 110. 25 c.cm. antistreptococcal serum injected; an intravenous injection of 1 in 1000 solution of perchloride of mercury given a few hours later. On May 18th patient drowsy, restless, sleepless. Both eyeballs swollen and prominent. Two doses of antistreptococcal serum injected. Temperature 104°. Pulse 116. Slight rigor. Abscess explored to ensure thorough drainage. On May 19th patient unconscious. Thick fetid pus still escaping from the abscess cavity. Temperature 102°. Pulse 100. On May 20th patient unconscious, both eyes prominent and fixed. No reaction to light. The house surgeon, Dr. George Lean, reported that ophthalmoscopic examination revealed "choked disc" in the right eye with thrombosis of veins and small haemorrhages. Temperature 102°. Pulse 120. Severe rigor. On May 21st condition much the same. Temperature 102°. Pulse 128. Patient died on May 23rd.

Report of Necropsy by Dr. WYATT WINGRAVE.

On removing the tongue, larynx, and pharynx a sloughing space was found laterally about the level of the soft palate, which travelled backwards in the deep cervical fascia to the prevertebral area. Following the track upward a large packet of green pus was evacuated and traced in the prevertebral muscles to the basi-occipital and basi-sphenoidal bones. Only a thin shell of these remained, their cancellous elements being reduced to a soft green fetid mass extending into ethmoid and orbit.

On removing the skull and dura diffuse purulent meningitis was found involving the whole brain. Over the right temporo-sphenoidal area was an extensive patch of necrosing cortical encephalitis which extended to a depth of 3 cm. All the ventricles were distended by a fetid green pus. Seen from the intracranial aspect the basi-sphenoidal and basi-occipital bones showed complete necrosis. Only their outer walls remained. The pituitary body was reduced to a semi-fluid mass and the adjacent osseous sinuses were full of pus. The jugular bulb, sigmoid, and lateral sinuses were firmly thrombosed.

Films of the pus from all the regions showed the same character—viz., streptococci, staphylococci, mycelia, and coarse forms of *Spirochaeta frutida* with some bacilli of xerosis type (diphtheroid).

The thoracic and abdominal viscera were normal. The right orbit contained green pus which entered by a perforation in the ethmoid, the roof was intact, and the left orbit not involved.

A specimen of green pus, removed on opening the peritonsillar abscess, showed no evidence of recent suppuration. The bacteria were the same as those found at the necropsy. This material was evidently an old pocket of pus from which infection burrowed into the deep cervical fascia in an upward direction causing acute osteomyelitis of the basi-occipital and sphenoidal bones followed by a meningeal infection and necrosing encephalitis. Such conditions strikingly illustrate the powerful tryptolytic action of unevacuated pus even upon living structures hard or soft, an action second only in importance to that of the infecting organisms. The streptococcus was the active pyogen, the spirochaetes being doubtless merely symbiotic saprophytes, yet adding to the destructive powers of the locked-up pus.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

Admission of Pensioners to Civil Hospitals.

A GENERAL meeting of Fellows was held on Tuesday, Jan. 14th, Sir HUMPHRY ROLLESTON, the President, being in the chair, when Mr. H. J. WARING opened a discussion upon the Conditions under which Pensioners of the Army, Navy, and Royal Air Force are Admitted into, and Treated in, Civil Hospitals.

Mr. WARING said that the question of the admission of pensioners into general hospitals for treatment was considered by the council of the Section of Surgery, when it was thought that some agreement should be come to among the hospitals as to the lines of admission and remuneration. With the assistance of Mr. Warren Low and Mr. J. Y. W. MacAlister, circulars were sent round to all the London hospitals with medical schools and a certain number of others. The communication ran:—

1. Does your hospital receive payment from the Ministry of Pensions at the rate of 7s. per head for in-patients and 2s. per head for out-patients?
2. Are the naval, military, and Royal Air Force pensioners admitted as in-patients placed in special wards, in special beds allocated for the purpose or along with ordinary hospital in-patients?
3. Are they placed under members of the hospital medical staff specially appointed for the purpose or are they treated in the ordinary routine practice of the hospital?
4. Are similar pensioners treated as out-patients seen at special clinics for the purpose or are they seen along with the ordinary hospital out-patients?
5. As regards the funds received from the Ministry of Pensions, are they entirely allocated to the general funds of the hospital or are they in part used for payment of the members of the hospital staff who treat the pensioners, and, if so, how are the staff paid?

The replies received could be divided into four classes.

The first class, comprising a comparatively small number, receive these patients and decline to accept any remuneration, because they do not pay any members of the staff for attending to them. Two large London hospitals adopt that principle. There are also two without schools which do so, and one outside London.

The second class comprise those hospitals who receive payment—that is to say, 7s. per day per patient for in-patients, 2s. per attendance for out-patients, and do not pay the staff who attend them. Four large London hospitals take these patients in that way, and one of them proposes, at the end of the year, to discuss the question of what shall be done with the money so received. One very large provincial hospital, which takes 5s. per day for in-patients and 1s. 6d. per attendance for out-patients, does not pay anything to the staff.

The third class take these pensioners at the prices mentioned, and pay 10 per cent. of the total receipts to the members of the hospital staff who attend them. Two London hospitals with schools are on that basis and four provincial hospitals.

In the fourth group the staffs are paid, but in different ways. One receives these patients at 7s. per head and 2s. per attendance respectively, and 20 per cent. is allocated to the medical staff. That, apparently, is the largest payment to staffs of any of the hospitals in this connexion. The hospital is a large one, but without a medical school. Another hospital pays the staff one guinea per attendance per day, giving about four guineas per week to the staff who attend these men as out-patients. (No details as to in-patients.) At one hospital the medical staff are paid £50 per annum for the work, but, apparently, that particular hospital does not receive a large number of these patients. Another hospital which has received the 7s. and 2s. rate does not propose to renew the agreement with the Ministry of Pensions on the present terms.

Arrangements for Treatment and Remuneration.

Considering first the best method of dealing with pensioners in hospitals, Mr. Waring said that the most satisfactory way to him was to allocate a special ward or wards, and to place them under definite members of the medical staff; and as regards out-patients, many of whom were able to do a certain amount of work, to have special clinics in the latter part of the day, so that employed men could attend without interfering with their work. It was difficult to estimate the numbers of these men. Originally it was said that there would probably be 100,000, but the War Office authorities now suggested that that number would not be reached. In the case of a small hospital the matter would be met by allocating special beds in certain wards under the care of particular members of the staff, the out-patient arrangements remaining the same. The value of pensioners for teaching purposes in hospitals with attached medical schools should be borne in mind. Such hospitals should consider how far cases applying for admission were suitable for the education of the medical student. Certain cases were undoubtedly of value for this purpose—e.g., nerve injuries, some bone injuries, but others, such as chronic suppurating bone sinuses, were unsuitable.

In regard to payment, the State had admitted its duty to look after pensioners. They were sent to the hospitals by

the Local Pensions Committee on the recommendation, usually of their medical referee, that they required special treatment. The question therefore arose, Ought the members of the honorary medical staffs to be paid as well as the hospitals? As the State admitted its liability for payment for the treatment, he thought that the staffs ought to be suitably paid. The payment in the majority of cases was apparently 10 per cent. If in a hospital there were 20 beds that would give an income from the pensions authorities of £2000 in the year, of which the medical men who looked after the cases would receive £200. If the allotted beds were not constantly full the income would be correspondingly diminished. If several members of the medical staff looked after these patients the individual emoluments would be very small.

Turning to out-patients, with remuneration at the rate of 2s. per attendance, 10 per cent. of that was less than 2½d. Hospitals which paid this 10 per cent. seemed to think it was right for members of their honorary staff to attend these patients on what to him appeared an extremely minute payment. He did not think any member on the staff ought to be asked to attend under such conditions. There was the further question of whether the hospitals were making anything themselves. In 1917—the last year for which the returns of the King's Fund were available—in one hospital, charging respectively 7s. and 2s., the average cost of each in-patient per week was £3 5s. That hospital was therefore paying its staff for doing something for the State. For out-patients the average cost being 1s. 2d. on a 10 per cent. basis the hospital was making 7½d. out of each attendance. The difference between in-patients and out-patients was therefore striking. At two hospitals £3 5s. was the approximate cost, and one of them had refused to go on at the 7s. rate. In regard to the hospitals with schools the average worked out at £123 4s. per bed per year, which, of course, was considerably more than the State was paying. Taken altogether, the State was not paying sufficient for the treatment of these patients.

Mr. Waring asked if any of the Fellows had proposals to make as to what the State ought to pay if pensioners were to continue to be treated in civil hospitals. The first thing to be done in his view was for hospitals to be paid at least the staffs' out-of-pocket expenses and adequate payment to the medical staff. It would be a fair proportional remuneration to look upon the hospitals as receiving two-thirds of the payment and the staff one-third. The 10 per cent. basis was evidently far too small. Some might prefer the proportions 2 to 1. If his suggestions met with approval he proposed to move a resolution that pensioners should be in special wards, or special beds, under particular members of the staff, that the out-patients should be seen at special clinics, and that, as regards payment, the hospitals should receive two-thirds and the staff one-third of the total amount received from the Pensions Committee.

Criticism of Various Points.

Sir NESTOR TIRARD said that he spoke as a free-lance, being no longer connected with the Army, except in an honorary capacity. One difficulty in treating pensioners in a general hospital arose from the different point of view observed in dealing with pensioners and Army men and with the ordinary type of cases admitted to hospitals. The people likely to be sent to the hospitals by Local Pensions Committees would still carry on some of the sort of Army tradition in regard to qualification for admission to a military hospital. They would in no sense, as a bulk, be suitable for teaching purposes. In dealing with the patients nothing whatever was to be gained except the satisfaction of doing one's duty for men who had been injured in the war. He did not want to minimise that satisfaction, but the profession had to consider if it was prepared to undertake whole-time work in connexion with the Ministry of Pensions, in the same way as they had undertaken such work during the war. There was another difference. In ordinary hospital work patients were visited on definite days settled on by the administration, twice or three times a week, and at other hours when the necessities of patients demanded it. In a military hospital, on the other hand, the principle had been daily attendance during the morning hours. Members of the hospitals had been invited to offer for whole-time work in connexion with the Ministry of Pensions, and by whole-time work was meant daily attendance, whether, in the doctor's opinion, the condition of the patient demanded it or not.

It was the practice in a civil hospital for the resident medical officer to have interim charge of wards. Whether the wards contained pensioners or not this was the only convenient way of working them; and for the members of the staff who have charge of the wards to act as consultants and attend at regular times on definite days. In regard to payment, it would not be necessary to demand daily attendance from the ordinary consulting physicians and surgeons of the London hospitals; their time would be wasted in the majority of cases. For instance, in the medical group it was not necessary for the expert in neurology, shell-shock, dysentery, malaria to attend daily. The work was done by the resident medical officers, who should therefore take a reasonable proportion of the remuneration. If anything came of this proposal for payment, he hoped that the payment would be primarily devoted to the younger men in the profession, those who were living in the hospital and doing the work.

Views of a Hospital Secretary.

Mr. G. Q. ROBERTS (Secretary, St. Thomas's Hospital) said that in the early discussions held between the representatives of the managing committees and of the staffs of four or five of the largest hospitals in London, the decision was reached that everything possible must be done for the men who had suffered in the war. But, at the same time, there must be a recognition, by a payment, of the services rendered by the staff in doing work for which the Government had accepted full responsibility. Personally, he had thoroughly disagreed with the idea of payment by such a ridiculous proportion as the 10 per cent. indicated. Taking the out-patients alone, that represented about 2d. per attendance. A new case was not examined under about 20 minutes. Four fresh cases per hour were about all which could be got through, and 8d. an hour was hardly adequate for the most junior man on the staff. But if, as should be, a man sees also the returned cases, the average per hour goes up. When the 2s. per attendance was mentioned it was never thought that would adequately pay any members of the staff who did the work. With regard to the arrangements made for seeing pensioners there were two important points. Cases likely to be useful for teaching purposes, on which the opinion of an expert was required, should be assessed by the member of the staff seeing the cases, who decided whether he should see the case again for continued treatment. For the remainder, and they were many, in large part functional, a regular evening clinic should suffice. They had been completely snowed under by attempting to treat war pensioners at the ordinary afternoon clinic. The number of new cases usually sent round to out-patient physicians and surgeons was strictly limited. The number of war pensioners referred to hospital who did need the opinion of an experienced man was so great that it unduly handicapped the resident assistant physician or surgeon in selecting cases to send round for the opinion of the staff from among the civilians. Hence the evening clinic under the charge of comparatively young men of experience. Mr. Roberts said that he interpreted the agreement in regard to war patients not that cases sent by the Medical Referee were necessarily received, but they were examined on the opinion of a member of the staff in the same way as civilians were. The members of the staff had been unanimous in saying that as pensioners were occupying beds which, in the ordinary way, would have been occupied by civilians, they would not accept payment for those cases. The governors had therefore felt justified in accepting from the Ministry a payment of 7s. per day, which was the average cost of each in-patient per day at the time the rate was fixed. This year the cost would be found to be considerably higher. Pensioners were hearty eaters, and they cost more to feed than the average civilian patients. The vast majority of the cases attending required massage or electrical treatment, and for these four sessions per week were provided, in addition to the ordinary four sessions taken by the physician and the surgeon. Those cases did just about pay for themselves.

With regard to payment, the money was being kept entirely separate on a twelve months' trial, and an agreed sum was being allotted to the individuals doing the work, including masseurs, those doing medical electrical treatment in the evenings, as well as clerks to keep a complete register. If at the end of the year a balance should remain, its dispersal would only be made after full consultation with the staff.

As a hospital manager he would not set aside special wards for the treatment of war pensioners. These men had been

much spoiled and petted, had been granted little licences and freedom, and were difficult to control afterwards. In ordinary civilian wards they soon fell into the routine discipline of the ward. On an average they had had only 17 in-patients during the year; they could not set aside a special ward for that number. Most of the wards contained 28 patients apiece; the medical cases had to be separated from the surgical, the specially septic cases from the cleaner ones, so that a number of wards would be required if pensioner cases were allocated to separate wards. If special wards were to be provided the Ministry of Pensions would have to make other arrangements. On the present plan the pensioners had the personal direction and decision of members of the staff, who attended to them in precisely the same way as the civilian cases.

Further Discussion.

Sir KENNETH GOADBY said that the first broad question to face was the actual number of wounded in the hospitals at the present time, and the number of those who were potential patients. In his own observation of 10,000 wounded cases, exactly 10 per cent. had re-presented themselves for various treatment. For cases requiring continuous treatment the military hospital was the best that could be devised. The only way to enforce discipline was by knocking off a proportion of the man's pension, a difficult thing to do in a civil hospital. Many of these men would want treatment during the rest of their lives; they were going to be in and out of hospital out-patient departments, with occasional stays as in-patients. He agreed with Sir Nestor Tirard that a large proportion of these would be of no value for teaching purposes. He submitted the advisability of continuing the fixed disability pensions of these men. A man was more likely to work if his pension was continued. He wanted to know how far hospitals would place themselves under the control of the Ministry of Pensions by accepting payment for the treatment of pensioners.

Dr. SYDNEY PHILLIPS said that the question whether hospitals were prepared to take pensioners at all still appeared to be an open question. Sir Nestor Tirard appeared to think that men who came in as pensioners should be required to come under the same regulations as soldiers. But the men had already left the Army, and the inquiry came to the hospitals from the Pensions Committee who had not laid down rules such as obtain in military hospitals. He had not heard that the staffs of London hospitals were being asked to do whole-time work. So far as he had seen, there was no intention on the part of the Pensions Committee to interfere with the treatment of the cases; they left the hospitals to supervise the treatment for which the staffs of those hospitals were responsible. Medical officers in hospitals would as before go as often as they thought right. He saw no reason for not receiving the proposition of the Pensions Committee with favour. It had already been received by St. Thomas's, St. Mary's, and others throughout the year, and, he thought, without very much difficulty. Pensioners would be civilian patients and not even ex-soldiers. The Army in this war consisted to the extent of 99 per cent. of civilian soldiers. They were the same people whom hospital staffs had been attending all along, and they were coming into hospitals every day with the same complaints as they had before. Having been in the Army three or four years, some of them less, did not prevent them having the ordinary diseases and ailments. Of two patients suffering from melaena, one came through the Pensions Committee, the other was seen because it was an emergency. It was impossible for the large hospitals in London to refuse to take pensioners, because a great part of the male population between 25 and 35 years of age who had served in the Army would be in the next ten years patients at ordinary civilian hospitals. It was only a matter of terms. In regard to the objection raised that pensioners were not cases for admission into hospital, he said that the Pensions Committee only asked for cases to be sent in on which the medical staff of the hospital acquiesced as suitable. If there were additions it was to the interest of the hospitals to appeal to the public to improve the hospitals for the requirements of men who had served in the Army. If the hospitals refused to accept these men they would lose the interest of the student for new cases, such as tropical disease, many of which would come in from war areas, and there would be lost an unparalleled field for medical study. The question of payment

was more one for the administration to debate. The Pensions Committee had never made any secret of the fact that they would pay the medical officers. They had said they would pay so much per man to hospitals in which there were resident medical officers, and so much less if there were not resident medical officers, clearly showing they would pay the doctors for the services they rendered and that there were two classes of hospitals, which would not be reckoned as of the same value. They had now said how much they would pay, and it rested with hospitals to allocate it between the staff and the management. Before any hospital could say what they would take they surely must know how much the medical staff was prepared to ask. In future resident medical officers would not be obtained without payment. There would either be unqualified medical officers or paid medical officers resident in hospital.

Discussion of Resolution.

Mr. WARING then read the resolution which he proposed :

That if naval, military, and Royal Air Force pensioners are to continue to be admitted to civil hospitals these conditions should obtain. 1. In-patients should be admitted to special wards or special beds under special members of hospital staff. 2. Out-patients should be seen at special clinics. 3. As regards payment, hospital authorities and medical staff should receive remuneration on the basis of two-thirds to the hospital, one-third to the staff.

He added that after this discussion had been planned it was publicly announced that in future naval and military pensioners would be treated in military hospitals, and he understood that in the main that was being done.

Mr. ROBERTS explained that the instruction was permissive, not compulsory. As far as St. Thomas's was concerned, the pensioners were preferring otherwise, and there had been no diminution in their attendance.

Sir NESTOR TIRARD seconded the resolution, adding that he had seen copies of the circular sent to two of the medical schools, asking, on behalf of the Ministry of Pensions, whether members of the staff were prepared to undertake whole-time duty with them.

The Question of Hospital Accommodation in General.

Dr. LAURISTON SHAW said that to him the question was a larger one than that of dealing with pensioners. If we were not getting the most satisfactory arrangements for those who had been hurt as combatants the reason probably was that we were not having satisfactory arrangements with regard to people who had been crippled in industry. And he hoped the experience now being gained would enable us to see where our difficulties are. Some of the confusion which arose in early negotiations was because we did not clearly make a distinction between the hospitals which had schools and hospitals which had not them. The conditions were utterly different. A strong stand should be taken against cramming beds with cases which could better be treated in hospitals with less elaborate arrangements and equipment than the large hospitals with medical schools attached. It was clear that an enormous increase of hospital accommodation was wanted in this country. This need not be accompanied by corresponding increase in hospital staffs, for a large proportion of hospital patients came in on the recommendation of practitioners, who should continue to treat them in hospital. Patients frequently came solely because their home conditions were not suitable. Hospital accommodation should be classified into that required for serious cases needing special investigation and expert treatment, and cases to be dealt with by a kind of cottage hospital.

Secondly, it was necessary to hold the State to the principle that if it undertook the responsibility for the treatment of the patient it must pay the medical profession for that treatment. It was impossible to say to the Government, "We, as philanthropists, will treat your patients for nothing." We would do so if the philanthropic public would come along and pay for the patients sent into hospital. Any other course would lead to the impoverishment of the profession.

Further Adverse Criticism.

Sir JOHN BLAND-SUTTON said he was hoping to hear of some alternative scheme to that of foisting disabled soldiers on the general hospitals. In London that plan had been already tried for a year. At the commencement of the war, surgeons, he said, saw that their services at a military hospital would not end with the hostilities, but that many of the men would require treatment for months and years. The proper way seemed to be to convert the hospitals for their reception practically into Poor-law infirmaries, places

for incurable and chronic cases. Then a surgical and medical staff could be organised to meet the new conditions who need not be London consultants at all. There must be many men with surgical and medical experience in the Army during the war who would be well able to look after these cases in such institutions. If the practice became general of receiving these cases into the general hospitals, they would soon be filled with chronic and incurable cases. The question of payment was one for the lay bodies of the hospitals, and they could not agree upon it. He suggested putting a motion urging the Pensions Minister to establish his own institutions and rid the hospitals of the incubus. There must be something like 300,000 sick and disabled soldiers to deal with.

Mr. COLES said that at one provincial hospital they had allocated 25 per cent. of the money received from the Pensions Ministry for these cases for the payment of the honorary medical and surgical staff. He thought the time would come when these patients would have to be dealt with in the evening, and the cost would then necessarily be increased. At the present time the rates of 7s. and 2s. did not leave much to be handed over to the staffs.

Major J. ADAMS suggested that the management and teaching staffs of hospitals were rather at variance in their points of view as regards the clinical material of the hospital. The Ministry of Pensions was taking advantage of the bad financial condition of hospitals in offering a subsidy which the management in present circumstances felt tempted to accept. The hospital staffs did not want their beds filled with unprofitable clinical material. A member of the teaching staff of a hospital was at present a servant of that hospital, and if it was right for a hospital to accept payment for patients received, it was between the hospital and the particular member of the staff to agree as to what remuneration he should receive. At St. Thomas's Hospital he had treated a certain number of pensioner patients, but only as if they were ordinary civil cases. He did not go to the hospital more frequently for seeing them, and had not spent extra time in operating upon them. He should, therefore, not like to make a claim for special payment. The proposition that there should be separate wards and separate payment for those wards, he thought, was too difficult for most hospitals to arrange. He agreed that the pecuniary reward to medical officers should in teaching hospitals go to the younger men.

Reply to Points Raised in Discussion.

Mr. WARING, in reply, said he agreed with Sir Nestor Tirard that the medical officers who did the greater part of the work for the patients should receive the emoluments. His main contention was that the medical profession should be paid for the work it did. At St. Bartholomew's there was a special ward with 20 beds and a certain number of patients had to be taken into the general wards in addition. By separate wards he implied that these patients should be definitely placed under certain members of the staff. That would be easier for administration and also easier for the Ministry of Pensions. With regard to discipline, his experience was that if these men were in a general ward they fell in with the usual routine. Evening clinics were, he thought, of great importance in saving of time for pensioner patients. Dr. Shaw's suggestion that more hospital accommodation was required was apparent to all. Modern surgical and medical treatment could not be given under bad surroundings; in the matter of institutional treatment for the non-hospital classes we were one of the most backward countries. As to using the present military hospitals, many of the temporary buildings were constructed only for a few years' use, and some were already beginning to fall down.

The PRESIDENT then put the resolution, clause by clause. Part 1 was lost; Part 2 was carried; Part 3 was carried with the deletion of the word "adequate." On the proposition of Dr. SHAW, seconded by Mr. WARREN LOW, it was decided to send a copy of the resolution to the British Hospitals Association.

SECTION OF SURGERY.

Bone-Grafting.

THE ordinary meeting of the section was held on Jan. 22nd, Sir JOHN BLAND-SUTTON being in the chair.

A paper entitled "Mandibular Bone Grafts," by Major O. W. WALDRON, C.A.M.C., and Captain E. F. RISON, C.A.M.C., illustrated by cases and numerous slides, was read

by Captain RISON, and formed the introduction to a general discussion. The authors state that although bone transplantation is a surgical procedure of long standing, the unexampled opportunity afforded by war injuries has enabled a careful study to be made of its limits and possibilities, especially in cases in which the mandible has been seriously broken up. Within a few days of being wounded most of the cases have arrived at a special centre for treatment, and the large number of cases which had achieved good union testify to the fine results of those who specialise in this work. They consider that the close and continuous coöperation of surgeon and dental surgeon is of prime importance in these cases. In early stages the mouth must be kept as clean as possible, special care being taken in regard to septic pockets and cavities, and in this stage dental splints should be used, the hindering sequestra being from time to time removed, for the prevention of displacement and to ensure due control of the edentulous posterior fragments. Dental splints are usually required for at least two months. In cases where non-union is obvious there should be early attempts at movements of the jaw for the purpose of avoiding atrophy and articular ankylosis. Careful periodic examination of the teeth and the extraction of such as need it is regarded as important. Teeth which are of service in the immobilisation of the parts should be preserved, and there should not be any great pressure on the teeth. Drainage must persist so long as there are any unhealed sinuses. At least six months should elapse since the disappearance of sepsis and inflammation before bone-grafting operations are attempted; and when the ununited fragments are strong and easily controlled, so that the patient is able to masticate with the aid of splints, this period before operation can be extended. The authors believe that quite a number of failures have been attributable to operation having been done too early. Grafts should include both the periosteal and the endosteal surfaces; in fact, all the elements should be comprised—the graft will then most nearly approach the physiological. When open cancellous bone, such as that of the rib, is used replacement is rapid; it is less rapid in grafts cut from face or tibia. The relative osteogenetic activity of transplanted bone varies with the individual case. The authors' work has been done with autogenous bone-grafts. In most instances it is preferable to fix the fragments in good position by means of strong dental splints, and carry out the operative procedure accordingly. The splints should be cemented to the teeth at least a week before the operation to allow the buccal mucous membrane to become habituated to their presence. In 19 of the cases dealt with the anæsthetic employed was rectal oil ether, and the authors think highly of it. Every effort must be made to avoid perforation into the mouth cavity. The edge of the fragments should be trimmed back 2 cm., and intervening cicatricial tissue excised and discarded. Simple instruments have been preferred; it seemed dangerous to use such an implement as an electrically-driven saw in such a confined space. After a good deal of experience they believe bone from the iliac crest gives the best results. The patient should be kept in bed a few days to prevent the formation of a hæmatoma, which might become infective. If a case requires closure of the mouth for months it should be opened at intervals for inspection.

Discussion.

Captain W. E. GALLIE, C.A.M.C., said that some of the old beliefs on this subject had been rudely shaken as a result of experience with war injuries. In the clinic to which he is attached many experiments on dogs had been carried out. When a piece of living bone has been separated from its circulation and implanted elsewhere in the body of the same patient the immediate result is seen to be a coagulation of nerves and vessels, to which the surrounding lymph cannot percolate. This means the death of all the cells in the lacunæ and of most of those in the Haversian canals. The absorption of these structures occupies three to four weeks. On the open mouths of the canals are osteoblasts, which are able to absorb lymph. Ten days after implantation the proliferation of the osteoblasts is well established on both the endosteal and periosteal surfaces, and in a few days new bone formation can be seen on these surfaces. These proliferating osteoblasts attack the dead bone of the graft and quickly cause excavations. Meantime, a re-establishment of the circulation has been taking place as a result of the ingrowth of new blood-vessels into the mouths of the Haversian

canals. This occurs in about two weeks. Ultimately the whole graft is seen to be permeated by vessels and osteoblasts. The union of the graft takes place by the laying down of new bone on the surface. If from the graft endosteal and periosteal surfaces are removed very little osteogenesis takes place from the graft itself. The rapidity with which the changes occur depends on three factors: the size of graft, its density, and the abundance of the osteoblasts on the surface which survive. In some cases months must elapse before replacement can occur. When boiled bone is used for grafts the changes take place at a definitely slower rate. Where there is a gap to be bridged only autogenous grafts promise success; if boiled bone be used here the living elements will slowly disappear. The great point to aim at in grafting, as it is only on the surface that living osteoblasts survive, is to have the largest osteoblast-bearing surface possible; hence the width of the graft should be greater than its thickness. Except in cases where a strong graft is essential tibial bone should not be employed; that of the rib is better, as it is not only more porous but is better supplied with lymph. It is wise to split the graft longitudinally into a number of portions; in that way a large number of osteoblasts will be given the chance of survival. Boiled bone-graft plates have been largely used at this clinic instead of Arbuthnot Lane's metallic plate and have given much satisfaction. Not only is there no likelihood of these getting loose, but at the end of 10 months (as shown in slides) the only evidence of irregularity is a slight fusiform swelling, and even this disappears after a still further interval.

Major MAONAUGHTON DUNN, R.A.M.C., also gave his experiences on the subject in considerable detail, supported by a carefully selected series of sequential slides. He alluded to errors of technique and their results.

Major S. ALWYN SMITH, D.S.O., R.A.M.C., spoke mainly in connexion with operative fixation of carious vertebrae, and stated the kind of cases which should be chosen for it and the technique to be followed.

SECTION OF OTOTOLOGY.

Deafness Associated with the Stigmata of Degeneration.

A MEETING of this section was held on Jan. 17th, Mr. HUGH E. JONES, the President, being in the chair.

The PRESIDENT read a paper entitled "Deafness Associated with the Stigmata of Degeneration." The object of the communication was to show that there is an association between deafness and defects of auricles, the latter being regarded as indices of degenerations or deficiencies of various important neurons. He was not dealing with those gross stigmata of the face and middle ear which result in direct interference with the conduction of sound, but rather with the more subtle signs of defects and even of degeneracy the recognition of the significance of which affected, for good or ill, the reputation of the specialty. Of 210 out-patients in an ear clinic, 64 per cent. showed auricular defects, such as were regarded as associated with degeneracy. Of cases of chronic tympanic catarrh and oto-sclerosis, there was a proportion of 49 defective auricles to 9 good ones, whereas among cases of nerve affection the numbers were 23 to 3. Among accidental affections the proportion was 35 imperfect auricles to 41 good ones. The small numbers which Mr. Jones had been able to deal with definitely showed that there was a preponderance of more or less degenerate auricles in patients who were the subjects of ear disease and deafness. Specially was this true of oto-sclerosis, and that type known as psychical. Of the general public, he was satisfied that defective auricles did not occur in a greater proportion than 1 in 5. On a particular Sunday he noticed that all the choir-boys (who might be deemed to have sound and sensitive ears) had well-formed auricles, as also had the organist and the clergymen, whereas of the 200 worshippers, 1 in 5 had defective auricles. Of 114 eye patients, 90 had good lobules, 12 doubtful ones, and only 11 were actually defective. None of the eye cases complained of deafness. Patients in the ear department disclosed a high proportion with defective external ears.

He quoted the following case in support of his thesis, as it was very rare to find this ear condition uncomplicated with other diseases of the organ. He believed degeneration to be the underlying condition and the predisposing cause of many diseases of the internal and middle ear:

The case was that of a boy, aged 17, who wished to enter the merchant service, but feared that deafness and imperfect eyesight might interfere with his career. He had already consulted five aural surgeons, and had been under varied treatment for a number of years. On the advice of one of the surgeons the lad was taken to a medical electrician, who charged him £150 for treatment which produced no benefit. His father died at the age of 45, his grandfather at 43, but no family history of deafness was obtained. The boy had narrow attached lobules. There was no enlargement of tonsils and no adenoids. The boy was neurotic but intelligent. His ear symptoms might be regarded as caused by pre-senility. His defect was nearly equal in the two ears. There was distinct loss of bone conduction. The boy appeared to be giving the examiner proper attention, but fatigue reaction was not noticed. Ophthalmoscopic examination showed pigmentary degeneration of the peripheral zone of each retina, not, however, of the type of retinitis pigmentosa, as there were no spider-like patches of pigment.

There appeared to be, therefore, in this case correlative degeneration of the auricles, one or more auditory neurons, and the pigment layer of the retina, all of which are epiblastic tissues. Mr. Jones considered that this type is far commoner than it is generally thought to be, and that the factor of degeneration should be taken into account in cases of ear disease which occur in persons exhibiting any of the stigmata of degeneration, however slight. The "type case" quoted presented to the speaker problems which were phylogenetic, ontogenetic, and sociological in character. Treatment must be preventive. F. W. Mott had stated, in one of his lectures, that the neuron, like other cells, nourished itself and depended for its development, life, and functional activity upon a suitable environment, and that it must possess inherent vital energy. In the neuropathic individual, however, in some portions of the nervous system, especially the brain, there might exist communities, systems, or groups of neurons with an inherited low power of storage, hence the energy would rapidly become exhausted and depression of function would be liable to ensue. Mr. Jones did not agree that many who showed defects of the pinna had a criminal tendency or showed defective brain power, but rather, he thought, such defects were associated with localised potential, or actual, degenerations of the auditory nerve tract.

Mr. Jones then proceeded to discuss the subject from the embryological standpoint, and passed on from that to the sociological, declaring that attempts should be made from birth to counteract the tendency; the degenerative factor could only be dealt with on general lines, and nutrition always played a very important part.

A discussion followed, and the PRESIDENT briefly replied.

LIVERPOOL MEDICAL INSTITUTION.—At the annual meeting held on Jan. 16th the following list of officers and members of council was adopted:—

President: W. Thelwall Thomas. Vice-Presidents: K. W. Monarrat, L. Morgan, Hubert Armstrong, and A. Craigmillie. Treasurer: B. Thurston Holland. General Secretary: W. Murray Cairns. Secretary of Ordinary Meetings: T. C. Little-Jones. Secretary of Pathological Meetings: H. Leith Murray. Librarian and Editor of the Journal: R. W. Mackenna. Council: J. H. Abram, F. S. Heaney, Mary B. Lee, C. J. Macalister, Courtenay Yorke, G. C. E. Simpson, F. W. Bailey, J. Martin Beattie, Owen Bowen, Frances Ivens, F. C. Larkin, and E. G. Sheldon. Auditors: Reginald T. Bailey and F. S. Heaney.

The annual report of the council for the year 1918 was presented and adopted, which showed that a programme of meetings similar to that of 1917 was successfully carried through, and that many medical members of the Overseas Forces and of the American Medical Corps had availed themselves of the hospitality of the institution. The fact is noted that two members of the institution, Dr. Bouverie McDonald and Dr. Nathan Raw, have been elected Members of Parliament in the recent Election. The report notes a certain shortage of members owing to the wastage through death and resignation during the war period, but speaks with certainty of the large influx of new members on the return of normal conditions.

EXETER CITY ASYLUM.—At the last meeting of the Exeter City Council it was decided, on the recommendation of the asylum committee, to increase the salary of Dr. G. Norton Bartlett by £125, with an additional £100 per annum next year. The committee alluded to Dr. Bartlett's excellent services and to his devotion in carrying on for three years without an assistant medical officer. The council decided to advertise for an assistant medical officer at a salary of £300 a year, with maintenance and lodging.

Reviews and Notices of Books.

Physical and Occupational Re-education of the Maimed. By Dr. JEAN CAMUS and Others. Authorised translation by Surgeon W. F. CASTLE, R.N. Illustrated. London: Baillière, Tindall, and Cox. 1918. Pp. 195. 5s.

Most of the chapters of this book have been contributed by various Frenchmen and Belgians who, by reason of their special experience, are qualified to write on the subject of their chapters; for the sake of completeness four chapters on the work being done in England are included. The result is a very readable book, although it presents some of the faults liable to occur in a symposium: the length of the chapter does not always correspond with the importance of the subject, and no attempt can be made to reconcile apparently conflicting views of the separate writers. Several of the chapters are very slight, especially those giving an outline of the features of various institutions. Among the most valuable parts of the book are those dealing with agricultural re-education and the work for the blinded. In France it is of the highest importance that agricultural labourers, who have composed 70 per cent. of the Army, should return to the land, where there was a dearth of labour before the war. The writers point out that agriculture has a large number of branches, each of which calls for its specialists. It is cheaper to live in the country, where, too, people are more willing to help one another.

The simplicity of the movements required in agricultural work makes this occupation suitable for men with artificial arms. A patient whose stump is sufficiently long to include the bony insertion of the deltoid muscle has complete control over any prosthesis, and can be made into a useful agricultural worker; even if the stump is useless, M. Boureau holds, there is always work on every large farm for a one-armed man. M. Lindemans, of Port Villez, points out that even the most mutilated soldier can earn a good income from poultry and rabbit breeding and beekeeping. MM. Nové-Josserand and Bourget provide a temporary arm and tool-holder for men to use while being taught farming at the limb-fitting centre; for permanent working hands they suggest that the men, in addition to the routine ring and hook hand, should also be provided with Boureau's swivel ring, Jullien's tool-holder and straps, the use of all of which can be learnt in a few days at the centre. M. Boureau describes a different set of working hands, and deals with the alterations necessary to adapt agricultural and harvest implements and the handles of ploughs and motor tractors for use by farms hands with an artificial arm. The use of motor and electric power to work the land will make up for the shortage of workers due to the war. Dr. Bourrillon is training agricultural mechanics at St. Maurice; after a six months' course the men are able to repair and drive motor tractors. He finds that for this occupation men require their full complement of limbs; slight paralysis is no bar; ankylosis of joints and shortening of limbs resulting from badly united fractures are among the commonest lesions of men who have undertaken this work successfully. Dr. Bourrillon includes agricultural work in the limited number of manual trades he considers can be carried on satisfactorily by a man with an artificial arm. He holds that only work which does not vary much or call for a constant change of tools can be carried on with the help of an artificial limb with a reasonable prospect of success; he considers that the contrivances which the men themselves devise to help in their work are often more useful than artificial limbs, and that it is the duty of medical men to make all such contrivances widely known. At Port Villez Dr. Nyns tells us that of 83 men with amputations of the arm 25 were working in the literary section to qualify for some minor administrative post, and 58 in the workshops. The most intelligent of the men are advised to take up clerical work; of the others, those skilful in the use of their remaining hand are taught printing, photography, drawing, and painting. Men from the country side take up farming and dairy work, while those who are not very intelligent are instructed in French polishing.

In France one half of the blinded soldiers return to farm work and make themselves useful in doing various jobs, such as cleaning out the yard, milking the cows, digging up the beets and potatoes and putting them into heaps, tossing the

hay, &c.; in wet weather and in their spare time they work at brush-making. Sir Arthur Pearson reminds us that the typewriter was originally invented to enable persons blind from infancy to write; practically all the men at St. Dunstan's learn typewriting in order to communicate with others by writing; he finds that the handwriting of a blind man inevitably deteriorates. Some of the men having learnt ordinary typewriting and shorthand-writing, a special typewriter with Braille writing being used, have been placed in situations as shorthand typists, where they are giving entire satisfaction. The employment of the blind teacher, who is not encouraged at ordinary workshops for the blind, has resulted in blinded men learning occupations in a quarter of the time usually supposed to be necessary. Dr. Ferriën calls attention to the work of the Association Valentin Haüy in providing books in Braille; he calls for volunteers to undertake the printing of books for the blind, and advises the use of a small Braille printing press invented by M. Vaughan.

The translator has carried out a useful piece of work well; in one or two places only, by attempting to make too literal a translation, has he rendered the text slightly difficult to follow.

Hygiene of the Eye. By WM. CAMPBELL POSEY, A.B., M.D. London and Philadelphia: J. B. Lippincott Company. 1918. Pp. 344. 18s.

THERE is room for a book on ocular hygiene, and this one fulfils the need satisfactorily, though we think it a pity that it should include several chapters on diseases of the eye which are hardly adapted to a book addressed to the lay public and insufficient as a guide to the general practitioner. Useful information on the prevention of eye diseases and on the proper care of the eyes will be found, however, in a chapter which deals with the protection of the eyes of the new-born; and the same may be said of chapters dealing with the importance of an efficient treatment of squint in young children (more stress might perhaps be laid on this), with refractive errors as corrected by glasses and the proper adjustment of spectacles, with the school curriculum suitable for high myopes and children with serious defects of sight (taken from Bishop Harman's paper on the subject), with the lighting and seating of schools, the protection of the eyes against industrial accidents, and the dangers to sight resulting from an excessive use of tobacco and alcohol. There is also a chapter on the education and employment of the blind, and the problem of preventing the spread of trachoma is touched upon. The illustrations are good.

Surgical Treatment: A Practical Treatise on the Therapy of Surgical Diseases for the Use of Practitioners and Students of Surgery. By JAMES PETER WARBASSE, M.D., formerly Attending Surgeon to the Methodist Episcopal Hospital, Brooklyn, New York. London and Philadelphia: W. B. Saunders Company. In three volumes, with 2400 illustrations. \$30.00. Vol. I. 1918. Pp. 947; 699 figures.

THIS is the first volume of an ambitious work, whose object, as stated in a discursive preface, is "to place in the hands of the surgeon the means for rendering help in every surgical condition under all circumstances." The author hopes, he says, "for the day when all surgeons who are entrusted with the lives of human beings shall be so equipped that they can apply the ideal treatment in all cases which come to their hands." We venture to doubt if such a Master of Surgery will ever exist. Those who have watched the progress of surgery during the last few years, and the increasing difficulty of anything like a complete grasp by any one mind of all that is commonly accepted as "general surgery," know that the years to come will make less and less possible the realisation of the author's dream; and however undesirable the increased tendency to specialisation may be, specialism will remain, and the ambition of a general surgeon, to give an example from the volume before us, to include in his accomplishments a complete acquaintance with diseases of the skin, is for ever doomed to disappointment. Indeed, this chapter of 30 pages on the diseases of the skin is an example of one of the chief defects of a book with such an encyclopædic aim as this: the anxiety lest anything should be omitted produces the result that much that is included is dealt with in a superficial manner.

This first volume deals with general principles of treatment, including aseptics and antiseptics, surgical materials, and anaesthesia; with wounds and operations, inflammations, and surgical infective diseases in general; with tumours; with diseases of the vascular system, diseases and injuries of bones and joints; with muscles, the skin, and nerves. Much of the information given is very up to date, but it is surprising to note, in the sections on wounds, on the blood-vessels, and on nerves, how little has been included of the vast experience gained by surgeons in four and a half years of war. The book is admirably got up and profusely illustrated, but a large proportion of the illustrations, particularly those of operations, are of a somewhat unpractical character.

We cannot avoid the conclusion, drawn from the first completed volume, that this "practical treatise" would have been far more practically useful if it had been less inclusive, nor can we admit that the subject of treatment ought to be so divorced from reference to pathology and symptomatology as has been thought advisable here. The discussion of indications or contra-indications and of prognosis in particular methods of treatment ought to form an important part of a work with such a declared aim—a much more important part than has here been accorded to it.

Gun-Shot Fractures of the Extremities. By JOSEPH A. BLAKE, Lieutenant-Colonel, U.S.M.C. With 40 illustrations. Paris: Masson et Cie. 1918. Pp. 136 + xi. 4 fr.

Colonel Blake has written a very concise and useful little book embodying the latest practice in the treatment of gunshot fractures and wounds of joints of the extremities. Although we may hope that the supply of these injuries has now ceased and that there will be no renewal of it, the book should prove useful for some years to come to those who have occasion to treat such wounds. In his preface Dr. Blake tells us that the work is the outcome of a request from the late Dr. Lewis A. Stimson to write a chapter in a book which he was compiling for the Council of National Defence in America, but Dr. Stimson's sudden death prevented its publication. All the most up-to-date and successful methods, such as those practised by Major Sinclair and those largely involving the use of Thomas's splints and the necessary cutting operations, are well and clearly described.

The section on the treatment of wounds of joints lays down the principles which have generally been found sound in recent British and French experience, and may be taken as a trustworthy guide. We must, however, differ with the author as regards the operative treatment of extensive injuries of the tarsus. If his advice "to resect the entire tarsus, removing the astragalus, but *always leaving the os calcis*" (the italics are ours) be followed, a stump will be left to which it is extremely difficult to fit an artificial foot, and which will be much less useful than that resulting from a Syme's amputation performed well above the malleoli with no redundancy of flap. Experience in limb-fitting hospitals during the last four years has well established this fact.

This little book is very well and clearly illustrated and the print and paper are alike good, and its small size will make it convenient for use.

Röntgen Technic (Diagnostic). By NORMAN C. PRINCE, M.D. Omaha, Nebraska. London: Henry Kimpton. 1918. Pp. 142.

A Manual of X Ray Technic. By ARTHUR C. CHRISTIE, Major, U.S. M.O.R.C. London and Philadelphia: J. B. Lippincott Company. 1918. Pp. 152. 12s. 6d.

THESE two manuals by American authors dealing with the same subject may be considered together. They both aim at the practice of a more or less uniform system of procedure in the examination of the various parts of the body. Major Christie's book is perhaps the more useful one for a beginner, inasmuch as it deals with the elementary principles more fully and has a chapter on X ray therapeutics. Dr. Prince's book is confined to the diagnostic side of the subject and is adapted to the use of those who are more advanced. The various dispositions of the patient and apparatus are shown in an excellent series of reproductions from photographs, full technical details accompanying each. It is not intended to make any comparison in these comments, as any choice between the two would be determined by personal taste and requirements.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 1, 1919.

Medicine and the State.

WE publish this week a paper by Sir HENRY MORRIS, who pleads powerfully and practically for medical unanimity on professional questions and for the display of public spirit among medical men, so that the relations between the State and the doctor can be placed upon a logical basis. Sir HENRY MORRIS's plea is, in essence, for the formation of a medical federation which should be an unattached advisory board at the disposal of the Government on all medical questions, and he urges that this board should be created now, and that it should be thoroughly representative of the medical corporations, the medical societies, and of all ranks of medical practice. He marshals the arguments for the creation of such a body with the force and skill to be expected from him. It would certainly be quite possible, as all readers of THE LANCET will perceive, to dissent from his criticism of those who have criticised the Royal Colleges, while there are passages in this able advancement of professional unanimity to which many interested in public medical service might fairly take exception; but all that is only to say that Sir HENRY MORRIS has been honest in his advocacy and has not hidden his personal views, even while arguing in a wholly impersonal manner. He shows that the medical profession and the public alike have nothing but good to expect from medical unanimity.

This is very different from the spirit exhibited by some medical reformers who seem to see in medical unanimity a step towards the formation of a medical trust, and to anticipate with gusto the day when such a trust will be powerful enough to exact terms from the State. Such would-be reformers are dreamers. This position will never be attained and it is a thoroughly anti-social instinct which desires it. A letter from a well-known physician, who prefers to appear as F.R.C.P., takes a fine and lofty stand in respect of professional ideals and duties, but simultaneously he conceives that those duties should be rendered to the State out of high conviction and not in accordance with a material responsibility towards the State. F.R.C.P. points out correctly that the original efforts of THE LANCET were towards unification of the profession, and expresses his fears that the profession is "in danger of fatally dissolving an organic whole into its component parts" under the stress of increased knowledge and ill-directed specialism. He desires unification, but his view of the relation of the State to medicine is the pessimistic one that the intrusion of the State into medical affairs tends to destroy the individuality and independence of the practitioner and to impair regard for the

patient as an individual. What form of unification is that in which the State is to play no part? The whole population of Great Britain is concerned in the quality of the national medical service and in the legislative and social conditions under which that service is rendered. The medical profession, which ministers to the public in an important, intimate, and ungrudging fashion, has a right to expect that by the legislation now impending the calling of medicine will be placed upon a more secure and dignified basis. Laws cannot, and should not, be made in response to any sentimental claim, but the new Ministry of Health is a recognition, once and for all, of this truth—so well known to those who can think and see—that the health of a nation is its greatest national asset. But when the State enters into relations with medicine for the national good it cannot be regarded as an intruder even in our individualistic calling.

To secure proper relations between medicine and the State the Medical Parliamentary Committee was founded. At the last meeting of this Committee it was announced that Sir WATSON CHEYNE had accepted the chairmanship of the Committee rendered vacant by the resignation of Sir HENRY MORRIS, and at the same time the objects of the Committee were definitely set out. These will be found on p. 190 of this week's issue of THE LANCET, and it will be seen that they largely meet the position considered by Sir HENRY MORRIS as necessary when advocating the creation of a medical federation to act as an advisory committee to express "its matured responsible judgments and its deliberate unified conclusions upon those matters as to which it ought to be both the duty and the privilege of the profession to give counsel and render service for the benefit of the community at large." The Medical Parliamentary Committee, however, possesses objects which require for their justification a completely representative constitution. Such a constitution is as yet wanting, for the Royal Colleges are unrepresented, and the British Medical Association holds aloof. But with its foundations truly laid, its chairman a powerful voice in the opinions of the country, and its executive working steadily and unselfishly towards large ends, the promise of a representative character is a very fair one. If the Medical Parliamentary Committee, having an obvious desire to labour in amity with all men and movements that work for national health, does not succeed in federating medical interests in accord with its proposed scope, there would seem little chance of any similar movement being more fortunate. Elsewhere there is announced the holding of a meeting in London on Sunday next with the view of starting a new professional league in behalf of medicine. At the meeting a resolution will be proposed stating that for divers reasons "the time has arrived when a body representative of the whole profession should be established to watch its interests and be prepared to act in an advisory capacity as occasion demands." Surely such doubling of energies can be avoided and coöperation substituted.

War Pensioners in Civil Hospitals.

EVERY period of transition is apt to present new problems, and the truth of this generalisation has recently been prominently brought to notice in connexion with the treatment of war pensioners. The discussion at a general meeting of the Royal Society of Medicine, of which we publish a report, has done good service in clearly setting forth the present conditions under which war pensioners are admitted into and treated in civil hospitals, thus affording a satisfactory basis for suggestions and recommendations. The answers to a series of inquiries widely circulated showed that no uniform system was adopted by various hospitals. While the Ministry of Pensions had tentatively offered certain terms, the offer had been received by different institutions in a way that might tend to confuse both the charitable public and the Minister of Pensions. An initial informal discussion had already disclosed the need of fuller investigation, but the divergences were only clearly realised when the replies to the inquiry were carefully tabulated. It was then seen that the present system is chaotic. The institutions concerned are still wavering about the need of any special arrangements for war pensioners. Some are so happily situated that they do not desire any remuneration; others hesitate over the allocation of the payments, and have not yet realised whether the amount suggested is intended to provide for the necessary outlay for working expenses independently of any payment to the medical staff, or whether such remuneration had been contemplated in the original proposal.

The evolution of the present system has been fairly simple, the national obligation for the treatment of those incapacitated through the war being recognised from the outset. This provision was primarily supplied by the military hospitals, with medical, surgical, and nursing staff provided from national funds through the War Office. In these hospitals, and in their attached auxiliary hospitals, treatment was continued until it was obvious that nothing further could be done to ensure a return to military service of any description, when the man would appear before a medical board and be discharged from the army. This conversion of a soldier into a pensioner did not necessarily imply that a "cure" had been effected. Occasionally the pensioner might be fit to resume some form of civil occupation on leaving the hospital, but frequently he required further treatment, in the wards, in the out-patient department, or in some special section attached to the hospital. The question by whom such treatment should be supplied soon presented itself, and for a long time it remained uncertain whether pensioners should be provided for by the military authorities, by the Pensions Board, or by the civil hospitals as part of the charitable objects for which they primarily exist. In early days military hospitals were utilised for this purpose of further treatment, the necessary official authority being obtained, while this authority was only granted when the need for treatment was distinctly the outcome of the original war disability for which the pensioner had

left the service. The advantage of this system was that the State had already made provision of equipment and personnel; the disadvantage was that the beds, which were urgently needed for sick and wounded coming from the front, soon became blocked with pensioners. On taking over responsibility for their treatment, the alternatives for the Ministry of Pensions to consider were to create fresh institutions, which would involve delay and great expenditure, or to negotiate with the civil hospitals for the reception of pensioners in lieu of soldiers. The present position formed the subject of discussion, and many interesting facts and opinions were elicited from representatives of hospital committees and of hospital staffs. Many considered that ward treatment would rarely be necessary, that the numbers requiring admission would not justify the provision of special wards, and that discipline might be easier if these men were treated in general wards. Others urged that from the chronic nature of their troubles these patients would not be suitable for teaching or demonstration purposes like others in adjoining beds, and that the fact of payment being made for them might constitute a cause of trouble in a general ward. It will be noted that this question was left open at the end of the discussion while agreement was reached as to the conditions for out-patient treatment and for payment of those concerned therein. Mr. H. J. WARING, who opened the discussion and moved the resolutions, and Sir NESTOR TIRARD, who seconded them, were equally emphatic about the need of special out-patient clinics for pensioners, who cannot be expected to attend at the ordinary hours, and they both urged that some reasonable payment should be made to those who had charge of these clinics. The payment of the staff of a hospital is one of those subjects which ever affords room for differences of opinion. The old arguments made their appearance in due course, and the position was again affirmed that medical men do not pose as philanthropists who scorn payment in their desire to benefit the hospital patient, but consider that the experience and the opportunity of teaching at the hospitals afford adequate compensation. Now, while this is true for the general work of a hospital, it undoubtedly has no bearing on a clinic for pensioners, and if the terms suggested for pensioners as in-patients were correctly stated it would seem to have been contemplated that the medical staff should receive an honorarium. The terms are far higher than those hitherto paid by the military authorities for the maintenance and treatment of sick and wounded soldiers from the front.

It is not so clear that the conditions for admission have been fully agreed upon by the Local Pensions Committees and by the hospital authorities. If special wards or special beds are set aside for the reception of pensioners it may be feared that the recommendation for in-patient treatment may be regarded as equivalent to an order for admission. Ever since hospitals have been established the system of subscribers' letters has been a source of annoyance both to the hospital and to the subscriber. The

hospital naturally desires to sift the cases and to admit only those likely to derive greater benefit than could be afforded by out-patient treatment. The subscriber considers that the recommendation has been wasted if his nominee is not admitted to the wards. To some extent this comparison between pensioners and civil patients may not apply if the Local Pensions Committee act solely on the advice of a medical referee; but even then, as the discussion at the Royal Society of Medicine showed, it was contemplated that all such cases should be sifted in an out-patient or admission room, and the suitability for ward treatment determined in the same way as for ordinary civilians. Under such a system it is highly probable that the number of pensioners found suitable for admission will be extremely small when there is great pressure on space; while it may rise in large institutions with greater elasticity of accommodation, or with greater need of the financial assistance afforded by the Ministry of Pensions. With regard to out-patient clinics there was no doubt that the resolutions of the meeting accurately indicated the feeling of the meeting that separate clinics should be held, and that those conducting them should receive adequate remuneration. Arguments in favour of this course were adduced by nearly every one who took part in the discussion, though Dr. SYDNEY PHILLIPS spoke rather vaguely of there being no essential difference between pensioners and civilians. The qualification for admission to the pensioners' clinic should necessarily be that the need arises directly from some condition resulting from active service, and this condition, in the majority of cases, has already found expression in the recommendation of the invaliding medical board. The Local Pensions Committees doubtless will be guided by these recommendations, and will not send to the hospitals men who, although pensioners, have fresh diseases or ailments which have no relation to their military service. While it hardly seems necessary to advocate that the Pensions Minister should establish his own institutions and thus rid the hospitals of the incubus of treating pensioners, we believe that many of the problems involved can only be adequately dealt with by free discussion, guided by actual experience. For the present it may suffice to say that a public service has been rendered by definite pronouncement in favour of the separation of the pensioner class from the ordinary run of out-patients, and by the realisation that in this work of national importance, for which the nation is prepared to pay, reasonable remuneration should be given to those to whom it is entrusted.

THE POOR-LAW DIETARY.—In view of the intimation by the Ministry of Food that it is no longer desired to enforce even in institutions the restrictions on most unrationed articles, Poor-Law authorities may now revert to the use of the dietary tables in force before the introduction of rationing. It is still obligatory to keep within the scale in the case of rationed articles—butter, meat, sugar, fats, and jam—and the present allowances of milk and cheese are only to be increased with the concurrence of the Local Food Control Committee.

Annotations.

"*Ne quid nlmis.*"

GREAT BRITAIN AND DENMARK.

OFFICERS of the R.A.M.C. recently with the British Military Mission in Denmark speak with enthusiasm of the welcome they received in that country. The Royal Family, officials, and private persons alike went out of their way to show hospitality, not only to the prisoners of war returning from Germany, but also to the staff sent out from England to arrange for their repatriation. For more than four years Denmark has necessarily avoided expressing her traditional admiration and affection for our country, but since the armistice she has felt free to show the warmth of her sympathy. As a consequence our soldiers returning through Denmark have enjoyed almost embarrassing demonstrations of friendship, and "Rule Britannia" is received with enthusiasm in all the restaurants and places of amusement of Copenhagen. Early in January the staff of the Fredericksburg Hospital gave a dinner in honour of the medical members of the British Mission, and this convivial meeting was much enjoyed both by guests and hosts. During the evening Dr. Carl Jørgensen toasted the visitors in a graceful speech. He told how the youths of Denmark from their earliest days were taught to venerate the country of Shakespeare and Byron, of Dickens and Kipling, and how Danish medical men looked with affection to the home of Jenner, Lister, Moynihan, and Mackenzie. He continued: "Five years ago we admired you as the most free people of Europe because you refrained from conscription. Later we had to admire still more because England submitted to the raising of that glorious Army now returning victorious from the most terrible war in history." The English officers made fitting replies to this very flattering address, showing that their relations with Danish colleagues in the prisoners' camps and on social occasions throughout the period of repatriation duty were most cordial. Most medical men in Denmark have a fair knowledge of English, and in conversation many of them expressed the wish that more opportunities for post-graduate work should be offered them in England. It is good to know that through the activity of the Inter-Allied Fellowship of Medicine London can now offer them a good deal of what they seek in this direction. They also mentioned a desire that English medical books and periodicals should be made more easily available for the profession in Denmark. It is to be hoped that something may be done to reciprocate the desire for closer relations with their English confrères which was thus so unmistakably demonstrated by Danish medical men.

THE UTILISATION OF RED CROSS AMBULANCES.

THE disposal of the many thousands of Red Cross ambulance wagons and lorries which will fall into desuetude when peace is signed is a public question of some importance. The scheme put forward by the joint committee of the British Red Cross Society and the Order of St. John of Jerusalem to return the cars to the districts from which they were presented is practical. The plan adopted will, no doubt, be that the more populous districts will have the first claim; but it must be remembered that these are usually in some measure

provided with ambulance wagons, although no doubt imperfectly. On the other hand, the more sparsely populated districts are for the most part ill provided with, and, in fact, in most cases not provided at all with, any means of conveying the injured and sick. There are many parts of the country where no ambulance wagons are available within a radius of a score or more of miles, and it is especially to such districts that help in the direction intended should be given. It should be seen to that every country district should have a means of transport within 20 miles at least of any given point; that would be the area of operation of any one wagon and would extend to a diameter of 40 miles of country. The storage of the wagon and the expenses in connexion with maintenance should be provided by the district, either by a small charge on the rates or by public subscriptions. The driver for these wagons would only occasionally be called upon, and the permanent employment of a driver would not be a public charge, for volunteers would be found in plenty for such work; these volunteers could be organised for spells of duty alternately, a number of names being kept in reserve, so that a driver would be always available. For those that can pay a charge should be made for the use of the ambulance wagon to cover expenses to some extent, while the poor should have the benefit of the transport. The wagons would be most useful to convey persons who have to travel to a large town for a surgical operation, and who have in the meantime to travel by train—a most unsuitable mode of transport in many cases. For cases of infection that have to be conveyed to an infectious diseases hospital many parts of the country are well provided, but, on the other hand, many are not so equipped, and it should be a primary consideration of those dealing with this scheme to see to it that this defect is remedied. The infectious diseases wagon would not, of course, be available for general use, but kept for the special use of conveying cases of infectious ailments. If only one wagon can be had it might be necessary to decide whether the one for infectious diseases should have the primary consideration. The work in connexion with the scheme would be met by the members of the Humanitarian Corps in course of formation, whose purpose is to provide "first aid to those in need," be the nature of that "need" what it may.

THE SYNDROME OF THE FORAMEN LACERUM POSTERIUS.

THE ninth, tenth, and eleventh cranial nerves pierce the dura mater close together and pass through the middle division of the jugular foramen in arithmetical order antero-posteriorly. Immediately in front of the ninth is the inferior petrosal sinus; immediately behind the eleventh is the jugular vein at its commencement. A membranous sheath, sometimes a minute osseous spicule, is all that separates the vessels from the nerves. It should also be noted that the three nerve trunks are in oblique alignment, so that the spinal accessory nerve is external to the vagus and the vagus to the glosso-pharyngeal. Further, the internal carotid artery is but a few millimetres anterior to the jugular foramen. Below the exit from the cranial cavity the three nerves begin to separate almost at once, the eleventh inclining backward over or behind the internal jugular vein and the ninth inclining forwards over the internal carotid, while the vagus

proceeds vertically downwards. Unlikely or even incredible as it might well have appeared before the experiences of the war, a number of cases have now been put on record where a bullet has severed or injured these three cranial nerves at their point of emergence without touching either of the important vessels in their immediate proximity. In such cases the course of the projectile must be approximately from a point behind the mastoid obliquely across the base of the skull to an exit towards the inferior edge of the orbit on the opposite side, or inversely. To Dr. Maurice Vernet,¹ of the Centre d'Oto-rhino-laryngologie at Marseilles, is due the credit of having drawn attention to this syndrome and of having contributed materially to our knowledge both of its clinical entity and of certain interesting points connected with the distribution of the individual nerves concerned. To take the former first; Dr. Vernet has shown that the main features of the syndrome consist subjectively of the following functional triad: (1) nasal regurgitation of liquids (soft palate paralysis); (2) difficulty in deglutition of solids (pharyngeal paralysis); (3) hoarseness (laryngeal paralysis). This does not, of course, exhaust the syndrome, while, objectively, much more can be determined. Taking the nerves individually, Dr. Vernet adduces evidence to show that the motor distribution of the glosso-pharyngeal includes, *inter alia*, the superior constrictor of the pharynx, which lies behind the pharyngeal mucosa visible on the posterior wall of the pharynx when the mouth is open. Accordingly, the result of unilateral paralysis of the superior constrictor is actually visible in a curtain movement of the pharyngeal wall to the unparalysed side at the commencement of deglutition. Functionally the dysphagia consists in difficulty with solids through failure in reduction of the calibre of the passage sufficient to grip the bolus of food. On the afferent side taste disorders of the posterior part of the tongue always coexist with the motor paralysis when the nerve is severely injured, but may be absent in case of superficial injury or slight compression; hence the diagnostic value of the curtain movement of the upper pharynx. As far as the vagus nerve is concerned, the chief part of Dr. Vernet's work on this subject has been directed to showing that it ought to be considered (1) as a nerve irrelevant to all palato-pharyngo-laryngeal motor innervation, the motor fibres of the nerve really deriving from the internal branch of the spinal accessory; (2) as an entirely sensory nerve, even the cardio-inhibitory branches being relegated to the internal branch of the eleventh. There are, in our view, several difficulties in the way of subscribing to the whole of Dr. Vernet's contentions in respect of the vagus, but we may note the clinical features of impairment of the sensory vagus and their part in the complete syndrome of the jugular foramen. They are constituted by: (1) defect of ordinary sensibility in the area of the soft palate, pharynx, larynx, and of the auricular branch—viz., a small area round the external auditory meatus (when the nerve is irritated there is hyperæsthesia or actual neuralgia in the same regions); (2) disorders of salivation, consisting of dryness of the mouth or, if the nerve is irritated, hypersecretion of saliva; (3) coughing fits, not unlike pertussis, in irritation cases; (4) respiratory disturbance in the form chiefly of exertion-dyspnoea or, in inhibition cases, dyspnoea of a pseudo-

¹ Paris Médical, December, 1916; January and March, 1917.

asthmatic type; (5) pulmonary disorders in the form of recurring congestions. As already noticed, Dr. Vernet attributes to the spinal accessory, via its internal branch, the innervation of, *inter alia*, the middle and inferior constrictors of the pharynx, the muscles of the palate and vocal cords. Whatever be the final decision on the interesting questions raised by Dr. Vernet his painstaking work serves to throw into relief the lacunæ in our exact knowledge of the supply and function of these important cranial nerves, and may well be utilised as an appropriate basis for further research.

LOCAL GOVERNMENT BOARD FOOD INSPECTION.

IN an extract, published separately, from the Annual Report of the Medical Officer of the Local Government Board for 1917-18 Dr. A. W. J. MacFadden gives a brief statement as to the work of inspectors of foods during that period. This important branch of the Medical Department has continued the work of supervising the preparation of food materials for the Army which was commenced on behalf of the War Department at the outbreak of the war. During the year the work was considerably increased owing to the decision of the Army Council to provide home-killed meat for the troops in this country, and arrangements were made by the branch for providing the necessary abattoirs, equipment, and staff of meat inspectors for this purpose. The work of the year included the investigation of several outbreaks of bacterial poisoning. In one of these occurring at Brighton Dr. W. G. Savage isolated an organism of a type which has not hitherto been met with in cases of this kind. A full account of this outbreak is to appear in a forthcoming number of the *Journal of Hygiene*. A paragraph on the importation of liquid eggs from China is of interest. Prior to the war it appears that small quantities of this commodity were imported into this country, the bulk of it going to Germany. After the outbreak of war, however, large consignments arrived at certain ports in this country as cargoes in prize ships, and since then large quantities have been imported in the ordinary course of trade. These products occasionally arrive in the form of whole egg mixed, but usually the yolk and albumin are sent separately. The City of London analyst found them to contain boric acid in amounts varying from 1.35 to 2.08 per cent. These results were confirmed by the Government chemist. As is pointed out, when used for the manufacture of cakes and biscuits the amount of boric acid in the finished food as eaten is reduced to about 5 grains per pound. When, however, the eggs became available to the general public for use in milk puddings, pancakes, and so forth, the amount of boric acid consumed by the individual would be considerable. There is also reason for believing that large quantities of these eggs have been used for some time in restaurants. Dr. MacFadden says that—

"the employment of these boricised products for domestic and restaurant use is open to very serious objection,"

and concludes that—

"As the importation of egg-products from abroad will necessarily increase in the future, it would be very advantageous, both from the point of view of health of the consumer and of the economy in shipping space, if arrangements could be made for the product to be shipped as dried eggs instead of in liquid form."

Such a product on the market is, of course, well known, and we have had occasion to report in our

analytical columns that the eggs were so satisfactorily dried as to leave the yolk and albumin uncoagulated. The material, in fact, makes a good omelette, which is about as severe a test as can be tried.

FELLOWSHIP OF MEDICINE: EMERGENCY POST-GRADUATE FACILITIES.

THE Fellowship of Medicine has arranged with different medical schools in London for an emergency post-graduate course of three months for qualified medical men from the R.N., R.A.M.C., and R.A.F., from the Dominions, the United States, and Allies. This course will admit to the general practice of the institutions, clinical instruction in the wards and out-patient departments, lectures and demonstrations, post-mortem demonstrations, laboratory work, &c. Tickets for the whole course, or for one or two months, can now be issued at the rate of £3 10s. for each month. These can be obtained from the Secretary to the Fellowship at 1, Wimpole-street, W.1, the house of the Royal Society of Medicine, to which the Fellowship is kindly given access.

"THE BIRTHPLACE OF GYNÆCOLOGY."

THE Woman's Hospital of the State of New York was founded in 1855, and in a volume of collected papers¹ by members of the surgical board Dr. J. R. Goffe claims for the hospital the distinction of being the first of its kind in the world—namely, founded by women for the exclusive use of women. The hospital owes its origin to the indefatigable labours of the women of New York, to whom Dr. Marion Sims, the father of gynæcology, appealed on behalf of women suffering from gynæcological disorders. But it is nevertheless somewhat of a blow to find no women upon its imposing active staff, with the exception of a junior attending surgeon and the superintendent house officer. From Dr. Goffe's historical sketch we learn that Dr. Sims, after many failures, had devised a means of overcoming the deplorable results of vesico-vaginal fistula which so often followed on long and difficult labours. Forceps were then not in general use to hasten delivery at this stage. Dr. Sims's investigations were carried out at Montgomery, Alabama, where he lived, but, seeking a change of climate on account of his health, he took up his abode in New York, and it was here that the Woman's Hospital was opened in May, 1855, with accommodation for 44 beds. In the following year the executive committee were able to report that 60 patients had been received, 21 of whom had been discharged perfectly cured, and that all except one of the patients still remaining in the hospital were pronounced by the resident surgeon curable. Twelve years later another building was erected with accommodation for 75 patients and staff, and a further enlargement took place in 1877. The present building was ready for occupation in 1906, and its maternity department counts as a model of what such a department should be. During the year 1917 600 confinement cases were under care. Several features are characteristic of the enlightened spirit of this great institution. Interchange of thought among the medical and teaching staff is provided for by a society the object of which is to cultivate social intimacy, maintain interest in the

¹ A Report on the Scientific Work of the Surgical Staff of the Woman's Hospital in the State of New York. Edited by Herman Grad, M.D. New York, 1918.

institution, bring out matters of scientific value in the special line of the hospital's work, and advance the science of gynaecology. Its active membership numbers 60. The Social Service Department assists the work of the staff by instructing patients in their own homes.

DRAFT regulations for nursery schools, dated Dec. 31st, 1918, have just been issued (H.M. Stationery Office, G. 10, price 1d.) by the Board of Education laying down very carefully the standards of physical care required to meet modern hygienic demands.

THE death is announced in Birmingham of Sir James Sawyer, ex-professor of medicine at Queen's College and consulting physician to Queen's Hospital, Birmingham. He was in his seventy-fifth year.

Hunterian lectures are to be delivered at the Royal College of Surgeons of England (Feb. 3rd) by Professor A. J. Walton on the Surgery of the Spinal Cord in Peace and War; (Feb. 5th) by Professor David Ligat on the Significance and Surgical Value of Certain Abdominal Reflexes; and (Feb. 7th) by Professor G. Taylor on Abdominal Injuries of Warfare. The time in each case is 5 P.M.

THE annual dinner of the Hunterian Society will be held at Cannon-street Hotel on Wednesday next, Feb. 5th, at 7 P.M., Dr. Langdon Brown, the President, in the chair. The annual oration will be delivered by Mr. Hugh Lett on Wednesday, Feb. 12th, at 9 P.M., at the house of the Royal Society of Medicine. The subject will be "John Hunter and His Influence on Urinary Surgery." All members of the profession are invited to be present.

THE LANCET, AUGUST 24TH, 1918.

THE Manager of THE LANCET would like to re-purchase or to receive copies of the issue of August 24th for which readers may have no further use, to enable him to replace copies for libraries and institutions in India and the East which were lost at sea owing to enemy action. Such copies should please be addressed to him at 423, Strand, London, W.C. 2.

THE LANCET, VOL. II, 1918: THE INDEX.

THE Index and Title-page to the volume of THE LANCET which was completed with the issue of Dec. 28th, 1918, is now ready, and copies have been supplied gratis to those subscribers who have, up to Jan. 30th, intimated to us their wish to receive them. Other subscribers will be similarly supplied, so long as the stock remains unexhausted, on application to the Manager, THE LANCET Office, 423, Strand, London, W.C. 2. Such applications should be sent in at once.

THE LATE DR. R. A. BUNTINE, M.L.A.—A memorial service was arranged to be held in the City Hall, Pietermaritzburg, Natal, on Sunday, Oct. 13th, in memory of six victims of the torpedoing of the *Galway Castle* on Sept. 10th, among whom were Dr. R. A. Buntine and his elder daughter. The ceremony was, however, postponed until Dec. 15th owing to the influenza epidemic. As a medical man Dr. Buntine had endeared himself to the town and district by his skill and the kindly cheeriness of his temperament. To the poor he gave of his best without stint or hope of reward. His political influence was growing, and he had begun to make his mark in the Union Parliament.

MEDICAL PARLIAMENTARY COMMITTEE.

A MEETING of the Executive Subcommittee of the Medical Parliamentary Committee was held at the College of Ambulance on Jan. 24th, when the resignation of Sir HENRY MORRIS from the chairmanship was announced and the election to the post of Sir W. WATSON CHEYNE was unanimously welcomed. Sir Henry Morris's letter of resignation explained the private grounds upon which he was acting, and expressed his full sympathy with the work and objects of the Committee, whose formation owes so much to his preliminary energies and fostering care. The feeling of the Executive Subcommittee, recorded in a unanimous vote, was that the debt of the Medical Parliamentary Committee to Sir Henry Morris was extremely great.

Sir WATSON CHEYNE, on taking the chair, pointed out how necessary it was that the objects of the Committee should be well defined, as well as its constitution representative, and he indicated very clearly to the meeting the main functions of such a consultative body as he believed would be most valuable. He would regard, he said, the Medical Parliamentary Committee, though one of its objects might be to promote the election of medical men to Parliament, as primarily a body to which the medical men in the House of Commons might turn for detailed information upon medical points as they arose in the course of Parliamentary work, whether in the discussion of Bills in the House or in Committee work. An interesting debate took place, at which it was decided that the following should be adopted as definitely the programme of the Medical Parliamentary Committee:—

Origin and Objects of the Medical Parliamentary Committee.

A large meeting open to the whole medical profession was held at Steinway Hall on Oct. 1st, 1918. The object of those who called this meeting was to give the profession the opportunity of emphasising the fact that it is the duty of medical men to make every endeavour, in the interests of the community, to assist the State in all matters which promote the health of the nation.

It was agreed that for this purpose unity of the profession is essential, and that in order that the considered views of responsible medical men and medical organisations may be adequately placed before the public it is necessary that a greater number of medical men should sit in the House of Commons. Consequently it was decided to take all steps to effect this increase.

With these ends in view a committee was appointed with power to add to its numbers. This Committee is now known as the Medical Parliamentary Committee. Its present composition makes it representative of all types of medical practitioner, and it is hoped that in time the Committee will represent every organisation in the profession.

Thus the main object of the Medical Parliamentary Committee is to endeavour to assist in placing the knowledge and experience of the medical profession at the disposal of the Government and of medical Members of Parliament for the purpose of guiding legislation on preventive and curative medicine in such a way that the health of the community may be safeguarded and placed in the position to which modern science entitles it.

While reserving the right to express opinions on matters affecting the national health, the Committee has no politics, and recognises that individuals must be left quite free to hold and pursue their personal convictions on general political questions.

In order to achieve the objects set out above the Committee proposes: (a) To keep in touch with the Government for the purpose of urging the need for medical representation. (b) To keep in touch with the Party Whips with a view to introducing the names of suitable medical candidates. (c) To keep in touch with the various medical bodies which are pursuing medico-political activities. (d) To keep in touch with medical Members of Parliament. (e) To keep in touch with possible medical candidates. (f) To bring together members of the profession interested in national health legislation and the medical Members of the House of Commons for the exchange of views.

Dr. C. BUTTAR, honorary secretary, pointed out that a meeting of the medical profession had been announced for Sunday next, Feb. 2nd, at Wigmore Hall, having as its object "the constitution of a body representative of the whole profession, to watch its interests, and to be prepared to act in an advisory capacity as occasion demands." It was felt that the creation of such a new body would imply a repetition of work done by the Medical Parliamentary Committee, now developing into a truly democratic institution.

It was decided that, as a means of bringing the profession into closer touch with the new medical Members of Parliament, the Members should be invited to dine, together with the members of the Health Ministry Conference which has been constituted from the Royal Colleges, the Royal Society of Medicine, and the British Medical Association. Accordingly it has been arranged that a dinner will be held at the Café Royal, Regent-street, on Wednesday, Feb. 12th, at 7.30 P.M.

The Right Hon. Christopher Addison, M.P., will be the principal guest, and the dinner will be presided over by the chairman, Sir William Watson Cheyne, M.P.

MATERNITY AND CHILD WELFARE.

Mothers' Pensions in the United States of America.

American public opinion was considerably influenced by the publication in 1909 of the Report of the Royal Commission on the Poor-law in England, with its recommendations as regards outdoor relief to widows, and attention has gradually turned to the question of carrying out the scheme as a public measure. Opinions differ as to the need there is for such help. It was asserted that a large number of children were being put into institutions who, if the means were available, might be better and more economically brought up in their own homes; but as a result of an inquiry made in New York City by Dr. E. T. Devine, and published in 1913, it appeared that only about 4 per cent. of the children placed in institutions in the year of inquiry might have been kept at home with some assistance. It was considered that if a scheme of mothers' pensions were introduced the number of cases of juvenile delinquency would be reduced, and on this subject the statistics compiled by the Chicago School of Civics of cases dealt with at the Juvenile Court in Cook County for the 10 years 1899 to 1909 are instructive. It was found that 34 per cent. of the children came from families lacking the care of one or both parents. The figures quoted in the report of the Bureau of Municipal Research are as follows: Father dead, 14.5 per cent.; mother dead, 9.6 per cent.; both parents dead, 3.7 per cent.; parents separated or divorced, 1.9 per cent.; family deserted by father, 2.0 per cent.; family deserted by mother, 0.8 per cent.; family deserted by both parents, 1.0 per cent.; one or both parents in prison, 0.2 per cent.; one or both parents insane or in institutions, 0.3 per cent. The relatively large number of cases of juvenile delinquency in families in which the father was dead appeared to be due to the fact that the mother frequently tried to be the wage-earner as well as look after the home, with unsatisfactory results to the children.

The object of all the laws for the grant of mothers' pensions is to provide means for preserving ordinary home conditions for dependent children when, on account of death or disability, the usual means of support are wanting; and to secure that the children shall be cared for by their own mothers instead of being placed in institutions or under the care of foster-parents. With the exception of a few States, the laws apply only to mothers, and in a few cases the pensions are expressly limited to widows. Divorced and deserted wives are occasionally included, and in Massachusetts it is left to administrative discretion to deal with these cases. In Michigan alone are unmarried mothers specially included in the law. Need is, without exception, the basis of assistance in all the laws, but in some laws definitions are added, dealing with cases in which the woman owns property, &c. Practically all the laws require the mother to be a fit person, morally and physically, to have care of her children. In seven States it is made a condition that the children live with the mother and that she does not work regularly away from home. In other cases she may obtain, and is encouraged to obtain, part-time employment. The lowest age-limit at which the pension ceases to be allowed on behalf of the child is 14 years. More than half of the laws provide for administration by the Juvenile or County Court. In one case only, Massachusetts, was it made a function of the existing Poor-law officers, under the control of the State Board of Charities. In a few States the payment of mothers' pensions is carried out by the education authorities. Under some laws a new organisation is set up. Periodical supervision is required in all cases, either monthly, quarterly, or half-yearly visits, or general supervision. In the majority of cases the funds for the pension are derived from the county treasury, but in some States they are provided partly out of county funds and partly by means of a State grant.

The methods of fixing the amount of the grant fall in practice into three groups: (1) To allow the mother a monthly sum equal to the difference between her average normal income and the average standard of expenditure, provided that the limits of the law are not exceeded; (2) to allow the mother the flat rate for each child fixed by the law; (3) to allow an amount for each child according to a scale in which the amount is less for each additional child after the first. The last of these methods is the one which prevails in most States. As to administrative working, in Massachusetts it

appears to have been considered that if a new group of workers were appointed to carry out the administration of mothers' pensions the accumulated experience of the already existing Poor-law officers would not be utilised, as, it is stated, cooperation between the two groups was not anticipated. The administration of the new law was therefore, as we have seen, made a function of the existing Poor-law officers under the control of the State Board of Charities. The law specially provides that the pensions are to be non-pauper assistance. This is the only State in which the Poor-law officers are entrusted with the work. Elsewhere the general tendency has been to reduce their activities and to put the administration of mothers' pensions under some other authority. Thus in New York State in 1915 the administration of funds and investigation of cases were to be performed by a specially created body, the Board of Child Welfare, the members of which are generally appointed by the county judges, and in New York City by the mayor. The report of the Bureau of Municipal Research says that "the chief defect is lack of strong central control, such as the Massachusetts law provides for. Apart from this the New York law offers another illustration of American legislative tendency to create new organs of government without adjusting them to earlier and older organs, so that duplicate machinery is created and responsibility thus diffused. Under the New York law widows' relief is not vested solely in the boards of child welfare; the Poor-law officers—the overseers—may likewise grant such relief, and, indeed, they compete in some instances with the newer Child Welfare Board. Finally, the New York Boards of Child Welfare are irresponsible agencies divorced through their method of appointment and retirement from control either of the executive or of the electorate." The need for adequate supervision is emphasised in many reports on the working of the laws.

In the report of the Bureau of Municipal Research it is suggested that a reasonable solution of the problem of employment for mothers is that in most cases the mothers should be expected to supplement the pension allowance by earnings. Exceptions should be made where there is a large family of young children and where the woman is not strong. Certain kinds of occupation should be prohibited. One of the most practical forms of work appears to be office cleaning, as the hours can generally be arranged to meet household needs. The wages, however, are very low and the work often arduous.

In the instructions to the Poor-law officers (overseers of the poor) issued by the State Board of Charity of Massachusetts in November, 1913, it is said that "there are undoubtedly relatives or other reliable persons living with many of these families who can give the dependant children proper attention during the mother's absence. To insist that the mother shall not work regardless of home conditions would tend to discourage that desire for thrift and independence which is an essential element in society. The policy should be stimulative and constructive rather than destructive." The general practice of the State is to limit the work to three days a week.

Effects of the mothers' pension system.—The danger that mothers' pensions may lead to the weakening of family obligation and the lessening of family responsibility is fully recognised. Another danger referred to in the Report of the Bureau of Municipal Research and elsewhere is that by the extension of the system of public subsidies employers of labour may be led to underpay their workers, relying on social legislation to make up the deficiency. The direct results of the pensions, inadequate though they are in many cases, on the economic position of the families concerned, is generally considered to be satisfactory. The chief probation officer in Cook County says that "for the children of mothers with right motives and willingness to accept and follow friendly and intelligent advice the system has been of great benefit." He points out that this form of assistance is not successful with mothers who, although they meet the requirements of the law, are not capable of using the money to the best advantage, or who are unwilling to accept advice on the subject.

With regard to the principle upon which mothers' pensions are based, the two chief theories held are (1) that the pensions are compensation for services rendered to the State, and (2) that they are a new form of public relief. The report of the Massachusetts State Commission says that

the terms "pensions," "indemnity," and "compensation" are irrelevant, but the term "subsidy" implies that a condition exists which, aided, will result in positive good to the State. "Subsidy makes it possible that children should stay with their worthy mothers in the most normal condition still possible when a father has been removed by death. The present system of aid is primarily for the worthy poor. What a good mother can do for her own children no other mother can do, and in her task she deserves all honourable aid." Alternative measures suggested include a scheme of social insurance, which would embrace the whole community; measures for preventing industrial accidents and reducing preventable disease; and general social improvements. About 45 per cent. of the fathers of families receiving pensions in New York City had died of tuberculosis. In Massachusetts in the year ending Nov. 30th, 1916, 31 per cent. of the fathers had died of tuberculosis, 21 per cent. of pneumonia, and 14 per cent. of the deaths were due to industrial accidents; in many cases tuberculosis appeared to have been contracted in the course of the man's employment.

International Congress and Baby Weeks.

The outstanding feature of the 1919 Baby Week celebrations, which are again planned for the first week in July, is to be a series of national conferences on infant welfare, at which the chief points for discussion will be (1) ante-natal and neo-natal casualties, their prevalence, causes, and prevention; and (2) the best non-medical means of combating infant mortality and morbidity. The National Association for the Prevention of Infant Mortality and the National Baby Week Council are co-operating in the preparations for these conferences, and arrangements are being made for the holding of similar conferences and Baby Week celebrations in every Allied and neutral country throughout the world next year, at which the same subjects will be discussed. Following on this an International Congress will take place in London, at which the findings of the various national conferences will be considered, leading, it is hoped, to much light being thrown on these important subjects.

Saving Child Life in U.S.A.

According to authorities in the United States, the death-rate of babies under one year is dependent upon a number of individual and social causes, some of which are: congenital and hereditary defects of debility; hereditary tendencies connected with syphilis, drunkenness, degradation, or degeneration of parents; inexperience and negligence of parents, voluntary or enforced by industrial conditions, including improper feeding of infants; employment of women in factories during pregnancy and soon after childbirth; poverty as a whole, with all that it implies, including improper housing, congestion of working men's quarters, especially overcrowding of their living-rooms; a too high birth-rate.

An infant mortality survey by the New York Milk Committee has been made public, which shows that the efforts of the various agencies engaged in infant welfare work, as well as the work of the New York Milk Committee, have been effective in reducing the infant death-rate in that city. The survey covers the calendar year of 1917, for which the death-rate was 88.8 per 1000 living births. In 1907 the rate was 144.

The report of the committee also contains figures from 163 of the largest cities, showing with one exception decreases in the death-rate, among the most frequent causes of babies' deaths being gastro-intestinal or diarrhoeal troubles. In New York City the infant death-rate from diarrhoeal diseases has steadily decreased from 44.4 in 1907 per 1000 children born to 19.1 in 1917. Not only have thousands of infants' lives been saved, but the health of children of all ages has been greatly improved of late. This is to a large extent ascribed to the creation in 1908 by the New York Health Department of the Bureau of Child Hygiene, the first of its kind to be established in the world, which was soon imitated by other American cities. This bureau supervises and educates the midwives; provides instruction to mothers and expectant mothers through a large number of "baby health stations"; teaches young girls their future maternal duties; takes care of the nurseries and kindergartens with their children of pre-school age; looks after the health conditions of the school children by means of the medical inspection of the schools and the help of the

nurses, who examine the children in the schools and in their homes; and, finally, ensures with increasing success that only adolescents who are physically fit are allowed to work when they attain the legal working age.

The health committee of the Mayor of New York's Committee on National Defence is making a physical examination of all children under 5 years of age in Greater New York. Dr. S. Josephine Baker is directing the work, and she has established clinics in all boroughs. More than 1000 nurses, welfare and social workers, have volunteered their services, together with 300 physicians, who are working at least two days a week free of charge. There are more than 100 clinics for this purpose in Manhattan alone, the principal borough of New York. During the week beginning July 15th some 3000 babies were examined. There is a total of over 600,000 children to be examined. And as the best time to combat and to prevent tuberculosis is in childhood, open-air classes for certain selected pupils have been provided and have been a great help in the case of children who are ill, anæmic, or predisposed to disease. The first open-air school was started at Coney Island, near New York, in 1904, and there are now 102 schools. The following types of children are admitted to these open-air classes: (1) children exposed to tuberculosis at home, or in whose family there has been a recent death from this disease; (2) children who have had tuberculosis, which is now arrested or cured; (3) children suffering from malnutrition; (4) children who become tired easily or show languor or fatigue before the end of the day, and on this account are unable to carry on their class-work; (5) children suffering from nervous disease except chorea; (6) children who are frequently absent because of colds, bronchitis, &c.; (7) children suffering from cardiac disease who are recommended by their private physician as being proper cases for these classes. This classification provides for the tubercular, pre-tubercular, and physically subnormal children who may be benefited by this open-air life. Dr. L. Marcus, the supervising inspector of the classes, says that the following results of open-air class-work have so far been observed:—Physically subnormal children improve in their mental and physical condition and their nutrition and weight improve, the gain being in most instances permanent; arrested cases of tuberculosis have no relapses; the nervous system is restored to a normal condition; cardiac cases kept under proper medical supervision improve markedly; capacity for work is increased and brought to at least a normal average; absence from school on account of illness is greatly reduced; proper diet is followed and food properly prepared; good habits are established; hygienic rules are observed; and children learn how to do the right things at the right time.

This is an outline of the vast work done in the United States to reduce infant mortality and to ameliorate the conditions of child life. New York may be said to have led the way in its excellent and efficient scheme for the starting, supervision, and general conduct of day nurseries.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Milk-supply of Dublin.

A FEW months ago the Earl of Granard, chairman of the Food Control Committee for Ireland, appointed a committee to inquire into the present milk-supply in the city of Dublin, and to report on the best methods of obtaining additional supplies from the country, and placing the supply of milk generally on a more satisfactory basis. The committee had as chairman the Lord Mayor of Dublin, and it contained two representatives of the public health committee of the city, two members of the Local Government Board, a number of persons interested in the milk trade, and certain others with special knowledge. A unanimous report has now been presented, certain reservations on minor points being noted by a few members of the committee. It was found impossible to discriminate accurately between the city and the immediate suburbs, and the report in reality deals with the conditions affecting an urban population of about 400,000. About two-thirds of the total supply comes from producers within or on the confines of the city, while

only one-third comes from country districts. Apart from the small quantity of milk of cows privately owned, the milk-supply of Dublin during the period of investigation would afford about 240 pints per head per week. The committee point out that the supply is inequitably distributed and that some of the milk arrives sour from the country. The milk vendors, in fact, were able to inform the committee that they would have required about 1000 gallons additional per day to meet the needs of their regular customers. There was, therefore, a definite shortage—most acutely felt, as might be expected, in the poorer quarters. The actual shortage the committee calculate at 2000 gallons a day. This additional supply could be obtained from the country were it not that there is also a definite shortage of railway milk churns. In regard to this matter the committee make a grave charge against the Ministry of Food. A written request for a priority certificate for the supply of 2000 churns had been forwarded to the Ministry on Nov. 16th, but up to Dec. 12th no contracts had been placed, and there was no prospect of any churns being available before the end of January, if then. The actual shortage of milk-cans seems to be due in large measure to the slovenly methods of the carrying companies, who make no charge, and take no responsibility for "empties."

The committee discussed the relative advantages and disadvantages of the system of city cowkeeping, under which two-thirds of the milk-supply of Dublin is provided. The system is, of course, closely bound up with the large brewing and distilling industries of the city, which provide cheap feeding-stuffs. Apart from this, its chief advantages are that it permits two daily deliveries of fresh milk and the dairies and cowhouses are subject to inspection by the city health officials. The quality of the milk distributed in Dublin has been a subject of much public discussion during the past few years, and in view of the seriousness of the allegations to producers as well as the public, the committee consider that the matter should be investigated by a competent authority, as they are not in a position to say whether the statements are founded on fact.

Among other suggestions, the committee recommend the temporary retention of the existing control of the export of milk cows; retaining fixed prices for the raw materials of production; the enlistment of the services of voluntary agencies so as to reduce the ultimate price of milk in the poorer-class districts by the reduction of existing charges for distribution; and, finally, the establishment of milk-drying factories at suitable centres of production.

The Strike in Belfast.

When the men at the shipyards struck and ordered out the workers at the city tramways, gas, and electric stations, in order to paralyse all parts of the city of Belfast, they showed a disregard for human suffering which it is hard for medical men to pardon. The hospitals suffered terribly by loss of power, heat, and cooking, especially from the interference with the gas, and the fate of many patients may have been adversely determined.

The Belfast Hospital for Skin Diseases.

At the annual meeting of the supporters of the Belfast Hospital for Skin Diseases, held on Jan. 24th, it was reported that in the three months following on Oct. 1st, 1918, there were admitted 270 patients, bringing the total since the hospital was established up to 51,059. Financially, there was a sum close on £250 on the credit side, which enabled the committee to invest £188 18s. 6d. in purchasing £200 War Loan stock.

A MASS meeting of the medical profession will be held at the Wigmore Hall, Wigmore-street, W., on Sunday, Feb. 2nd, at 4 P.M., under the chairmanship of Professor William Russell, formerly President of the Royal College of Physicians of Edinburgh. The following resolutions will be proposed:—

1. In view of prospective legislation and the proposed establishment of a Ministry of Health, and having regard to the experience of the medical profession at the time of the passing of the National Insurance Act, the time has arrived when a body representative of the whole profession should be established, to watch its interests and be prepared to act in an advisory capacity as occasion demands.

2. That a provisional committee be now formed with the object of securing the election of such a body.

All medical practitioners are invited. Admission on presentation of visiting card.

The War and After.

MEDICAL MOBILISATION AND DEMOBILISATION: THE WORK OF THE CENTRAL MEDICAL WAR COMMITTEE.

It is now recorded that the Central Medical War Committee owed its formal inception in 1915 to the instruction of the Annual Representative Meeting of the British Medical Association held in that year, while each successive Military Service Act as it reached the Statute Book gave the Committee an increasing orbit of activities with correspondingly increased status. The third Act, passed in April, 1918, appointed the Committee, in fact, the medical tribunal for England and Wales. As in the months that followed the demand of the Army authorities for medical men became hotter and hotter, the Committee's work became highly arduous and difficult in reconciling the demands of the military authorities with the needs of the civilian population and the rightful claims of the medical men themselves. The fastigium was reached on Nov. 11th, when, with the signing of the armistice, the statutory duties of the Central Medical War Committee as a medical tribunal came to a sudden cessation along with those of all other recruiting tribunals. The Ministry of National Service was then nominated by the Government as the department to demobilise civilian doctors included in any branch of the Services, and an Inter-Departmental Committee was appointed under the chairmanship of Sir James Galloway, including two invited representatives of the Central Medical War Committee. But the Committee's share in medical lysis has been a much greater one than this relation suggests, for with commendable prevision the problems of demobilisation had been carefully considered and a complete scheme of priority drawn up in order to ensure the return of medical officers to civilian life upon an orderly and equitable basis. This scheme, which we published in THE LANCET of Jan. 11th (p. 84), it was, in fact, which the Ministry of National Service adopted, although the final word in a particular case rests with the Minister and not with the Committee, the status of which in the matter is purely advisory and consultative. During the whole period of mobilisation and demobilisation the Central Medical War Committee has played an honourable part, and its help was specially valuable in the very acute stages before and after the cessation of hostilities.

CASUALTIES AMONG THE SONS OF MEDICAL MEN.

The following additional casualties among the sons of medical men are reported:—

Lieut. A. Haydon, Royal Engineers, died in London of pneumonia, youngest son of the late Dr. E. Haydon.
Capt. R. M. R. Davison, North Staffordshire Regt., attached Leicestershire Regt., died of wounds after repatriation from Germany, youngest son of Dr. R. T. Davison, of New Malden, Surrey.

FOREIGN DECORATIONS.

The King of the Belgians has conferred the Cross of Chevalier of the Order of the Crown upon the following medical men in recognition of their services to the Belgian civil population in the Yser district, notably on the occasion of an epidemic of typhoid fever in 1914-15, while working with the Friends Ambulance Unit:—

Mr. G. E. Fox; Dr. S. A. Henry; Dr. W. Smerdon; Dr. T. T. Thomson; Mr. J. R. Rees; Mr. H. C. Manning.

French.

Croix de Guerre.—Surg.-Lt. N. H. Smith, R.N.

Japanese.

Order of the Sacred Treasure, First Class.—Surg.-Vice-Adml. Sir W. H. Norman, K.C.B.

THE Royal Sanitary Institute has arranged a Conference on "Post War Developments relating to Public Health" to be held on March 13th, 14th, and 15th, at which the following subjects will be brought forward for discussion: City Hygiene in Relation to Employment; Housing for City Clerks and Similar Workers; Public Health Aspect of Tuberculosis; Public Health Work and Propaganda; Welfare Work in Factories; Child Welfare Work.

OBITUARY OF THE WAR.

HARRY GEORGE MELVILLE, M.D., F.R.C.S. EDIN., C.I.E.,

COLONEL, INDIAN MEDICAL SERVICE; PROFESSOR OF MATERIA MEDICA, LAHORE COLLEGE.

Colonel H. G. Melville, who died suddenly at Bagdad on Dec. 7th, at the age of 49 years, was second son of the late Francis Suther Melville, D.O.S. of Edinburgh. Educated at the Edinburgh Collegiate School and the University of Edinburgh, where he had a distinguished career, he acted as demonstrator in anatomy under the late Professor Sir William Turner, was the first president of the Edinburgh University Union, and one of the three presidents of his year of the Students' Representative Council. He graduated M.B., C.M. at Edinburgh in 1890, and after resident

positions at the Edinburgh Royal Infirmary, joined the Indian Medical Service in 1892 and became medical officer of the 5th Punjab Cavalry (now the 25th Cavalry) in 1896. He served in the Waziristan Expedition of 1894-95 and received a medal and clasp; in the Mohmand Campaign of 1897 and received a medal and two clasps; and in Tirah in 1897-98. In 1901 he was appointed a professor in Lahore Medical College. He held several chairs there, at the time of his death being professor

of materia medica and becoming one of the most sought physicians of Northern India. A recent principal of the College at Lahore writes of the trust and affection in which he was held by the Indian students who passed through his hands. In 1911 he was appointed by the Punjab University to represent it at the Quincentenary Celebration of St. Andrews University.

In 1916 he was appointed consulting physician to the Indian Expeditionary Force in Mesopotamia, and later to the Mesopotamian Expeditionary Force, where he worked with much success to reduce the toll of disease among the forces there. Based at Basra, he paid periodical visits to depôts on the Tigris and Euphrates. After a brief respite from his labours he returned to Basra in September, 1918, and a month or so later was appointed to Bagdad, where he died suddenly from arterio-sclerosis. He was mentioned in despatches in April, 1918, and later was awarded a C.I.E. Already master of several native languages, it was characteristic of him that after his appointment to Mesopotamia he set himself diligently to study Arabic.

Colonel Melville married in 1903 Isobel, youngest daughter of the late Alexander Lawson, of Burnturk, Fife, and leaves a widow and one daughter.

Captain **WILLIAM FRANKLIN LUTON, C.A.M.C.**, who died of pneumonia at the 2nd Southern General Hospital, Bristol, on Oct. 20th, being admitted there from the vessel on which he had been transport officer, was 29 years of age. Not having been a member of the Canadian Expeditionary Force in England, his official documents are not in the possession of the Canadian authorities in London. It is known, however, that he joined the active Militia in Canada in 1915 at Victoria, British Columbia.

WE announced in THE LANCET of Jan. 4th the death of Captain **A. J. Milne, M.B., S.A.M.C.** Mr. James W. Milne writes to inform us that he has definite information to the effect that Captain Arthur James Milne, S.A.M.C., died at Fort Johnstone, Rhodesia, on Dec. 7th. He has received South African letters, dated Dec. 8th and 15th, from the family of Captain Arthur John Milne, S.A.M.C., who is his brother, and who, he concludes, is living. We regret the error, which was also made, Mr. Milne tells us, by the South African Records Office at Pretoria.

JOSEPH VINCENT DUFFY, L.R.C.P. EDIN.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain J. V. Duffy, who died in East Africa of influenza on Dec. 7th last, aged 27 years, was second son of Francis Duffy, of Jesmond, Newcastle-on-Tyne. Educated at St. Joseph's College, Dumfries, where he was a scholar and prizeman, and Glasgow University, he obtained in 1914 the triple diploma of the Royal Colleges of Physicians and Surgeons, Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. After qualifying he first went into practice with Mr. A. M. G. Walker, at Hepburn-on-Tyne, surrendering this work in order to join the Royal Army Medical Corps. He had served in all the principal theatres of war—France, Gallipoli, India, and East Africa—before succumbing to the common enemy of mankind.

WILLIAM ROBERT O'KEEFFE, L. & L.M.R.C.P. & S. IREL.,
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain W. R. O'Keeffe, who died suddenly of septicæmia at Beirut, Palestine, on Nov. 21st, was son of Mr. C. H. O'Keeffe, manager of the Provincial Bank, Waterford, and of Mrs. O'Keeffe, of Ballsbridge, Dublin, grandson of Dr. W. M. O'Keeffe, of Mallow, and nephew of Major-General Sir M. W. O'Keeffe, K.C.M.G., M.D., M.Ch. Educated at Clonmel Grammar School, Kilkenny College, and University College, Cork, he qualified in 1912, and was afterwards assistant to Dr. J. S. Mather, of Bristol, and Dr. White, of Stretford-le-Hope, eventually going into practice in Sheffield. He was an all-round athlete, being a member of the first fifteen at University College, Cork, when that team won the Rugby Football Dudley Cup; he was also a fine swimmer. He leaves a widow and two children.

HENRY RUTHVEN LAWRENCE, M.D., F.R.C.S. EDIN.,

MILITARY CROSS,
CAPTAIN, SOUTH AFRICAN MEDICAL CORPS.

Captain H. R. Lawrence, who recently died in a casualty clearing station in France from pneumonia following influenza, was son of the late Dr. T. Lawrence, of George, Cape Colony. Educated at St. Andrew's College, Grahamstown, South Africa, he graduated at Edinburgh University and took his F.R.C.S. Edin. in 1912. He then proceeded to Cape Town and started practice at Newlands. He received a commission in the Union Defence Force and was called up for service within a day or two after the outbreak of war. He served in German South-West Africa until this campaign was successfully closed, and immediately volunteered for service overseas, and came to England with the first draft of the South African Expeditionary Force in September, 1915. He served for a time in England and in France with No. 1 South African General Hospital, and was then transferred to No. 1 South African Field Ambulance. Shortly afterwards he was appointed regimental medical officer to the 4th South African Infantry, and with this regiment he went through

many of the fiercest battles in 1917-18. He was awarded the Military Cross for bravery in action during the last month of hostilities.

Captain Lawrence was widely known in South Africa, both as a skilful and successful practitioner and as an athlete. He was a sportsman and yachtsman, and rowed for his University as a student.

Captain C. R. LISTER, M.C., A.A.M.C., who died from influenza on Nov. 21st, was educated at Hawthorn College, Melbourne, where he was a member of the cricket and football teams, and proceeded to the Melbourne University in 1909. During his first year he attended Trinity College, though not in residence there, and graduated with honours in March, 1914. He obtained his "University Blue" by becoming a member of the University tennis team during his third year, and was a member of the Victorian team in the inter-State matches of 1912. After graduation in 1914 he was resident medical officer at the Melbourne Hospital from March, 1914, to 1915, and was out-patient surgeon at the Melbourne Hospital from 1915 until 1918. He was also appointed demonstrator in anatomy at the Melbourne University in 1915, and was subsequently appointed Stewart lecturer in anatomy, holding this appointment for three years, up to the time of his embarkation for active service in 1918. In 1915 he was appointed resident tutor in surgery at Trinity College, and at the end of that year volunteered for active service, but owing to the difficulty at that time of securing a suitable successor as demonstrator in the anatomy school the University authorities were unable to release him. During the long vacation of 1915-16 he served as a medical officer on a troopship between Australia and Egypt. In 1917 he obtained the degree of Master of Surgery of the University of Melbourne. At the end of that year when the University authorities were able to release him, he enlisted in December, and arrived in England in July, 1918. After two months' duty in England he proceeded overseas to France, and died at No. 14 General Hospital at Wimereux from influenza on Nov. 21st. He married Miss Meryl Waxman, the daughter of C. R. Waxman, of Melbourne, who is well known in tennis circles, and leaves his widow with one child.

MENTIONED IN DESPATCHES.

In a despatch received from the Commander-in-Chief, British Salonika Force, dated Dec. 1st, 1918, the following reference to the Medical Services is included:—

In this unhealthy climate the efficient administration of the Medical Services is naturally of extreme importance, and in this respect a very high standard of efficiency has been attained. In an army saturated with malaria, and passing through a severe outbreak of influenza, heavy calls were constantly made on the strength and devotion to duty of the Royal Army Medical Corps, of whose work I cannot speak too highly. I am much indebted to Major-General M. P. Holt, K.C.M.G., O.B.E., D.S.O., and his subordinates for the admirable manner in which their duties have been performed.

The names of the following medical officers have been received from the Commander-in-Chief of the Egyptian Expeditionary Force as worthy of mention for their services during the period from March 16th to Sept. 18th, 1918:—

Staff.—Temp. Maj. (acting Lt.-Col.) J. J. Abraham, D.S.O., R.A.M.C.; Temp. Capt. (acting Lt.-Col.) W. Angus, R.A.M.C.; Capt. J. Chalmers, R.A.M.C. (T.F.); Col. E. J. & Evatt, D.S.O., R.A.M.C. (T.F.); Lt.-Col. (acting Col.) C. Garner, C.B.E.; Capt. and Bt. Maj. (temp. Maj.) A. S. M. MacGregor, R.A.M.C. (T.F.); Capt. (temp. Maj.) P. A. Ople, R.A.M.C.; Lt.-Col. (temp. Col.) B. P. Sewell, O.M.G., D.S.O., R.A.M.C. *Army Medical Service and Royal Army Medical Corps.*—Temp. Capt. R. H. Astbury; Temp. Capt. C. H. Burgess; Lieut. (temp. Capt.) W. M. Cameron; Temp. Maj. J. P. Campbell; Temp. Capt. H. Cardin; Temp. Capt. J. Chabré; Temp. Col. C. C. Choyce, C.B.E.; Temp. Capt. F. H. Diggie, O.B.E.; Maj. (acting Lt.-Col.) W. F. Ellis, O.B.E.; Temp. Capt. W. W. Forbes, O.B.E.; Temp. Capt. N. S. Gilchrist, O.B.E.; Temp. Lieut. E. Giffon; Temp. Capt. E. G. Goldie; Temp. Capt. W. F. Hawkins; Capt. T. F. Kennedy, O.B.E.; Maj. (acting Lt.-Col.) W. E. O. Lunn, M.C.; Capt. (acting Maj.) W. Mathieson; Capt. J. T. Simson; Temp. Capt. O. W. Smith, O.B.E.; Temp. Capt. (acting Maj.) E. B. Smith; Temp. Capt. (acting Maj.) W. H. D. Smith; Capt. B. H. H. Spence; Lt.-Col. G. E. F. Stammers, O.B.E.; Temp. Capt. J. A. H. Telfer.

Royal Army Medical Corps (S.R.).—Capt. H. W. Evans, M.C.; Capt. D. Fraser, M.M.; Capt. (temp. Lt.-Col.) P. S. Vickerman, O.B.E.; Capt. O. Williams.

Royal Army Medical Corps (T.F.).—Maj. L. A. Avery, D.S.O.; Capt. R. Brercliffe, O.B.E.; Capt. C. Douglas; Maj. W. Dyson, O.B.E.; Maj. (acting Lt.-Col.) J. Evans, D.S.O.; Maj. F. Gracie, O.B.M.; Capt. J. Ingalls, O.B.E.; Lt. H. Jessop; Capt. G. J. Linklater; Capt. (temp. Maj.) W. C. Macaulay; Maj. (acting Lt.-Col.) J. W. Mackenzie, O.B.E.; Capt. J. M. Mitchell, M.C.; Capt. (acting Maj.) L. M. V. Mitchell, O.B.E.; Capt. (temp. Maj.) R. Phillips; Capt. (acting Maj.) G. F. Pritchard; Maj. G. C. Taylor, O.B.E.; Maj. A. Thomas; Maj. F. B. Treves, O.B.E.; Capt. (acting Maj.) A. F. Watson, O.B.E.

Indian Medical Service.—Lt.-Col. (temp. Col.) W. H. Ogilvie, C.M.G.; Capt. (temp. Lt.-Col.) A. G. Coulie; Capt. D. L. Graham, O.B.E.; Maj. (temp. Lt.-Col.) E. O. Hodgson, D.S.O.; Lt.-Col. P. S. Lelan, C.B.; temp. Lt. K. R. Ma'an, O.B.M.

Indian Subordinate Medical Department.—Asst. Surg., 4th Class, F. M. Graham; Asst. Surg., 2nd Class, R. H. Hughes; Asst. Surg., 3rd Class, J. A. Pinto.

Australian Army Medical Corps.—Capt. A. M. Aspinall; Lt.-Col., C. B. Blackburn, O.B.E.; Lt.-Col. (temp. Col.) G. P. Dixon, C.B.M.; Col. R. M. Downes, O.M.G.; Maj. N. H. Fairley, O.B.E.; Lt.-Col. (temp. Col.) R. Fowler, O.B.E.; Capt. W. H. Kilner; Lt.-Col. W. L. Kirkwood; Capt. A. T. Robertson; Capt. E. J. Silvertown; Lt.-Col. J. C. Storey, O.B.E.

THE SERVICES.

ROYAL NAVAL MEDICAL SERVICE.

Temp. Surg. Lieuts. J. H. B. Hogg and E. W. Payne, who have been invalided on account of ill-health contracted in the service, to retain their rank.

ARMY MEDICAL SERVICE.

Temp. Major-Gen. Outhbert S. Wallace relinquishes his commission and retains the rank of Major-General.

Temp. Col. H. A. Bruce (Colonel, Canadian Army Medical Corps) relinquishes his temporary commission and retains the rank of Colonel.

ROYAL ARMY MEDICAL CORPS.

Major (temp. Lieut.-Col.) Hewinald V. Cowey relinquishes the temporary rank of Lieutenant-Colonel on re-posting.

Majors to be acting Lieutenant-Colonels: Whilst in command of a Medical Unit: T. S. Blackwell, G. R. Panton, T. H. Gibbon, W. J. Watson. Whilst employed as Assistant Directors of Medical Services of a Division: J. H. Brunskill, W. B. Sparkes.

Captains relinquishing the acting rank of Lieutenant-Colonel and reverting to the acting rank of Major, with pay and allowances of their substantive rank: S. J. Higgins, J. F. Grant.

Temporary Captains relinquishing the acting rank of Major on re-posting: W. G. Waugh, C. F. White, Alan R. Green, J. D. Duncan, C. G. H. Morse, A. H. M. Robertson, J. Lamont.

To be acting Majors: Capt. R. D. Davy, J. P. Little, E. P. A. Smith, F. A. Robinson; Temp. Capt. W. C. Horton, G. L. Keynes, G. D. McLean, J. C. Sale, W. Morris, V. L. Connolly, D. E. Russell, G. H. Davy, W. P. Cooney, C. G. Mackay, J. A. G. Burton, A. R. Elliott, S. S. Dunn (while in command of troops on a Hospital Ship). Whilst specially employed: Temp. Capt. M. McLeod, C. U. Lord; Capt. D. B. McGrigor.

Temp. Major S. H. McCoy, C.A.M.C., to be temporary Lieutenant-Colonel.

Capt. J. J. H. Beckton to be acting Lieutenant-Colonel whilst in command of a Medical Unit.

Temp. Major E. O. Hort relinquishes his temporary commission and is granted the temporary honorary rank of Lieutenant-Colonel whilst specially employed with the Red Cross Society.

Temporary Captains to be acting Majors: G. B. Elliott. Whilst specially employed: A. G. Caldwell, T. E. R. Branch.

Temp. Capt. P. D. Saylor, C.A.M.C., to be acting Major while employed as Director of Sales.

Temp. Capt. H. Gibson to be acting Major while in charge of Glenlondond War Hospital.

Temp. Capt. H. A. Sneltinger, C.A.M.C., to be temporary Major.

Temporary Lieutenants to be temporary Captains: J. H. P. Vivian, J. M. McCormack, E. F. Lawson, J. J. Delaney, O. H. Woodcock, J. Good, H. S. Roberts, A. E. Ede, A. G. Wright.

Temporary Honorary Lieutenants to be temporary Honorary Captains: H. W. Woodward, A. Gregg, D. C. Parmenter (from No. 22 General Hospital, Harvard Unit), W. S. Rutherford.

C. M. Halsall to be temporary Lieutenant.

Officers relinquishing their commissions:—Temp. Majors retaining the rank of Major: R. T. Herron, J. C. MacNeillie, H. Hemsted (Major, S.A. Med. Corps), C. C. Heywood, H. Doddson. Temp. Capt. (acting Majors) C. A. Boyd, J. Lamont, T. I. Bennett, and retain the rank of Major. Temp. Major W. H. Mackenzie. Temp. Capt. R. Briffault, D. P. Williams, H. B. Minshall, W. E. R. Diamond, F. Gravely, J. Boyd. And retain the rank of Captain: A. B. Le Mesurier, A. R. Hall, J. P. O'Connor, G. B. Brown, D. M. Barry, C. H. Brookes, C. A. Moseley, J. Bain, J. C. Macaulay, W. H. Johnston, J. P. O'Flynn, A. Malseed, G. Lawrence, G. Thom, L. H. Bryson, H. W. Windsor-Aubrey, J. P. Fehly, W. Daunt, T. A. Adams, S. J. Simpson, V. B. Kyle, M. Henry, V. B. Ridewood, J. T. O'Boyle, W. Macdonald, D. L. Tate, H. M. Reeve, E. G. Gillies, A. F. Wilson-Gunn, R. C. Cummins, E. C. Abraham, A. S. Dawson, C. F. Knight (acting Major), R. D. Lemon, J. L. Rentoul, J. A. Black, W. Parker, L. S. O'Grady, F. Garrett, R. C. Lowe, J. McA. Hill, S. Rowland, C. S. Vartan, H. T. Lippatt, W. B. Rutherford. Temp. Lieuts. P. N. Twomey, G. E. Oates, N. S. Williams, A. A. Angelis, and retain the rank of Lieutenant. Temp. Capt. (acting Major) Maurice N. Perrin relinquishes his commission on transfer to the R.A.F.

TERRITORIAL FORCE.

Major F. Gracie and Capt. H. F. Humphreys to be acting Lieutenant-Colonels whilst specially employed.

Captains to be acting Majors whilst specially employed: W. H. Milligan, C. M. Gozney, J. M. Pringle, O. M. Nicol, F. Arvor, W. N. P. Williams, J. H. Donnell, L. N. Reece.

Capt. (acting Majors) L. M. V. Mitchell, G. B. J. A. Robinson, W. C. Hodges, H. F. W. Boedicker, F. Wigglesworth, C. M. H. Milner, A. Mowat, and H. W. Wier relinquish their acting rank on ceasing to be specially employed.

Capt. E. W. Richards relinquishes his commission on account of ill-health and retains the rank of Captain.

Capt. H. G. Mallam relinquishes his commission on account of ill-health contracted on active service and retains the rank of Captain.

Major (acting Lieut.-Col.) F. G. Williamson relinquishes his acting rank on ceasing to be specially employed.

Capt. A. W. Nuthall to be Major.

2nd London General Hospital: Capt. (Brevet Major, acting Lieut.-Col.) R. H. Fenwick relinquishes his acting rank on ceasing to be specially employed, and is restored to the establishment.

3rd Northern General Hospital: Capt. (acting Major) J. H. Cobb relinquishes his acting rank on ceasing to be specially employed, and is restored to the establishment.

2nd Northern General Hospital: Capt. A. Richardson is restored to the establishment.

1st Western General Hospital: Capt. R. W. MacKenna is restored to the establishment.

2nd Western General Hospital: Capt. H. Buck and E. Molr are restored to the establishment.

5th Northern General Hospital: Capt. W. I. Cumberlidge is restored to the establishment.

1st London Sanitary Company: Lieut. F. N. McRae to be Captain.

2nd London Sanitary Company: Capt. N. Gebbie to be a Deputy Assistant Director of Medical Services, and to be acting Major whilst so employed. Lieut. H. Jessop to be Captain.

The undermentioned Lieutenants to be Captains and to remain seconded: T. H. Savory, G. N. F. Reddan, J. Dall, A. Sykes, D. Smith.

TERRITORIAL FORCE RESERVE.

Lieut.-Col. E. J. Cross, from Eastern Mounted Brigade Field Ambulance, to be Lieutenant-Colonel.

Lieut.-Col. A. Ogston, from the High Casualty Clearing Station, to be Lieutenant-Colonel.

Major E. B. Waggett, from 3rd London Field Ambulance, to be Major.

Majors P. G. Williamson and R. Stirling, from Attached to Units other than Medical Units, to be Majors.

Major J. McD. Nicoll, from 2nd Northern Field Ambulance, to be Major.

Major J. E. Molson, from Attached to Units other than Medical Units, to be Major.

Capt. J. M. O'Meara, from Eastern Mounted Brigade Field Ambulance, to be Captain.

Capt. H. J. Shanley, from 2nd Northern Field Ambulance, to be Captain.

Capt. C. Corfield, from the 3rd South Midland Field Ambulance, to be Captain.

Capt. (acting Major) D. Lamb, from 4th Scottish General Hospital, to be Captain.

To be Captains: Capt. W. M. Wilson, from 2nd Northern Field Ambulance; T. P. Caverhill (acting Major), D. R. Harris, H. L. Munro, W. J. Lacey-Hickey, J. W. M. Jamieson, from Attached to Units other than Medical Units; W. C. Hodges, from 1st South Western Mounted Bde. Field Ambulance; H. F. W. Boedicker, from 1st South Midland Field Ambulance; A. E. Barnes (acting Major), from 3rd Northern General Hospital; W. D. Carruthers, from 1st London Sanitary Co.; A. Greene from Wessex Casualty Clearing Station; F. Wigglesworth, from 1st West Riding Field Ambulance.

S. Robertson relinquishes his commission on ceasing to be employed, and is granted the rank of Captain.

Lieut. H. B. Pearson relinquishes his commission on ceasing to be employed, and retains the rank of Lieutenant.

ROYAL AIR FORCE.

Medical Branch.—Lieut.-Cols. to be Lieut.-Cols. (Grade A): E. O. B. Carbery, H. Cooper, E. O. Oridland, H. J. Hadden, N. H. Harris, R. H. Mornement, J. St. J. Murphy, T. Philip, W. H. Pope, N. J. Roche, H. B. South, H. V. Wells.

Majors (acting Lieut.-Cols.) retaining the acting rank of Lieut.-Col. whilst employed as Lieut.-Cols. (Grade A): G. N. Biggs, H. C. T. Lungden, T. F. Muecke.

L. B. Stringer (temp. Surg. Lieut., R.N.) is granted a temporary commission as Captain.

VITAL STATISTICS OF ENGLAND AND WALES FOR 1918.

THE following statement shows the birth- and death-rates and the rates of infant mortality in England and Wales, and in certain parts of the country, during the year 1918, the figures being provisional:—

| | Birth-rate per 1000 total popula- tion. | Civilian death-rate per 1000 civilian population (crude rate). | Deaths under 1 year per 1000 births. |
|--|---|---|--|
| England and Wales* | 17.7 | ? | 97 |
| 96 great towns, including London (populations exceeding 50,000 at the Census of 1911) | 17.6 | 18.1 | 106 |
| 148 smaller towns (populations from 20,000 to 50,000 at the Census of 1911) | 18.0 | 16.1 | 94 |
| London | 15.8 | 18.7 | 107 |

* The civilian death-rate for England and Wales cannot be stated at present, the number of non-civilian deaths in the fourth quarter of 1918 not being available.

Major Sir Samuel Scott, Bart., M.P. for St. Marylebone, London, is to introduce the Nurse's Registration Bill drafted by the Central Committee for the State Registration of Nurses.

Correspondence.

"Audi alteram partem."

"TRIVIAL" CASES AT VOLUNTARY HOSPITALS.

To the Editor of THE LANCET.

SIR,—May I traverse one statement that has appeared regarding the future of voluntary hospitals? It is that these hospitals should be relieved from "trivial" cases. I think that there are but few "trivial" cases. Any real departure from health is to be regarded as serious. Early diagnosis and, following that, early treatment are wanted. The beginnings of disease are difficult to diagnose. The recurrent catarrh may be phthisis; the "piles" which the chemist treats, may be rectal cancer; indigestion may be early stomach cancer or what not?; sciatica may mean hip disease. How insidiously many grave nervous diseases begin! Some affections of vision indicating serious disease have slight beginnings; neglected pyorrhoea may lead to many things; either headache or cough may be the beginning of a serious malady; constipation has multitudinous possibilities.

What of the recurrent disabling trivialities with their concomitant periods of economic uselessness, such as nasal catarrh, lumbago, "neuralgia," dysmenorrhoea, "rheumatism," some skin diseases, mal-nutrition? The potentialities of gonorrhoea or of "running ears" are enormous. Then what of the medical student? Is he no longer to see "trivial" cases at his medical school?

I have taken examples of disease just as they occur to me, but they might be multiplied indefinitely. In all of them anyone can recognise the necessity for elaborate and careful diagnosis and treatment. If the voluntary hospital—or whatever the health institution of the future be called—eliminates "trivial" cases from its activities, assuredly there will result grave medical disadvantage to the public.

I am, Sir, yours faithfully,

A. W. SHEEN,

Colonel, A.M.S. (T.F.), Consulting Surgeon,
War Hospitals.
India, Dec. 3rd, 1918.

THE HYPOTHERMIC, OR DEPRESSION, STAGE OF INFLUENZA.

To the Editor of THE LANCET.

SIR,—The depression which follows influenza is so constant that it ought to be regarded as part of the disease. During this period of depression the temperature is subnormal. This stage of subnormal temperature is not generally recognised, but it is of great importance, for it is during this period that the risks of complications are so great, and convalescence is not established until the temperature has reached its normal level again. The condition deserves a name, and I propose to call it hypothermia, and to speak of the stage as the stage of hypothermia, or the hypothermic stage. There is a hypothermic stage after every fever, to which it bears a general relation, being short where the initial fever has been short, and prolonged where, as in typhoid fever, it has been prolonged.

In no fever is the hypothermic stage more pronounced and prolonged than in influenza, and that often in cases where the initial attack has been slight, or where, as in the so-called afebrile cases, the temperature is not known to have been raised at all. During the prevalence of influenza cases are not at all uncommon in which the patients feel cold and miserable and cannot get warm even before a blazing fire or in bed, and the temperature is all the while subnormal. These are, I believe, instances of hypothermia following an unrecognised attack of influenza, for they are not often met with except when influenza is prevalent.

I drew attention to this condition in my account of the epidemic of 1890 and have referred to it frequently since, yet it has not gained general recognition and in the recent clinical descriptions of influenza it is not even referred to. Perhaps if it receives a name it will get the attention it deserves. Anyway, the recognition of this stage is of practical importance, for it is at this period that complications are so likely to occur which might have been avoided. The difficulties often lie with the patients, for as soon as the fever has gone they are so apt to think themselves well and to disregard the doctor's warnings. If they are made to

understand that the hypothermic stage is part of the attack and that they cannot be considered convalescent until the temperature has ceased to be subnormal, and it has risen again to the normal level, the appeal to the thermometer may make them more amenable.

I am, Sir, yours faithfully,
Wimpole-street, W., Jan. 23rd, 1919. SAMUEL WEST.

ACCURATE DIAGNOSIS IN APPENDICITIS.

To the Editor of THE LANCET.

SIR,—I venture to think that in the various papers written upon the subject of appendicitis hardly sufficient attention—in fact no attention—has been given to certain experiments conducted by Dr. Alexander Paine and myself, published in THE LANCET of August 17th, 1912, and elaborated in our volume on "Researches on Rheumatism." These experiments were of some historic interest, for they demonstrated for the first time that it was possible to isolate from human appendicitis a micro-organism which on intravenous inoculation reproduced the disease in rabbits. The specimens were presented to the Museum of the Royal College of Surgeons of England.

Their importance lies in the demonstration that the infection is a blood infection *not* attacking from the lumen of the appendix, but from the *peritoneal surface* by the blood stream. Every step in the process was demonstrated and the pathology is fully illustrated in our book. As a result of the infection "ballooning" of the appendix may occur without any concretion, and whether or not the "balloon" bursts clearly depends on the extent of necrosis of the wall infected. The result of the inflammation is catarrh in the tube, which, when the process is chronic, causes the formation of a faecal stone, and this in turn adds the factor of traumatism. The strictures are the result of local chronic inflammation from the blood infection and a "mitral stenosis" of the lumen of the duct, if I may coin a term to save space. The stricture complicates the history of appendicular disease, as all are aware. The technical difficulties of the bacteriological investigations are described, and a method for overcoming them detailed, in our book.

I believe it to be of importance that it should be realised that appendicitis is in origin a blood infection and not a local infection, for the difficulties of early detection and obscurities in the history are made much more obvious when the pathology is turned outside-in and not inside-out, as is so often the case.

I am, Sir, yours faithfully,
Devonshire-place, W., Jan. 26th, 1919. F. JOHN POYNTON.

ACUTE APPENDICITIS AND ACUTE APPENDICULAR OBSTRUCTION.

To the Editor of THE LANCET.

SIR,—The paper on this subject by Mr. S. T. Irwin in your issue of Jan. 18th is of great interest to me, bringing forward as it does the most valuable corroborative evidence of the thesis which I put forward at the meeting of the British Medical Association in July, 1914—namely, that there are two acute diseases of the appendix—acute inflammation and acute obstruction. I maintained that the one disease differed from the other not only in its symptoms and pathology, but also in its danger to life and in the urgency of the treatment required.

In my original paper¹ I brought forward clinical and experimental evidence which appeared to me to be conclusive in this connection. Later experience has confirmed me in my views, and I have now no hesitation in saying that our teaching of the symptomatology and pathology of acute appendicular disease should be based on those clear and distinctive lines. Unless this is done the description of the symptoms of so-called appendicitis must be qualified in so many points that it ceases to be distinctive. With two well-defined clinical pictures based on sound pathology the student and practitioner are in a position to detect the different forms of acute appendicular disease in their early stages, and by recognising the great urgency for immediate operation in the cases of obstruction to reduce to a minimum the needless loss of life which still obtains in this disease.

I am, Sir, yours faithfully,
Edinburgh, Jan. 20th, 1919. D. P. D. WILKIE.

A PERSONAL RETROSPECT OF GENERAL PRACTICE.

To the Editor of THE LANCET.

SIR,—I have read with interest, sympathy, and the appreciation of experience, the thoughtful paper by Dr. James Pearse, which appears under the above title in THE LANCET of Jan. 25th. Its excellence justifies the prominence you have given it. The advocacy of the interests of the general practitioner by THE LANCET, from its inception under its Founder—Thomas Wakley the first—until the present day, gives you an authoritative position in discussing his status and prospects.

Times change and we with them are altered, and one would like to think that the position of the general practitioner in the present day and his prospects had altered for the better. He would, however, be a bold man who would maintain this thesis. My own retrospect of practice, first as a general practitioner and later as a consultant, now reaches rather more than 40 years, a period nearly equally distributed in the two spheres of work. I may therefore claim to be in a position to appreciate Dr. Pearse's account of the difficulties and the advantages and disadvantages of the environment of the general practitioner and his relation to other branches of the profession. Time was when, in England especially, a considerable gulf yawned between the practitioner and the consultant, and the infringement of the commercial interests of either was resented by both. Even now there is an echo of this in the occasionally insistent angry query, "What is a consultant?" In the humblest days of the visiting apothecary the action of the College of Physicians of London in supplying good drugs to the poor was resented by the former, aided by interested friends among the physicians, as related in Garth's Dispensary, at a time when medicine languished and men "studied lucre more and science less."

It was the calculated design, on the other hand, of the consultant to keep the chasm wide between the two classes, when THE LANCET was founded, which brought its doughty first editor and proprietor into the field as a medical informer and reformer, and Thomas Wakley's work should never be forgotten by that section of the body which he left with at least some title to be considered a liberal profession rather than a debased trade. Whether the action of more recent medical politicians is likely to have an equally beneficial effect may be gravely doubted. Wakley's efforts were towards a unification of the profession. Present-day tendencies appear to be towards its undue division. He, by his educative work, promoted evolution from the general to the particular; now, by a hopeless gaze upon the increase of knowledge and an unwise specialism, we are in danger of fatally dissolving an organic whole into its component parts. As Dr. Pearse points out, this danger is less in country districts than in larger centres of population, where the general practitioner, robbed of responsibility, has too easy opportunity of delegating work, and tends to become a mere "sifter" of cases, to use Dr. Pearse's term.

Research and practice cannot be divorced in any sphere of cultivated medicine without detriment to the quality and utility of both. Research cannot be fruitfully pursued without touch with practice. Positions of more particular research may arise in general investigation, but there is a danger in the creation of special research posts to be filled by men without active touch with general experience. Even the shortness of life and the length of art do not justify the creation of such.

With all that Dr. Pearse says of the influence of individual temperament and the education of the man preparing for practice one must be in full agreement. The value of the inspiring teacher cannot be overestimated. It needs, however, an inspired teacher to inspire others, and, unfortunately, he cannot be produced even under the fostering influence of that twentieth-century recipe for genius, a large salary! The student, once inspired, remains a student all his life, and the uninspired student had very much better adopt some other calling than medicine, which is a rough road not often leading to a gold mine. Duly educated, however, and once in the profession, the secret of progress for the general practitioner, promotive alike of his own growth and benefit and of the public good, is contained in a single word—*collaboration*.

¹ Brit. Med. Journ., Dec. 5th, 1914.

The writer can recall a group of men who, in a then comparatively detached part of this metropolis, by collaboration in research in general practice (they were also the first so-called "team workers" among practitioners) produced, in its own degree, work comparable with any other work in interest and utility, and begot a camaraderie and punctilio in ethics which rendered it a joy to be a general practitioner, notwithstanding days and nights laborious in more senses than one. Many of those collaborators have passed away, including one—the Atlas who bore that little world—and all largely unsung, some poor, but none, as Dr. Pearse says, unhonoured or unwept. That under any State system, in being or contemplated, the same spirit will be evoked to the benefit of the individual, the profession, and the community is more than doubtful. The intrusion of the State into medicine tends, and in the opinion of many will ever tend, to destroy the individuality and independence of the practitioner, and, what may appeal to the State more, to impair also regard for the patient as an individual and his freedom as a citizen, and, with this, sufficient medical interest in him.

Jan. 27th, 1919.

I am, Sir, yours faithfully,
F.R.C.P.

VENEREAL DISEASES IN EGYPT.

To the Editor of THE LANCET.

SIR,—In the report of my lecture on the above subject which you were good enough to print in your issue of Jan. 25th, it is implied that during the first five months of 1916 10,000 Australian troops were infected.

Will you permit me to correct the statement? The total known infections of all troops in Egypt were 10,000. I did not attempt to discriminate between the various subdivisions of the army.—I am, Sir, yours faithfully,

Jan. 27th, 1919.

JAMES W. BARRETT.

WAR DEAFNESS.

To the Editor of THE LANCET.

SIR,—Dr. P. McBride, commenting in your issue of Jan. 25th on the contribution of Dr. C. S. Myers to the study of shell shock (THE LANCET, Jan. 11th), gives it as his opinion that functional deafness is extremely rare and that the statement—

"Every physician of experience must have met with patients suffering from functional deafness whose sleep has not been in the least disturbed by the loudest noises"—

would have to be answered by him with a decided negative.

I have had two cases of absolute functional deafness as the only symptom following shell explosion, and in both sleep was not in the least disturbed by noise.

One case is of special interest in that the patient was tested from this point of view by Mr. Arthur Cheate, who failed to wake the sleeper with the loudest noises right over his ear. The duration of the symptom in this case was three months and I could not satisfy myself that he even gave a flicker with the dropped-bucket test. Mr. Cheate gave it as his opinion that the case was functional, and normal hearing was restored after five days' treatment by suggestion.

An additional interest is attached to this case in that though at first he showed genuine delight at the recovery of his hearing he later developed anxiety neurosis. It shows the disposition to equivalent symptoms in hysteria and also that suggestion, though a valuable therapeutic agent for the removal of symptoms, is insufficient as a method of cure.

I am, Sir, yours faithfully,

E. PRIDEAUX,

Temporary Captain, R.A.M.C.

Ewell War Hospital, Jan. 26th, 1919.

CAUSES AND INCIDENCE OF DENTAL CARIES.

To the Editor of THE LANCET.

SIR,—I regret that Mr. Denison Pedley should have found my letter confusing. How far the fault here rests with him or with me I leave others to decide. Mr. Pedley seems much concerned to prove that I have exaggerated the amount of dental disease in this country. I am content to know that so high an authority as Dr. Sim Wallace does not share his opinion. Mr. Pedley's outlook and my own regarding the practical handling of the dental question are entirely

different. He pins his faith largely on the establishment of "school dental treatment centres for the children of the elementary schools." This is mere patchwork. Our primary aim should be prevention. It has been shown conclusively that dental disease in children can be reduced almost to the vanishing point by the adoption of quite simple precautions, and it is the plain duty of our profession to bring this pregnant truth home to the people of this country and to do its best to remove a national disgrace.

I understand from a highly educated native doctor that it is a general custom with the Hindus to rinse the mouth out after every meal from the time of weaning onwards. Even a beggar will ask for water for this purpose. The care of the teeth is with them almost a religion, and not to have good teeth a disgrace which is felt keenly.

I am, Sir, yours faithfully,

Cavendish-square, W., Jan. 28th, 1919. HARRY CAMPBELL.

MEDICAL PRACTITIONERS AND THE DETECTION OF CRIME.

To the Editor of THE LANCET.

SIR,—The National Council for Combating Venereal Diseases are anxious in the public interest to secure the enforcement of the Venereal Diseases Act, 1917.

With reference to the note under this title in your issue of Jan. 18th we wish to draw your attention to the fact that Dr. Otto May undertook, on behalf of the Council, to assist in obtaining the conviction of a quack in active practice.

Though in many ways repugnant to him, he considered the interest of the community and of the individual sufferers as paramount, and therefore sacrificed his personal feelings and undertook this disagreeable duty.

Dr. May was acting throughout as a representative member of the public and not in his capacity as a medical man. Therefore the analogy drawn in the article between his action and that of a medical man dealing with a case of abortion is not a true parallel.

I am, Sir, yours faithfully,

S. GOTTO,

General Secretary, National Council for Combating Venereal Diseases.

Jan. 28th, 1919.

* * We are certain that Dr. May sacrificed his personal feelings to undertake a disagreeable public duty, and we respect him for it. We said expressly that we did not question that he was actuated by a sense of public duty. But a medical man could obviously be actuated by the same sense in dealing similarly with a case of abortion. The analogy which we drew was a true one.—ED. L.

PLACE AUX EMBUSQUÉS?

To the Editor of THE LANCET.

SIR,—In your issue of Jan. 25th Mr. A. W. Comber does well to draw, under this title, the attention of the medical world in general to the action of the Birmingham Health Committee with regard to the Birmingham Pensioners' Hospital. This and other happenings—for example, the scheme for priority of demobilisation, which gives the same number of points to the man who has never been out of his own home and to the man who has been on active service all the time—are serious portents of what is going to occur in the near future.

It was surely too obvious that an R.A.M.C. officer who had been on active service, and who accordingly must know our soldier and his ailments at first hand, would be better qualified to look after him than a doctor who has not had active service experience. That, quite apart from the invitation of the advertisement—"senior officer preferred." Presumably the gentleman who has been appointed will (under the Central Medical War Committee's scheme) shortly be called up to replace in the Army one of the unsuccessful applicants for the post. May I bring this point of view to the notice of the Central Medical War Committee?

I am, Sir, yours faithfully,

Jan. 28th, 1919.

"RESERVE."

CENTENARIANS.—Mr. Edward P. Smart, of Sparkford, Somerset, celebrated the 100th anniversary of his birthday on Dec. 23rd, 1918.—Mrs. Arthur Mozley, of Malvern View, Cheltenham, celebrated the 104th anniversary of her birthday on Jan. 22nd.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following are the results of the Triple Qualification Examinations:—

THIRD EXAMINATION.

Douglas Chiene Scotland, James Foster Cook, Lachman Singh Ahluwalia, Arthur Henry Jacobs, Ronald MacKinnon, and Bernard McLaughlin.

Pathology.—Sayed Chaleb and Stanley Sewell Nicholson.

Materia Medica.—Perceval Charles Holden Homer.

FINAL EXAMINATION.

Lazarus Samuels, William Francis Gawne, Lachman Singh Ahluwalia, Arthur Kinsey Towers, Victor Albert Rankin, John Vaughan Griffith, George Alexander Grandsault, Quintin Stewart, William Brownlee Watson, Ben Cheifitz, and Richard Irving Fuggle.

Medicine.—Daniel Adrian Stegman, Thomas Ferguson Minford, James Miller Speirs, Reginald Leslie Wright, and John Archibald Steel Campbell.

Surgery.—William Gibb, and John Archibald Steel Campbell.

Midwifery.—Hassan Amin Madiwar, Thomas Ferguson Minford, Gilbert Llewellyn Stanley, James Miller Speirs, Reginald Leslie Wright, and Sidney Hill Waddy.

Medical Jurisprudence.—Daniel Adrian Stegman, Walter Carew, Veeravagu Katheravel Paramanayagam, Donald Mackay, Gordon Beveridge, and Leo Hugo Peries.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held at Queen Anne's Gate Buildings, Westminster, on Jan. 23rd, with Sir Francis H. Champneys in the chair. Two midwives were struck off the Roll, the following charges, amongst others, having been brought forward:—

Neglecting to wash the patient's external parts with soap and water and to swab them with an efficient antiseptic solution after the termination of the labour and during the lying-in period, as required by Rule E. 8; neglecting to remove the soiled and stained linen from the neighbourhood of the patient as soon as possible after the labour and before leaving the house, as required by Rule E. 11; neglecting to give all necessary directions for securing the comfort and proper dieting of the mother and child during the lying-in period, as required by Rule E. 12; not being scrupulously clean in every way, as required by Rule E. 2; not taking and recording the pulse and temperature of patients at each visit, as required by Rule E. 14; not entering records of pulse and temperature in a notebook or on a chart carefully preserved, as required by Rule E. 14, and not keeping a register of cases as required by Rule E. 24. A child suffering from inflammation of or discharge from the eyes, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E. 21 (5), and when called to a confinement she did not take with her the appliances and antiseptics required by Rule E. 3.

A meeting was held on Jan. 23rd, when a letter was considered from the Local Government Board asking the Central Midwives Board to reconsider the form of the draft rules approved at the Board meeting of Dec. 19th, 1918, requiring a midwife to notify the Local Supervising Authority when she has advised artificial feeding. The Board decided that Draft Rule E. 12A be amended to read as follows:—

"A midwife must forthwith notify the Local Supervising Authority of each case in which it is proposed to substitute artificial feeding for breast feeding."

—The Board, having considered the appointment, for a limited period, of an assistant secretary to the Board, decided (a) that it is desirable to appoint an assistant secretary with a view to his appointment as secretary, should the Board so determine, on the retirement of the present secretary on Sept. 6th next; and (b) that the chairman, Miss Paget, and Dr. West be appointed a sub-committee to consider applications and to bring before the Board the names of three candidates for appointment of one of them by the Board.—The secretary reported that copies of the draft rules regulating the payment of expenses incurred by members in respect of their attendance at meetings of the Board had, on Dec. 20th, 1918, been forwarded to the Scottish and Irish Midwives Boards for their information, and that no comment thereon had been received from either Board. The Board decided that the secretary be directed to forward to the Privy Council copies of the draft rules framed by the Board under Section 4 of the Midwives Act, 1918, and to request the Privy Council to approve them.—The secretary reported that copies of the draft rules deciding the conditions under which midwives may be suspended from practice in penal cases had on Dec. 20th, 1918, been forwarded to the Scottish and Irish Boards for their information and that no comment thereon had been received from either Board. The Board decided that the secretary be directed to forward to the Privy Council copies of the draft rules framed by the Board under Section 6 of the Midwives Act, 1918, and to request the Privy Council to approve them.—The Board having considered the form of certificate to be granted to women certified by the Board by reason of holding an equivalent certificate obtained in any other part of His Majesty's Dominions directed that the draft forms of certificates as submitted by the secretary be adopted and that they be forwarded to the Privy Council for approval.

IMPERIAL STUDIES LECTURES.—A course of six public lectures, arranged in connexion with the Imperial Studies Committee of London University, will be given at King's College, Strand, W.C., on Wednesdays at 5.30 P.M. The first lecture is by Professor W. D. Halliburton on Physiology and the Food Problem, with Sir Alfred Keogh in the chair. The other lectures will be announced from week to week in the Medical Diary. Cards of admission (free) on application to the lecture secretary.

MEDICAL INSPECTION OF SCHOOL CHILDREN.—At Exeter last week a parent summoned a school medical officer and the school nurse for assaulting his daughter, aged 11 years, by conducting a medical inspection of the child's eyes without his consent. The summons was dismissed. Another summons was then proceeded with, when the parent was charged with neglecting to have the child's eyes attended to. The defendant suggested that he should be allowed to take the girl to an ophthalmic surgeon and to provide spectacles if necessary. The bench of magistrates agreed to this proposal and adjourned the case for a week.

ROYAL INSTITUTION.—On Tuesday next, Feb. 4th, at 3 o'clock, Professor J. T. Macgregor-Morris will deliver the first of a course of two lectures at the Royal Institution on the Study of Electric Arcs and their Applications. On Thursday, Feb. 6th, Dr. W. Wilson will give the first of two lectures on the Movements of the Sun, Earth, and Moon, illustrated by a new astronomical model. The Friday evening discourse on Feb. 7th, at 5.30, will be delivered by Professor J. G. Adami on Medical Research in its Relationship to the War; on Feb. 14th by Professor Cargill G. Knott on Earthquake Waves and the Interior of the Earth.

THE LATE MR. W. A. E. HAY, M.R.C.S., L.S.A., J.P.—William Alfred Edward Hay died at his residence, West Allington, Bridport, on Jan. 18th, in his 66th year. The deceased, who belonged to an old Dorsetshire family, had been in practice for many years in Bridport. He held several appointments and was medical officer of health for the Bridport rural district. He was formerly surgeon-major in the 1st V. B. Dorset Regiment and was a justice of the peace for the borough of Bridport.

ROYAL MEDICAL BENEVOLENT FUND.—At a meeting of the committee, held on Jan. 14th, 17 cases were considered and £175 voted to 14 of the applicants. The following is a summary of some of the cases relieved:—

Daughter, aged 50, of M. B. Lond. who practised in Staffordshire and died in 1885. Loss of income through bad investments. Bad health will not allow applicant to work. Only income 10s. a week from a nephew and help from the Guild. Relieved four times, £40. Voted £12 in 12 instalments.—Widow, aged 70, of L.R.C.P. & S. Irel. who practised in Essex and died in 1886. Applicant left without means and lives with a married son who has a large family and is unable to help his mother. Pays 3s. per week rent. Only income an Epsom Pension of £30. Relieved seven times, £34. Elected to an annuity of £20.—L.R.C.P. & S. Edin., widower, aged 61, who practised at Old Kirkpatrick. Applicant suffers from spastic paralysis. Has one son who allows £50 a year; other income £20 from another charity. Rent £26 10s. Relieved 14 times, £168. Voted £12 in 12 instalments.—Daughter, aged 65, of M. D. Edin. who practised at Baling and died in 1873. Applicant, along with two sisters, endeavours to make a living by taking in paying guests, but finds it difficult to meet expenses. Other income: dividends, £46; from relatives, £30; rent £40. Wants help to provide coal. Relieved three times, £35. Voted £10.—Widow, aged 50, of L.S.A. Lond. who practised in London and died in 1911. Was left with two young boys, now aged 14 and 16 years. Precarious health prevents applicant from doing any permanent work. Sister-in-law allows 30s. per week. Rent £18 a year, and £18 paid for insurance for children. High cost of living makes it impossible for applicant to manage. Relieved three times, £25. Voted £10.—Wife, aged 52, of L.R.C.P. Irel., separated from her husband since 1905. Had to bring up three children, now aged 18 to 23, the youngest, a son, in the Army. Other children help when possible. Has a pension of £21 from the R.U.K.B.A. Has done some work at a V.A.D. hospital, but this has now finished. Is suffering from an eye trouble. Relieved five times, £50. Voted £12 in 12 instalments.—Widow, aged 53, of M.R.C.S. Eng. who practised at Bexhill and died in 1912. Has two children, the eldest 24, who is a clerk, not living at home, and the youngest daughter, aged 14 years, at St. Anne's School, and has to be kept during the holidays and provided with clothes. Applicant has post as companion, at £20 per annum. Relieved four times, £40. Voted £10 in two instalments.—Widow, aged 33, of M.R.C.S. Eng. who practised at Swansea and died in 1914. Applicant lives with her mother, who is unable to keep her. Only child, aged 10, at St. Anne's School, but has to be kept during the holidays and clothed. Applicant's health is bad, and she is unable to work. Helped by the Guild. Relieved four times, £48. Voted £12 in 12 instalments.—Daughter, aged 66, of M.R.C.S. Eng. who practised at Watford and died in 1879. Owing to ill-health unable to work. Income from property £26; R.U.K.B.A., £26; and occasional help from friends. Rent 3s. per week. Relieved 12 times, £135. Elected to an annuity of £10.—Daughter, aged 68, of L.R.C.S. Edin. who practised at Liverpool and died in 1893. Applicant endeavours to earn a living by letting rooms, but owing to the high cost of living finds it impossible to meet expenses. Health has been bad recently. Rent £25 per annum. Has received about 16s. per week by letting rooms. Relieved twice, £17. Voted £12 in 12 instalments.

Subscriptions may be sent to the acting honorary treasurer, Dr. Samuel West, at 11, Chandos-street, Cavendish-square, London, W. 1.

JAN. 26TH was observed in Bristol as Hospital Sunday.

In the Governors' Hall at St. Thomas's Hospital, to-day (Friday, Jan. 31st), at 4.30 P.M., Major-General Cuthbert Wallace, C.B., C.M.G., will deliver a lecture on the Surgical Work of a Casualty Clearing Station.

THE King of the Belgians has conferred the Chevalier de l'Ordre de Léopold upon Dr. A. George Bateman, of London, for services rendered to Belgium during the war.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.—As a result of the Hospital Sunday collections on Oct. 27th, 1918, the sum of £623 was raised for the funds of this hospital.

ADVISORY COMMITTEE ON ANTHRAX.—The Home Secretary has appointed an advisory committee to deal with the establishment of a trial disinfecting station as recommended by the Departmental Committee on Anthrax, and with other measures of protection against accidental infection. The secretary of this as of the previous committee is Mr. G. E. Duckering, one of H.M. Inspectors of Factories. Address: 72, Bridge-street, Manchester.

THE LATE DR. B. W. CHERRETT, OF NAIROBI.—Mr. Bertram Walter Cherrett, M.B., B.S. Lond., died at Nairobi, British East Africa, of influenza, on Nov. 4th. Trained at St. Bartholomew's Hospital, London, he qualified in 1906, and for eight years past had been medical officer of health to the Protectorate. Known all his life as a cheery worker, the Nairobi *Leader* speaks of him as the type of British official imbued with the "true spirit of public service."

THE Swiney prize of the Royal Society of Arts for 1919 has been awarded, as was announced in THE LANCET last week, to Dr. C. A. Mercier for his book, "Crime and Criminals," published in December, 1918. The prize is a silver-gilt cup designed by MacIise, and of the value of £100, and money to the same amount. It is awarded every fifth year to the writer of the best work on jurisprudence published since the last award, being given alternately for general jurisprudence and for medical jurisprudence. The prize was founded in 1844, and in the 75 years of its existence has been awarded sometimes to very distinguished men. Dr. Mercier won the Swiney prize in 1909, and this is the first occasion on which it has been awarded to the same candidate for the second time.

DEATH OF MR. G. V. LANGWORTHY, M.R.C.S., L.M. Eng., L.S.A.—George Vincent Langworthy died recently at his residence, Modbury, Devon, in his 83rd year. He was the third son of the late Mr. W. F. Langworthy, surgeon, of Modbury. Mr. Langworthy, who qualified in 1864, practised for many years in Modbury with his brother, Mr. W. F. Langworthy, but had retired from active work for more than 20 years. He had an extensive practice, and was highly esteemed in the district.

SCOTTISH POOR-LAW MEDICAL OFFICERS' ASSOCIATION.—In their report for the year 1918 the committee state that practically no correspondence had taken place with regard to the grievances noted in their annual report for 1917, and that up to the present time the offer of the secretary of the Association to accompany a deputation of the Highland members to bring their grievances before the Highlands and Islands Service Board had not been accepted. The grievances referred to were the unsatisfactory conditions as regards income, area, and facilities attaching to the work of the medical officers in the crofting counties. During the year a circular had been sent to parish councils asking for an increase in salaries, and although the total number of increases granted was not known, the secretary reports that he has knowledge of increases of a rise of 25 to 50 per cent. reported in more than 50 cases.

SPECIAL EXAMINATIONS FOR THE PRIMARY F.R.C.S. ENG.—The Council of the Royal College of Surgeons of England has decided to hold a special primary examination in anatomy and physiology for the Fellowship for surgeons who hold or have held commissions during the war and have done commendable surgical work during their service. The examination will be partly written and partly viva voce; the questions asked will have a direct bearing on practical surgery and will not include morphology, embryology, histological or chemical methods, or practical examination in the use of the apparatus of the physiological laboratory. The first of these special examinations is to be held early in May and the second in November of the current year. A third examination is planned for some time in 1920. Entrance will be permitted only to one such examination. Candidates must be Members of the College or graduates in medicine of a university recognised by the College. Further particulars may be obtained from Mr. F. G. Hallett, at the Examination Hall, Queen-square, London, W.C. 1.

Appointments.

BRASH, EDWARD JOHN YELVERTON, B.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., has been appointed Public Vaccinator for Exeter, and Medical Officer for the No. 1 District.
COATES, VINCENT MIDDLETON, L.R.C.P., M.R.C.S., Pathologist at the Salonica Military Hospital.
HODDER, A. E., M.B., B.C., Certifying Surgeon under the Factory and Workshop Acts for the Stafford No. 2 District of the County of Stafford.
McMURRAY, A., F.R.C.S., acting Assistant Medical Officer of Health, Johannesburg.
REYNOLDS, FRANCIS MORTIMER, M.B., C.M. Edin., Medical Officer of Health for Seaton (Devon).
RIGGALL, ROBERT M., M.R.C.S. Eng., L.R.C.P. Lond. & Edin., Surgeon Lieut.-Commander R.N., Medical Officer to the Clinic of Functional Nerve Disorders under the Ministry of Pensions.

Vacancies.

For further information refer to the advertisement columns.

Alnwick Infirmary.—H.S. £150.
Bedford County Hospital.—Res. M.O. £150.
Birkenhead Borough Hospital.—Jun. H.S. £170.
Birmingham Corporation Pre-Maternity and Infant Welfare Work.—Female Doctor. £350.
Birmingham General Hospital.—Vacancies on Res. Staff.
Birmingham, Queen's Hospital.—Hon. S.
Buenos Aires, British Hospital.—Senior R.M.O. and Asst. R.M.O. £500 and £450.
Cardiff City.—Female Asst. M.O. £350.
Chester Royal Infirmary.—H.S. £200.
Devonport Royal Albert Hospital.—Res. H.S. £200.
Edmonton Infirmary.—Asst. M.O. £1 per day.
Folkestone, Royal Victoria Hospital.—H.S. £150.
Glamorgan County Council.—Inspection of Children in Public Elementary Schools.—Three M.O.'s. £400.
Govan District Asylum, Cardonald, Glasgow.—Sen. Asst. M.O. Also Jun. Asst.
Harrogate Infirmary.—H.S.
Isleworth Infirmary.—Asst. M.O.'s. £300 and £250.
Italian Hospital.—H.S. £150.
Johannesburg, South African School of Mines and Technology.—Professors of Anat. and Physio. £1000 in each case.
Kingston-upon-Thames Borough Education Authority.—School M.O. £300.
Leeds General Infirmary.—Res. S.O. £150. Res. Aural O. £100. Oph. H.S. £50. Res. M.O. £60. Also Two H.S. and Two H.P.
London Homoeopathic Hospital, Great Ormond-street and Queen-square, Bloomsbury, W.C.—Clin. Path. and Bact. £200.
Norwich, Norfolk and Norwich Hospital.—Fourth Res. Surg. O. £200.
Portsmouth Corporation Mental Hospital.—Jun. Asst. M.O. £250.
Portsmouth Workhouse Infirmary, Workhouse, and Children's Home.—First Asst. M.O. £500.
Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Asst. P.
Royal National Orthopaedic Hospital.—Res. H.S. £100.
St. Bartholomew's Hospital.—Refraction Assts. One guinea per session.
St. Mark's Hospital for Cancer, Fistula, and Other Diseases of the Rectum, City-road, London, E.C.—H.S. £250.
Smethwick County Borough.—M.O.H. £300.
South London Hospital for Women.—Female Asst. Path. £150.
Southport General Infirmary.—Jun. H.S. £5 5s. per week.
Teakbury Union.—M.O. £55.
University of London.—Examiners.
Warwickshire County Council.—Asst. M.O.H. £400.
Western Ophthalmic Hospital, Marylebone-road, N.W.—Vacancies on Medical Staff.
West Ham Union Sick Home, Forest-lane, Stratford, E.—Temp. Res. Asst. M.O. £6 6s. per week.
Westmorland County Council.—Female Asst. M.O. £400.
Windsor, King Edward VII. Hospital.—Asst. Hon. S.
THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Hitchin.

Births, Marriages, and Deaths.

BIRTHS.

BATE.—On Jan. 28th, at Hove, the wife of Captain A. G. Bate, R.A.M.C. (T.F.), of a daughter.
COLLYNS.—On Jan. 10th, at Kampala, Uganda, the wife of John Moore Collyns, M.B., Colonial Service, of a son.
McMILLAN.—On Jan. 19th, 1919, at Dublin, Patricia (née Smyth), the wife of Temporary Surgeon Kenneth H. McMillan, R.N., of a son.

MARRIAGES.

BUTCHER-SINCLAIR.—On Jan. 18th, at the Church of St. Oswin, South Shields, Walter Herbert Butcher, Temporary Surgeon-Lieutenant, R.N., to Cecilia St. John, youngest daughter of D. Sinclair, Brinkburn-terrace, South Shields.

DEATHS.

COGHILL.—On Jan. 24th, at Guildford, Harold Sinclair Coghill, M.B., Ch.B. Edin., D.T.M. Lond. (W.A.M.S.), aged 38.
LE QUESNE.—On Jan. 24th, at "Melbury, Havre des Pae, Jersey, Edwin Joseph Le Quesne, M.R.C.S., L.R.C.P., in his 68th year.
SAWYER.—On Jan. 27th, at his residence, Haseley Hall, Hatton, Warwick, Sir James Sawyer, M.D. Lond., F.R.C.P. Lond., in his 75th year.
N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY, Feb. 6th.—Papers:—Mr. A. Mallock: Note on the Elasticity of Metals as affected by Temperature.—Mr. W. L. Cowley and Mr. H. Levy: Vibration and Strength of Struts and Continuous Beams under End Thrusts (communicated by Sir Richard Glazebrook).—Mr. A. Dey: A New Method for the Absolute Determination of Frequency (with a prefatory note by Mr. C. V. Haman) (communicated by Dr. G. T. Walker).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W. 1.

Wednesday, Feb. 5th.

SOCIAL EVENING: at 8.30 p.m.

Sir John Blain-Sutton will discourse on "Gizzards and Counterfeit Gizzards," illustrated by Specimens. The Library will be open and visitors are invited to raise and discuss any question in which they are interested. (Tea, coffee, and smoking.)

Medical Officers of the Navy, R.A.M.C., the Dominions, United States, and the Allies are cordially invited.

MEETINGS OF SECTIONS.

Tuesday, Feb. 4th.

PATHOLOGY (Hon. Secretaries—Gordon W. Goodhart, J. A. Murray): at 8.30 p.m.

Papers:

Dr. J. A. Murray: A Staining Method for Bacteria in Tissues.

Dr. Murray will also give a Demonstration of Acariasis of the Lungs in the Macacus Rhesus.

Mr. C. A. R. Nitch and Professor S. G. Shattock: Diffuse Emphysema of the Intestine.

Wednesday, Feb. 5th.

OPHTHALMOLOGY (Hon. Secretaries—Leslie Paton, Malcolm Hepburn): at 8.30 p.m.

Papers:

Dr. James Taylor: Changes in the Sella Turcica in Association with Leber's Atrophy.

Dr. W. Wallace: Fundus Changes resulting from War Injuries.

Mr. R. Foster Moore: A Case of Sympathetic Ophthalmitis with Fundus Changes.

Cases:

Mr. A. C. Hudson: Retinal Degeneration following Intraocular Foreign Body.

Thursday, Feb. 6th.

OBSTETRICS AND GYNÆCOLOGY (Hon. Secretaries—Comyns Berkeley, J. S. Fairbairn): at 8 p.m.

Discussion:

On Reconstruction in the Teaching of Obstetrics and Gynecology to Medical Students. Speakers:—

Dr. Walter Griffith: A General Survey of the Subjects to be Taught and of the Methods of Teaching them.

Dr. J. S. Fairbairn: The Training of the Student from the Standpoint of Preventive Medicine.

Dr. Lovell Drage: The Teaching of the Student from the Point of View of a General Practitioner.

Dr. Russell Andrews, Dr. Blacker, and Dr. Amand Routh will also speak.

Dr. Lapborne Smith will show "The Obstetric Helper."

Those wishing to take part in the Discussion are requested to send in their names to the Senior Hon. Secretary of the Section (Mr. Comyns Berkeley, 53, Wimpole-street, W. 1).

Copies of the Opening Papers will be available for distribution to intending speakers a week before the meeting on application to the Secretary of the Society.

Friday, Feb. 7th.

LARYNGOLOGY (Hon. Secretaries—Frank A. Rose, Irwin Moore): at 4.30 p.m.

Cases will be shown at 3.45 p.m. by:—

Dr. Andrew Wylie, Mr. Stuart-Low, Mr. G. Seccombe Hett, Dr. Irwin Moore, Dr. W. S. Syme, and Dr. Macleod.

RÜNTGEN SOCIETY, at the Royal Society of Arts, 18, John-street, Strand, W.C.

TUESDAY, Feb. 4th.—8.15 p.m., General Meeting. Paper: Dr. F. Herniman-Johnson, Hon. Capt., R.A.M.C.: Protection in Diagnostic Work: A Consideration of the Effects of Scattered Rays and Secondary Rays.—Lieut. W. Makower will describe and exhibit a Langmuir Exhaust Pump.

HUNTERIAN SOCIETY.

WEDNESDAY, Feb. 5th.—7 p.m., Annual Dinner at Cannon Street Hotel, the President, Dr. Langton Brown, in the chair.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, in the Theatre of the College, Lincoln's Inn Fields, W.C.

MONDAY, Feb. 3rd.—5 p.m., Hunterian Lecture.—Prof. A. J. Walton: The Surgery of the Spinal Cord in Peace and War.

WEDNESDAY—5 p.m., Hunterian Lecture.—Prof. D. Ligat: The Significance and Surgical Value of Certain Abdominal Reflexes.

FRIDAY—5 p.m., Hunterian Lecture.—Prof. G. Taylor: Abdominal Injuries of Warfare.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY, Feb. 3rd.—2 p.m., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simon: Diseases of Women.

TUESDAY—2 p.m., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY—10 a.m., Dr. Arthur Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. 2 p.m., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THURSDAY—2 p.m., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye. **FRIDAY**—10 a.m., Dr. Simon: Gynaecological Operations. 2 p.m., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Banks Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. **SATURDAY**—10 a.m., Dr. Arthur Saunders: Diseases of Children. Dr. Banks Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 p.m., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

UNIVERSITY OF LONDON, KING'S COLLEGE, AND KING'S COLLEGE FOR WOMEN.

Course of Six Public Lectures arranged in conjunction with the Imperial Studies Committee of the University on Physiology and National Needs:—

WEDNESDAY, Feb. 5th.—5.30 p.m., Lecture I:—Prof. W. D. Halliburton: Physiology and the Food Problem.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON), at the Lecture Theatre of the Medical School, King's College Hospital, Denmark Hill, S.E.

Course of Four Lectures on Malaria. Microscopic specimens and lantern slides will be shown at the two last lectures.

FRIDAY, Feb. 7th.—12 noon, Lecture II:—Col. Sir Ronald Ross, K.C.B., K.C.M.G., F.R.S. Officers and Men of the Royal Army Medical Corps are invited to attend.

ROYAL INSTITUTE OF PUBLIC HEALTH, in the Lecture Hall of the Institute, 37, Russell-square, W.C.

Course of Lectures and Discussions on Public Health Problems under War and After-war Conditions:—

WEDNESDAY, Feb. 5th.—4 p.m., Mr. W. Buckley: Practical Steps that should be taken to ensure a National Clean Milk Supply.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street Piccadilly, W.

FRIDAY, Feb. 7th.—5.30 p.m., Prof. J. G. Adams: Medical Research in its Relationship to the War.

BOOKS, ETC., RECEIVED.

LEA AND FEBIGER, Philadelphia and New York.

A Text-Book of Biology. By W. M. Smallwood, Ph.D. 3rd ed. 10s. 6d.

LIVINGSTONE, E. AND S., Edinburgh.

Hughes' Nerves of the Human Body. By C. R. Whittaker, F.R.C.S. Edin. 2nd ed. 3s. 6d.

MASSON ET CIE, Paris.

L'Expertise Mentale Militaire. Par A. Porot et A. Hespard. 4 fr.

Traité de Physiologie. Tome V. et dernier: Fonction de relation et fonction de reproduction. Par J. P. Morat, professeur à l'Université de Lyon, et M. Doyon, professeur adjoint à la Faculté de Médecine de Lyon. 25 fr.

MILFORD, HUMPHREY, London.

Destroyers and Other Verses. By Henry Head, M.D. 4s. 6d.

MURRAY, JOHN, London.

Handbook of Physiology. By W. D. Halliburton, M.D. 14th ed. 16s.

NATIONAL FOOD REFORM ASSOCIATION, London.

Dietaries Suitable for Secondary Schools, &c. By Dorothy C. Moore, L.C.A., and C. E. Hecht, M.C.A. 1s. 3d.

PANINI OFFICE, Allahabad.

Diabetes and its Dietetic Treatment. By B. D. Basu, Major, I.M.S., retired. Rs 1.8.

UNIVERSITY PRESS, Cambridge.

Technical Handbook of Oils, Fats, and Waxes. By P. J. Freyer, F.I.C., and F. E. Weston, B.Sc. Vol. II.

UNIVERSITY PRESS, Manchester. **LONGMANS, GREEN, AND CO.**, London.

Dreams and Primitive Culture. By W. H. R. Rivers, M.D. 1s.

Communications, Letters, &c., to the Editor have been received from—

A.—Dr. F. S. Arnold, Berkhamsted; Dr. J. E. Adams, Lond.; Prof. Ch. Achard, Paris; Messrs. Allen and Hanburys, Lond.

B.—Lieut.-Col. A. Balfour, C.M.G., R.A.M.C.; Major-Gen. Sir J. Rose Bradford, A.M.S.; Major-Gen. Sir Anthony Bowlby, K.C.M.G., K.C.V.O., C.B., A.M.S.; Surg.-Gen. R. Blue, Washington; Board of Agriculture and Fisheries, Lond.; Sir J. Bland-Sutton, Lond.

C.—Mr. A. L. Clarke, Lond.; Dr. J. B. Christopherson, Khartoum; College of Nursing, Lond., Sec. of; Dr. J. Campbell, R.A.M.C.; Sir James Cantlie, Lond.; Conjoint Board of Scientific Societies, Lond.

D.—Dr. F. W. Dobbin, Ballinacree; Mr. H. Dickinson, Lond.; Dr. A. Eichholz, Lond.

Notes, Short Comments, and Answers to Correspondents.

INDUSTRIAL UNREST AND THE NEW PUBLIC HEALTH.

At a meeting of the Royal Institute of Public Health on Jan. 22nd, at which Lord Moulton presided, Dr. I. Walker Hall, professor of pathology in the University of Bristol, delivered a lecture on Industrial Hygiene in Relation to War Strain and Technical Development. He started from the assumption that the events of the last four years had profoundly altered the enduring capacity of the people of this country, and it was more than possible that some of the present industrial unrest was due to this cause. The war had been responsible for various degenerations of the cardiac and vascular systems, for alterations in the pulmonary tissues, both directly as a result of chest wounds and inhalation of poison gas, and as a sequel to widespread epidemics. Trench fever and war nephritis had, in their turn, impaired the renal tissues. There would consequently be a considerable percentage of people unable to bear climatic change and fatigue. Mental strain, malaria, and venereal diseases were further factors to be taken into account, as well as the crippled condition of many whose wounds had healed. In view of these things we were, he said, faced by the need for a more rigorous application of hygiene in industrial life. Revision of the existing regulations might well be necessary, and as a beginning a routine attempt should be made at estimating the man's liability to fatigue and generally at defining the limits of physical endurance of working units. Medical officers of works would in future have to pay more attention to this side of their work than to therapeutic problems. Research would be necessary in regard to new industries which might bring in their train new industrial dangers and diseases. America had reported 32 new poisons in the preparation of munitions of war, and in the coming days of peace workers ought not to be subjected to the risks of such poisons until the conditions of their harmful action were definitely known. Proposals for increased production or lessened cost must always be considered alongside an estimate of the possible dangers to the health of the worker resulting from the change. New processes before being tried on a commercial scale should all be investigated in the laboratory, both in regard to possible ill effects on animal tissues and with a view to prevention of these ill effects. But when all this had been done the human factor still remained. It was here that legal provisions might fail and the only remedy might prove to be the conscientious discharge of his duties by the medical officer of the factory, who would in the coming years devote more of his time to the workers than to the works. On the data obtained from the experimental laboratory the doctor would be in a position to observe closely the danger stages in all industrial processes and to assess the precise value of precautionary measures. Professor Hall concluded by reminding his hearers that the habits of the working man, as of all of us, were formed in childhood, and while these habits might be modified or consolidated in school life, no education, however skilfully devised, could replace the teaching of the primary habits of body which should be taught in the home. The hygienic status of the worker was cradled in the training of the child. He looked to a great crusade directed towards raising the standards of home-life.

Lord Moulton agreed with the lecturer in tracing the ultimate value of an industrial population to early training in childhood, but he had found the chief hygienic difficulty of the last four years to lie in the technical character of the work rather than in the quality of the workmen. It was especially difficult to make working men appreciate the importance of hygienic rules to be observed by themselves or recognise that neglect of cleanliness might lead to illness and possible death. The colossal demand made on the worker by the chemical side of munitions work had not led, in his opinion, to any undue strain. To find evidence of overstrain it was rather to the mechanical side of munitions manufacture that attention should be turned. While competition was ever becoming keener the working classes themselves were likely to take care that the conditions of work did not become more trying. To those who were not content with their existing level and prospects an increasing temptation arose to over-exert themselves. The danger in the future was far greater to this exceptional class than to the ordinary worker, whose future was clouded rather by the danger of carelessness in health and manner of life.—Miss Anderson welcomed the lecturer's recognition that men and women were highly endowed agents rather than mere instruments in industry. The service rendered by warfare work to industrial organisation had already been proved.—Dr. T. M. Legge concurred with the lecturer in the desirability of investigating

processes technically in the laboratory before they were introduced into the works.—Dr. E. L. Collis remarked on the incompleteness of our medical knowledge of industrial life at the beginning of the war. In the past medical practice had dealt mainly with agricultural pursuits, the doctor living among his patients and knowing accurately their conditions of work and consequently the proper methods of treatment. Whatever medical knowledge a practitioner possessed he could not give the same useful advice to his industrial patients that his grandfather gave to his agricultural patients if he was totally unacquainted with their conditions of daily work. Here was an entirely new field of preventive medicine opening before them.

THE HYGIENIC REPAIR OF THE ROADS.

It has been freely stated that something like a sum of £40,000,000 will be required to restore to our roads, badly broken by heavy military traffic, a uniform surface. Our road authorities are, no doubt, seriously exercising their minds as to the best way this work of repair can be done. For the ordinary traffic of the country the dressing of the surface of roads with tar and grit seemed temporarily at least to suppress the dust nuisance created by fast motor vehicles. Such a dressing appeared to be a cheap and ready form of asphaltting the surface, and the way tar and grit subsequently set and hardened on the top suggested that a definite and unexpected combination took place. In a communication we have received from Dr. J. A. Calantar he points out also that the basic fault of roads treated in this way (except wood-paved ones) is that they are grouted with a very large proportion of whinstone sand, gravel, granite chips, and other earthy, gritty substances which in time get pulverised by traffic and give rise to dust and mud, and by this circumstance quickly wear away. His proposal is that all these earthy substances should be completely excluded from road surfaces, and in their place some fibrous substances, such as sawdust, should be used in combination with hot bitumen or pitch and creosote or other non-drying oil well amalgamated and laid on the roads, as ordinary asphalt is done. He points out that sawdust cannot be pulverised; it absorbs the hot bitumen or pitch and oil into its innermost fibres, which get matted together and when cold present a very hard, tough mass, which can neither be broken nor made into powder. Such a surface, he maintains, will be water-tight, not liable to decay, free from dust and mud, still be resilient, not cold to the feet, noiseless, and more durable than asphalted roads. The effects of traffic on such a surface are anticipated to make it, if possible, more dense, because the particles, being adhesive, will cohere together still more strongly under the pressure, instead of getting pulverised as the road surfaces are now. Such claims sound attractive, and if based on actual practical trials should receive the careful attention of our road authorities. Objection as to the contamination of rivers, streams, and lakes is urged, and a good deal turns on the question as to whether sawdust is available in anything like the quantities or the low prices that prevail for granite chippings.

COLONIAL HEALTH REPORTS.

Malta.—According to the Blue-book for the year 1917-18, the civil population on April 1st last was estimated at 224,323, an increase on the previous year of 582. The birth-rate for the year was 29.81 per 1000, and the death-rate 26.22 per 1000. The death-rate among children under 12 months was 293.51 per 1000 births, as against 253.80 in the previous year; that of children under 5 years was 128.35 per 1000 of the population at that age, as compared with 105.80 in the previous year. There were 1496 marriages, as compared with 1274 in the previous 12 months. Small outbreaks of enteric and measles occurred during the year, and a considerable epidemic of whooping-cough. There was also an increase in the number of cases of pulmonary tuberculosis. Apart from these circumstances, the general state of health of the two islands may be regarded as satisfactory. The number of goats and sheep found infected with undulant fever and destroyed was 287 out of a total of 5944 that were examined. 4011 persons were successfully vaccinated. The mean temperature for the year was 64.8, as compared with 66.3 in 1916-17. The total rainfall was 17.71 inches -1.98 more than in the previous year. The number of patients admitted into the hospitals of Malta and Gozo was 3610, and 148,116 persons were attended by the district medical officers at the Government dispensaries or at their own residences. The number of inmates in the leper hospital on March 31st, 1918, was 98, as against 114 at the end of the previous year. Since the last annual report, it has been found possible to dispense with many of the hospitals which had been opened to meet military requirements during the earlier stages of the war.

Croix de Guerre would be glad to know of a print or photograph of Saint Luke suitable for the centre light of a stained glass window to be erected in memory of a medical man.

A Lecture

ON

GIZZARDS AND COUNTERFEIT GIZZARDS

*Delivered at the Royal Society of Medicine on
Feb. 5th, 1919,*

BY SIR JOHN BLAND-SUTTON, F.R.C.S. ENG.,
SURGEON TO THE MIDDLESEX HOSPITAL.

IT is a simple lesson in anatomy to watch a cook gut a fowl, open the gizzard, wash out the stones, and after turning it inside out she skewers the gizzard under one wing and the liver under the other. The bird is then ready for the front of a fire or the inside of an oven. Boys who have watched the trussing of fowls learn from this simple lesson that cocks and hens are not always gathering grain when they diligently peck about the barn-yard. They pick up also small stones. An inquisitive boy asks: Why do birds swallow stones? and in this way learns the relationship between the absence of teeth in birds and the need of a gastric-mill for grinding the hard seeds they swallow.

STRUCTURE AND FUNCTION OF THE GIZZARD.

The stomach of most birds consists of a proventriculus, which is glandular, and the gizzard, or grinding portion, which has thick muscles and a hard lining. The muscularity of the gizzard and the thickness of its lining depend entirely on the nature of the food, in the same way that the skin covering the palm of the hand varies with occupation.

John Hunter experimented to find out the nature and use of the gizzard. The gull, a fish and flesh eater, has a thin-walled gizzard, but when fed on grain the walls thicken and the gizzard resembles that of a grain-eating bird. Hunter also noticed that when the gizzard is working the noise of the grinding can be heard if the ear be placed on the side of the fowl—a simple and curious lesson in auscultation. With

FIG. 1.—The gizzard of a turkey, showing the central tendon and its relation to the muscular bundles.

patience and care cocks and hens soon submit quietly to the examination. Under the X rays the movements of the small stones are easily seen, and without distress to the bird.

The grinding power of the gizzard in some birds is great, for the stones they swallow are polished like pebbles. Birds swallow hard bodies promiscuously. It is not uncommon to find in gizzards pieces of glass and crockery, pins, needles, hooks and eyes, and occasionally coins. Pointed pieces of

No. 4980

metal sometimes stick through the walls. Birds that live on fish often have the gizzard pierced with fish-bones. The bustard is a grand bird, and at one time common in England. The museum at Salisbury contains two stuffed bustards, reputed to be the last two examples shot on Salisbury Plain. When the gizzards were opened they contained, among other stones, some flint arrow-heads.

The gizzard of the ostrich is big and powerful; this bird shows little sense in selecting objects for swallowing, especially when confined in a menagerie—stones, glass, and glittering objects, especially coins, which it will snatch from the hands of children. William Hunter's collection at Glasgow contains the gizzard of an ostrich with a wooden peg 3 inches long sticking through a hole in its wall. This gizzard also contained pieces of a silver buckle. I found, among other odd things, 49 bronze coins and a fourpenny-bit in the gizzard of an ostrich that had long been in the Zoological Gardens, Regent's Park. The coins were smoothed and some were thinned and edged like knives. An ostrich in the menagerie at Clifton swallowed a Book of Common Prayer and died soon afterwards. Dr. Harrison examined the bird and found the remnants of the book. Nearly the whole of this Prayer Book had been destroyed, but the Thirty-nine Articles were intact; even an ostrich found them indigestible—too many and too much.

One of the most remarkable gizzards among birds is found in the snake-bird or darter; it has a third compartment, known as the pyloric bulb, that leads into the duodenum. (Fig. 4.) The bulb is beset with a thick fringe of hairs serving as an excellent strainer to hinder fish-bones entering the narrow intestine. Snake birds are voracious fish-eaters. Hairs are sometimes found on the walls of the cuckoo's gizzard, but they have a different origin.

HAIR BALLS.

The nature and direction of the movement of the stomach have occupied the attention of many physiologists. It is a matter of common observation that hairy animals lick their skins and swallow the hair, which is felt by the motion of the stomach and forms a ball. When such a ball is divided

FIG. 2.—Gizzard of a turkey in section, showing the thick muscular walls.

the hairs will be found to lie in the same direction. Hunter noted that this effect could only be produced by a regular motion of the stomach. He studied the arrangement of the fine hairs that are occasionally found in the gizzard of the cuckoo. In certain seasons this bird lives on the hairy caterpillars of the tiger moth known as woolly bears, and the hairs stick on the walls of the gizzard and acquire a regular spiral arrangement due to its rotatory motion.

F

FIG. 3.—Gizzard of a fowl, with stones *in situ*.

OAT-HAIR CONCRETIONS.

The Hunterian collection contains a number of concretions, irregular in form and of various sizes, found in the great intestine of men and women who lived for the most part in Scotland and the northern counties of England. These concretions, large examples of which may be as big as the fist, are dirty white or brown, smooth externally, and exceedingly light. On section they displayed concentric layers of a fibrous substance, felted, velvety to the touch, and with a foreign body, such as a piece of bone, or metal, or a fruit stone, for the nucleus (Fig. 5). Alexander Munro, sen., had in his collection 42 examples of such concretions, varying in size from a pea to masses 6 inches in circumference.

Oat-hair concretions puzzled many until their composition was detected by Wollaston. He found that they consisted for the most part of velvety vegetable fibres pointed at both ends, and this led him to suspect that the concretions arose from some kind of food peculiar to Scotland. Clift, the conservator of Hunter's museum, suggested to Wollaston that the fibres might come from oats, and on examining oats, the vegetable material of the concretions was found to be identical with the fine hair-like bodies within the husks. Portions of oat-husks and other vegetable fibres are found in the concretions, and it was definitely established that they chiefly occur in persons who live upon undressed oatmeal. A century ago oat-hair concretions were common in Scotland, but they are uncommon now, and this is probably due to improvements in dressing oatmeal and the decreased use of it as a food.

Oat-hair concretions occur in horses, usually in the cæcum and colon. The farrier calls them "dung-balls."

FIG. 5.—Oat-hair concretion in section.

Outside of the bird tribe there are animals with stomachs so modified as to resemble gizzards. The most remarkable are the gizzard trout, the grey mullet, the crocodile, and the ox.

COUNTERFEIT GIZZARDS.

The Gizzard Trout and Grey Mullet.

Hunter made a special study of the stomach of the gizzard trout and, as lawyers would say, he stated a case which is well worth consideration.

In the gillaroo trout, known in Ireland as the gizzard trout, a portion of the siphonal stomach is thick and muscular for crushing the shells of the freshwater molluscs on which it feeds. The stomach of this trout is more globular than that of most fishes, and endued with sufficient strength to break the shells of small molluscs, but it can scarcely possess any power of grinding as the whole cavity is lined with a fine villous coat.

The grey mullet (*Mugil*) has a stomach that approaches in structure and function very closely the gizzard of a grain-eating bird. This fish has feeble teeth and lives on minute organisms mixed with sand. The second portion of the stomach is globular and thick; the muscular tissue is arranged circularly and equal in thickness throughout, and the stomach has a thick lining.

Hunter came to the conclusion that neither the stomach of the gillaroo trout nor that of the grey mullet can be justly ranked as gizzards; they want "a power and motion fitting for grinding and a horny cuticle." His opinion reminds me of a considered legal judgment on a contentious case. The judge discusses the facts, but does not settle the matter.

It is not easy to frame a definition of a gizzard, and in order to show the difficulty it will be worth while to consider the counterfeit gizzards of crocodiles and oxen.

The Crocodile's Stomach.

In the beginning of winter 1764 Hunter got a crocodile 5 feet long that had been in a show several years before it

FIG. 4.—Gizzard of a snake-bird, open and showing the hairy strainer in the pyloric bulb. (Museum, Royal College of Surgeons.)

died. At that time crocodiles were rare in London. After making a careful examination of its viscera, he writes: "The crocodile comes nearest to the fowl in the structure of its internal parts of any animal I know. The stomach is of the gizzard kind and has a middle tendon on each side about the breadth of a shilling and all the fleshy fibres pass to it." The stomach of one he had from Jamaica contained the feathers of a bird and a few bones. There were stones in the stomach, some bigger than the end of a man's thumb, and seeds. The Hunterian Museum contains the skeleton of a crocodile shot in the Nile near Silsilis in 1877. The brute, which had been a terror to the natives of a long stretch of the valley, was 16 feet long and reputed to be 80 years old. The stomach contained three hoofs of a sheep or goat, a donkey's hoof, a donkey's bridle, and an ear-ring.

Kermit Roosevelt shot a large crocodile in British East Africa; in its stomach there were sticks, stones, the claw of a cheetah, the hoofs of an impalla, big bones of an eland, and the shell plates of a large river turtle.

A crocodile caught in fishing nets near Khartum lived for seven months in the Zoological Gardens, Cairo. The stomach contained two litres of quartz pebbles, fragments of the hoofs of an ungulate, and piece of water-worn bottle glass. (Shann.) Stones are invariably found in the stomachs of mummified crocodiles. The presence of stones in a stomach does not make it a gizzard, for pebbles are often present in large quantities in the stomachs of seals and sea-lions.

The Omasum of Ruminants.

If the capacity to grind is the first qualification of a gizzard, the nearest approach to one in mammals is that compartment of the complex stomach of ruminants known as the omasum.

The stomach of an ox consists of four compartments. The first is a large receptacle called the rumen; the second is a recess of the rumen and named, from its likeness to honeycomb, the reticulum; this when cleaned is the choicest kind of tripe. The third compartment, the omasum, is a dilatation of the passage between the reticulum and the fourth compartment, the abomasum, or rennet.

The omasum is curious and complex; it is in a full-grown ox of the same shape and as big as a bladder of lard; the walls are thick and muscular, and the mucous membrane is arranged in folds or leaves (Fig. 6); nearly a hundred leaves hang from its dome, stretching from the œsophageal opening to the entrance of the abomasum. These folds vary in width and produce an appearance like that of the flies of a theatre seen from the stage. The folds earned for the omasum the name of manyplies, and psalterium from its likeness to a book. Butchers call it the bible.

The omasum, like the gizzard, is a triturating organ and the details of its structure were described by Ellenberger (1881). The leaves near the entrance are beset with long papillæ resembling the teeth of a harrow, and hinder the reflux of food to the reticulum. Towards the abomasum the papillæ are shorter, closer set, and flattened, like the low elevations

FIG. 6.—Omasum of an ox in transverse section, showing the œsophageal opening and the disposition of the folds.

on a rasp or a file. The covering of the leaves is hard, almost horny, and resistant to dilute solutions of acids, alkalis, and peptic juices. The walls of the omasum

contract powerfully; grass and sodden hay from the rumen pass between the leaves and are thoroughly rasped by the papillæ before entering the abomasum, the true digestive compartment. The larger part of the ruminant's stomach is like a pocket, non-digestive.

The leaves of the omasum are occasionally transfixd by needles and pins. Hunter observed that this was common in cows feeding in the grass of bleaching fields, but he did not realise the gizzard-like action of the omasum.

In culinary art few things are meaner than a gizzard. It is only fit for a dog to eat, but to Hunter it furnished food for thought and became the subject of experiment. It has often happened that observations made on apparently common things in nature have led men to investigate some of the most profound problems of physics, of which life is the most complex manifestation.

POST-MORTEM DIGESTION OF THE STOMACH.

Why does the stomach not digest itself? Many have asked this question. John Hunter about 1772 discovered that the stomach sometimes digests itself after death. His first observation was made on a man who had been killed by one blow of a poker, after taking a hearty supper of cold meat, bread, cheese, and ale. The stomach was dissolved at the cardiac end and a considerable part of its contents lay loose in the general cavity of the belly. The second case occurred in a man who died after receiving a blow on the head which broke his skull. Hunter subsequently found another example in a man who had been hanged.

These observations led him to procure the stomachs of vast quantities of fishes whose deaths are always violent, and they are at the time in perfect health and usually with their stomachs full. In some instances a fish will swallow another fish and a part of it will be in the stomach and a part in the gullet. The part of the fish in the stomach will be dissolved, while the piece in the gullet remains sound. In many of the instances the digesting part of the stomach was itself reduced to the same dissolved state as the digested food. Then it struck him that the stomach, being dead, was no longer capable of resisting digestion.

FIG. 7.—The dory, *Zeus faber*, and the 15-spined stickleback.

Self-digestion of the stomach has been studied by pathologists. Modern experiments prove that gastric juice is only poured into the stomach when the material to be acted upon makes its appearance therein. When a person dies with the stomach empty it may be found several days after death unaltered. If there be food in the stomach and the digestion process in operation when the person dies, then on examining the organ a few hours after death its coats may be found destroyed, allowing the contents of the stomach to escape into the belly.

Animals which Swallow their Prey Alive.

Hunter's observations on post-mortem digestion of the stomach led him to experiment on digestion, and the "pursuit led him into an unbounded field." He discusses the probability of live animals being digested, and at once states, "no fresh proofs are necessary, as we eat oysters every day." This is no proof that they are digested alive.

Snakes sometimes swallow their prey alive. A girl whom I knew kept tame snakes as pets. One day she took a grass-snake and two tree-frogs in a basket to amuse her friends. On opening the basket she could only find one frog and the snake; but a bulge on the snake indicated its position, so she promptly cut off the snake's head and released the frog by a post-mortem celiotomy. The frog survived delivery. Here is another instance. Two boas, companions in the same cage in the Reptile House at the Zoological Gardens, London, seized the same rat at 6 P.M. These snakes were nearly of the same size. At 6 o'clock the following morning only one boa was visible, but the officer in charge saw the tail of a snake sticking out of the mouth of the boa. A keeper seized the tail of one snake; another keeper dragged on the tail of the snake that had been swallowed and gradually released it. An hour after extraction this boa took a rat on its own account and in good style. What would have happened to the incarcerated snake if it had not been delivered is not a matter for surmise: it would have been digested, as the following incident proves:—

Some 20 years ago a Madagascar boa swallowed a boa, its companion boa of nearly the same size, retained, and digested it. Two weeks later I made a search among the pebbles at the bottom of the cage in which the survivor lived and collected some of the vertebrae belonging to the victim. All the soft parts had been thoroughly cleaned in the process of digestion.

I have often thought that live animals, such as fishes, frogs, lizards, and chameleons, when swallowed by storks, bustards, shoebills, or secretary birds, must have an uncomfortable time in stomachs of their captors, and have pictured to myself the agony of being digested alive or slowly ground to death in a gizzard mill. At sunrise I watched some birds fishing in a swamp of the White Nile near Tewfikia. One of the men shot a marabou, and in its stomach I found seven cat-fishes each the size of a sprat. They were dead. The back of each had been broken by the powerful bill of the bird. It is a fair inference that many fishes swallowed by birds are either killed or paralysed before they reach the gizzard.

Fishes do not always kill the prey they swallow. A dory living in an aquarium with a 15-spined stickleback was bold enough, after some consideration, to swallow its spiny companion, and for a few seconds tried hard to bear the tickling; it was beyond his power and he vomited the stickleback, which seemed none the worse for the adventure. In recording this event, Hornell states that when the dory stalks a fish the coloured bands on his sides intensify and darken. The dorsal fin goes up and with a swift dash—the great telescopic mouth is thrown out—and the prey is gulped. (Fig. 7.)

The black mark on the side of the dory is, by fishermen of Roman Catholic countries, regarded as the mark of Peter's thumb when he seized the fish and "opened his mouth" to find the shekel wherewith to pay the tribute. (Matt. xvii. 27.) Those who believe this tale forget that the Sea of Galilee is a freshwater lake and the dory a salt-water fish.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on Feb. 3rd, Sir James Crichton-Browne, M.D., LL.D., F.R.S., treasurer and vice-president, in the chair. The chairman reported a bequest of £300 from the late Dr. T. Lambert Mears, who was a member of the institution for 53 years.

MEDICAL ASPECTS OF AVIATION.¹

By L. E. STAMM, B.A., B.Sc., M.D. LOND., R.A.F.

[AFTER taking a brief survey of the necessary physical qualities to meet the special conditions of stress and strain in the air, Dr. Stamm dealt with the mental qualities in more detail.]

Conscious Control of the Muscles.

We must first refer to the nerve mechanisms which subserve the mental functions. We have, in the first place, the sense organs of sight, hearing, and touch, also the muscular sense and sense of equilibrium. It is most essential that each one of these senses should function in a normal manner, and they are all tested in the course of medical examination.

In regard to the motor mechanism, it is important that the muscles show good tone and a power of nice control and adjustment. Deficiency in this respect is usually characterised by the pilot instructor as "heavy on controls." Such natural inherent clumsiness is a bad quality in a pilot, and means have been devised to test for this on the ground; but there is another deficiency which has not received much attention, but which I think is of some importance, and that is "conscious control of the muscles." A Mr. Matthias Alexander has developed the subject, and is disposed to ascribe all the ills of humanity to this lack of "conscious control." It is a fact, although it would be a surprise to most to learn it, that very few people have full conscious control of their muscles, and it can be demonstrated in this way: If a person is told to move a limb in any direction he will do so, but if he be told to relax the muscles of any limb so that you can move it in any direction he will probably not be able to do so, and the more you ask him to try to relax them the more rigid will the muscles become, while assuring you all the time that they are relaxed.

This inability to relax or inhibit muscular contraction shows a lack of conscious control of the motor mechanism, and is a factor of some importance for the pilot. It shows a lack of complete rapport between the muscles and the brain nerve centres that should control them. There is a great difference between individuals in this conscious control or lack of it. It is quite simple to test. The person is instructed to lie down on the floor and relax all the muscles of his limbs. One of the limbs is gently raised and then let go. If the limb is really relaxed it will, of course, drop at once, as if lifeless. If, however, as is often the case, the muscles are not relaxed, the limb remains in the air in the position to which it was raised. Some are so convinced that the muscles are relaxed that the limb remains in the air without its possessor realising the absurdity of the situation. Apart from the importance of the general principle of perfect rapport between brain and muscles, this unconscious rigidity may be responsible for a serious condition of things in the air in the course of training, as when a pupil loses his head and hangs on like grim death to the joy-stick, making it difficult or even impossible for the instructor to take proper control.

In my medical inspections of pupils at the aerodrome I used to test for this ability to relax and give directions for practice to obtain a proper control of the muscles and to be able to relax at will. I would suggest that some such instruction should be embodied in the ordinary physical training.

Mental Qualities.

In ordinary flying a pilot of any experience controls his machine automatically—that is to say, his sensations of sight, hearing, and touch giving him the necessary information about his machine are transmitted to the nerve centres, and the consequent muscular movements are carried out without any interference or control from the higher centres. But in the air circumstances are continually occurring calling for the exercise of the higher centres connected with decision, discrimination, judgment, in the most rapid and definite manner. At certain times rapid action following quick and right judgment decides his fate. Above all things, one requires for a good pilot a mental constitution that has the capacity to take in all the circumstances of a situation

¹ A paper read before the Royal Aeronautical Society at the Royal Society of Arts on Jan. 15th, 1919.

quickly and correctly and make a rapid and correct decision. When the engine conks the experienced pilot automatically puts the nose of the machine down and looks to his pressure gauge, and with his conscious mind looks around and takes in the conditions before him for a forced landing, and decides upon his course of action. For the inexperienced pilot some of the necessary actions, such as observation of pressure gauge, may not be automatic, so that there is still more to occupy the conscious mind.

For all this one requires not only a quick and accurate coördination between the senses and the muscles, but also between these and the higher mental functions.

A quick coordination between the senses and the muscles can be tested by taking the "simple reaction time," that is the interval of time that elapses between a person receiving a signal, either visual, auditory, or tactile, and his response to the signal, in the form of some movement, such as pressing an electric key. In my opinion, testing for this "simple reaction time" is of little or no practical value for the Air Service, because in healthy young men with normal senses and muscles the coordination between these and, therefore, the "reaction time" is sufficiently quick and accurate for all practical purposes, and in actual experience I have obtained some comparatively slow reactions from very capable individuals and very quick responses from some of poor mentality. In candidates for the Air Service I do not think these simple reaction time tests would eliminate 1 per cent. of undesirable.

What one requires to test is the ability of the candidate to respond quickly and accurately under conditions in which the higher *conscious* mental functions of discrimination, decision, and judgment are involved. For this purpose one has a number of different signals, requiring different responses, the candidate not knowing which signal to expect. This necessitates the intervention of the conscious mind between the perception of the signal and the motor response, and consequently the reaction time is lengthened. The mental ability is tested by the rapidity and accuracy of response in proportion to the complexity of the problem presented to the candidate.

Many forms of apparatus have been devised, but as the interval of time is only a fraction of a second and variations are measured in 1/100ths of a second some difficulty has been found in obtaining accurate and reliable apparatus that is also sufficiently simple for practical purposes. With the help of Major Burgess, engineer, R.A.F., I have devised an apparatus which is comparatively simple and which in practice has proved of value in testing candidates for the Air Service. A diagram of the apparatus is shown.

Reaction Time Apparatus.

It consists of a chronoscope, *A*, which registers to 1/100th second, and is worked electrically by a hammer, *B*, from a coil, *C*, and accumulators, *D*. There are four signals, two differently coloured lights, *E* and *F*, an electric horn, *G*, and an electric bell, *H*. The operator has a switchboard, *S*, by which any one of the signals is put in the current, and the signal is given by touching the key, *K*. The candidate sits opposite the operator and places his right-hand first finger on the brass plate, *P*, which is equivalent from the three keys, *K*₁, *K*₂, *K*₃. The end keys, *K*₁ and *K*₃, are for the corresponding lights, and the middle key, *K*₂, is for the horn or the bell. It was not considered desirable to complicate things to the extent of four keys.

When the operator presses his key, K , one of the signals is given, and at the same time the chronoscope starts. The candidate responds by touching the appropriate key, K_1 , K_2 , or K_3 , which stops the chronoscope, and the reaction time is read off in 1/100th seconds.

The method of examination is as follows. After a short preliminary rehearsal to acquaint the candidate with the method of working the apparatus, the candidate is tested for the simple "automatic reaction time" by one signal, which he knows beforehand. He is tested in this way by a series of each of the four signals. As already stated, I set no value on these tests, but they enable the candidate to get used to the apparatus. After testing for the simple reaction time with each separate signal the candidate is now told that he may get either one of the two lights, and he is to respond by touching the appropriate keys, K_1 or K_2 . Having done a series of ten with the two light signals, he is now given a series with three possible signals, the two lights and the horn, and finally a series of all four signals—two lights, horn and bell—but for the bell for which he has previously used the middle key, K_3 , he is now told to keep his finger on the brass plate. This involves mental inhibition. Each

series shows an increase in the reaction time, owing to the increased complexity of the problem before the candidate. Recently I have used a further series of four signals, in which the keys previously used for the lights, each corresponding to the light on the same side, are now reversed. This further complicates the problem and causes a further increase in the reaction time.

Diagrammatic Representation of the Reaction Time Apparatus.

The following are (1) the averages of 150 cases, including pupils and instructors (good pilots) and (2) of 20 instructors (experienced pilots), for the different tests in 1/100th seconds. The latter yield, as would be expected, appreciably lower figures:—

| | | |
|---|--------|------------|
| (1) Simple visual reaction (one signal) | | (28 ... 27 |
| (2) " auditory " | " .. . | " .. 25 |
| (3) Two signal test (two lights) | " .. . | " .. 35 |
| (4) Three " (two lights and horn) | " .. . | " .. 38 |
| (5) Four " (two lights and two sound signals) | " .. . | " .. 44 |
| (6) " (with keys to lights crossed) | " .. . | " .. 48 |

Taking the last two tests as the crucial tests of the mentality of the pupil, I have found a remarkable correspondence between the results and their capacities as flying pupils. Having tested a certain batch of pupils, I send the names to their instructors and ask for their opinion as to their flying capacities and possibilities of making good pilots. Arranging them in the order of the results from the machine, as a general rule the top names have "very good" or "good" against them, the middle ones "fair" or "average," and the bottom ones "poor" and probably "turned down" or sent to "heavier machines."

Appended is a list of pupils examined, with the results of the test and the criticisms of their instructors, from which the value of the test can in some measure be estimated.

I should point out that with my apparatus there is a muscular adjustment involved in the movement of the fingers to the different keys. In my opinion this is a valuable factor as a further test to the nerve mechanism, but it necessarily prolongs the reaction time, so that even the simple reaction time with my apparatus is longer than the usual without such muscular adjustment. It is quite easy to dispense with this for simple reaction to one signal by placing the finger ready on the key.

The Value of the Tests.

The value of the tests lies in the fact that they involve considerable adjustment and coordination between the senses and the muscles and at the same time call for a rapid and accurate working of the higher mental functions of conscious discrimination and decision, a complexity of conditions similar to that involved in piloting an aeroplane. Moreover, it calls for a prolonged effort of attention, and the ability to sustain the effort is shown by the way in which the candidate succeeds in keeping up his rate of response to the end of the tests or shows evidence of mental fatigue by sudden lengthening of the time intervals or by mistakes in the keys.

Table showing the Results of the Test, together with the Remarks of M.O. and Instructor.

| FLIGHT GROUP No. I. | | |
|----------------------|----------------------------|---|
| No. | 4-signal test in 1/10 sec. | Remarks of M.O. Instructor's remarks. |
| 1 | 31 | Haphazard, W. 7. Good, lacks judgment. |
| 2 | 35 | Very intelligent and quick. Very good—now instructor. |
| 3 | 35.5 | * 120. Nervy, guts mentally. Fair—nervy, drinks too much. |
| 4 | 36 | Sturdy, sports, W. 3. Good but slow. |
| 5 | 38 | Sturdy Canadian, horse-riding. Good, quick, guts. |
| 6 | 39.5 | Average. |
| 7 | 39.5 | All there—guts. Good—plenty of guts. |
| 8 | 39.5 | Says up-et by 3 instructors. Poor, no guts, gets sick. |
| 9 | 40 | No nerve physique. Average. |
| 10 | 41 | — Very good; steady. |
| 11 | 42 | — Good. |
| 12 | 42 | Capable, good type. Extra good. |
| 13 | 42 | Average. |
| 14 | 42 | Alert, good type. Very good—now instructor. |
| 15 | 42 | — Average, just started flying. |
| 16 | 43 | Intelligent. Good. |
| 17 | 43.5 | Sports, average intelligence. Fair—guts. |
| 18 | 44 | — Average. |
| 19 | 44.5 | Uptake slow. Good but silly. |
| 20 | 44.5 | Lethargic. Slow but solid. |
| 21 | 46 | Dumpy. Average, slow. |
| 22 | 46 | Musical, nervy. Fair. |
| 23 | 46 | Slow uptake, no sports, clerk. Average. |
| 24 | 47 | slow uptake, no sports, clerk. Average, slow learning. |
| 25 | 47 | Mert—sports. Good. |
| 26 | 47 | Nervy. Poor—windy. |
| 27 | 47.5 | Very anxious, W. 4. Average, persevering. |
| 28 | 48 | — Poor, sent to heavier machines. |
| 29 | 49 | Windy, paralysed by horn signal, bad type. Poor—windy. |
| 30 | 50 | — Average, large flying experience. |
| 31 | 50.5 | Bank clerk, not robust. Average. |
| 32 | 50.5 | Bright; guts. Good—lots of guts. |
| 33 | 50.5 | — Poor. ? Windy. To be turned down. |
| 34 | 52 | Slow but good type. Slow, but will make good. |
| 35 | 52 | — Fair. |
| 36 | 52 | Sturdy—rough and ready. Fair—solid—heavy-handed. |
| 37 | 52.5 | Slow and dull. Average to poor. |
| 38 | 53 | Nervy, sick on stunting. Poor. |
| 39 | 55 | Heavy—dull. Poor, sent to heavier machines. |
| 40 | 55.5 | Dull and windy. Poor, sent to heavier machines. |
| 41 | 57 | — Poor. |
| 42 | 75.5 | Mentality very poor. Hopeless. |
| FLIGHT GROUP No. II. | | |
| 43 | 33 | Journalist, M.A. Alert, no sport. Good: previous flying experience. |
| 44 | 36.5 | Average. Good. |
| 45 | 37 | Good type. Very good. |
| 46 | 37.5 | — Good—guts—keen. |
| 47 | 39 | Good type, Canadian. Very good. |
| 48 | 40 | Good type. Good. |
| 49 | 40 | Average. Good. |
| 50 | 40 | Quick but bumptious and over-confident. Good but objectionable. |
| 51 | 40.5 | Average. |
| 52 | 40.5 | Heavy Scotch type—guts. Average, perseveres. |
| 53 | 41 | Good type. Very good—now instructor. |
| 54 | 41 | — Good. |
| 55 | 41.5 | Average. Good, slow learning. |
| 56 | 41.5 | Bright and intelligent; guts. Very good and keen. |
| 57 | 41.5 | Accountant; lethargic, heavy. Heavy handed; to be turned down. |
| 58 | 41.5 | Lack of muscular adjustment. Poor and slow. |
| 59 | 42 | Good type—sport. Very good, steady and keen. |
| 60 | 43 | ? Windy. Good but windy. |
| 61 | 43 | — Average, rather slow. |
| 62 | 43 | M.C. Good but slow learning. |
| 63 | 43.5 | Heavy. Good but slow learning. |
| 64 | 44 | — Keen, lacks judgment, windy. |
| 65 | 44.5 | Nervous temperament, not windy. Average, keen, guts. |
| 66 | 44.5 | Sports, horse-riding. Average, keen, guts. |
| 67 | 45.5 | — Average but slow. |
| 68 | 46 | Good type. Good. |
| 69 | 46.5 | Good type, Canadian. Good. |
| 70 | 47 | Average. Good and very keen. |
| 71 | 47 | — Average to poor. |
| 72 | 48 | Little stamina, clerk. Average. |
| 73 | 48 | Average—no sports. Average. |
| 74 | 48 | M.C., slow. Good guts—slow learning. |
| 75 | 52.5 | P. 96. Tremors, ? windy. Average—windy. |
| 76 | 49.5 | Average. Slow—improving. |
| 77 | 50.5 | Nervy. Poor—windy. |
| 78 | 51 | Sports. Poor but guts. |
| 79 | 53 | M.C., not good type. Very slow; to be sent to heavier machines. |
| 80 | 53.5 | — Average. |
| 81 | 54.5 | M.C., heavy. W. 5. Hopeless, turned down. |
| 82 | 54.5 | M.C., heavy. Poor—very slow. |
| 83 | 54.5 | M.A., right. W. 4. Average. |

| 136 | 63 | Poor type. | Average to poor. |
| 137 | 63 | — | Average. |
| 138 | 66 | Slow but sturdy, horse-riding. | Average to poor, very slow. |
| 139 | 68 | Charterhouse School, but slow, heavy. | Poor—very slow. |

W. = mistakes in keys. M. = mentality. A, good. B, average. O, poor. Where not stated mentality is average.

Over and above everything else there is the "will" factor to be taken into account. This may act in at least two different ways. It may be negative. Then the results of the tests will not represent the best that the candidate can do. Or it may be very positive. It may be exercised to such an extent that the candidate exceeds for a time his normal power of reaction. In this case the excess of his efforts usually shows itself by mental fatigue setting in before the tests are finished, and he is unable to keep up the pace he has set for himself. All these variations are very useful to observe in forming an estimate of the candidate's mental constitution and capacity.

I would, in fact, claim for the apparatus that it not only gives figures of some value for estimating the mental capacity of a candidate for aviation, but that it affords a means of employing a candidate in a way which gives considerable opportunity of making mental notes in regard to his intelligence and personality, by the manner in which he tackles the machine. Some tumble to the game at once and show a remarkably quick adaptability, whereas others are equally slow in picking up the idea, but may warm up as one proceeds and give quite a good account of themselves in the final tests. Some are light in touch and accurate; others heavy and clumsy, so that they often miss the keys and almost break them when they touch them. I have myself been surprised in dealing with pilots personally known to me to observe how the machine seems to bring out and record their personality, and especially their flying personality. There appear to be two good but different types of mentality which react differently to the apparatus. In the one the reaction times are very quick, but in cutting down the time allowed for discrimination to the utmost in the final tests several mistakes may be made. In the other good type the

reaction times are appreciably longer, perhaps even above the average, but the signals are responded to with absolute accuracy. The flashy, crack scout pilot shows the first type of reaction, while the steady careful pilot is characterised by the second type of reaction.

Any flying man may say, "These tests may be very good, but even if a man has ever such quick discrimination and judgment he is no use as a pilot unless he has guts." This brings us to the second important mental factor—the emotional.

Emotional Stability.

We can distinguish two extreme types—one in which disturbance of these centres, by some emotion, whether that of fear, anger, sorrow, or joy, causes a most profound effect upon the rest of the nervous system, resulting in rapid heart action and other disturbances of the circulatory system, rapid respiration or temporary stoppage of same, tremors of the muscles, and an upset of the digestive system; and all this bodily disturbance may be accompanied by an inhibitory effect upon the higher nerve centres, so that the processes of thought, judgment, discrimination, and action are paralysed. In such a type it does not matter a straw whether under normal conditions the individual can think, decide, and act quickly or slowly, because when he is emotionally disturbed by, say, impending danger his mental processes are paralysed and his bodily functions are so disorganised that his machinery is out of control. In the other type the emotional centres are so stable that no such disturbances to the rest of the machinery take place, even under the most trying conditions. There may be, and almost certainly is, some activity of these emotional centres set up, but this results in a stimulation of the rest of the mechanism, so that his powers of thought and action are actually increased.

One has here a striking analogy between the effect of the emotional centres upon the rest of the nervous system and that of drugs; all drugs such as alcohol, opium, and the anaesthetics that have the power of affecting specially the nervous system first stimulate it to greater activity and then paralyse it. If the dose is small the effect is chiefly that of stimulation, and the period of stimulation may be of some duration, but if it be large the period of stimulation is very short or non-existent, and the chief effect is that of paralysis. The difference in emotional effect is again exemplified in artistic performers. In some the emotional disturbance of fear is so great that they are unable to perform in public. In others the emotion serves as a stimulus to help them to do their best.

It is obvious that the individual who is liable to such serious emotional disturbances or, in the language of the Service, liable to get the "wind up," is constitutionally unfitted for work in the air. And here I would point out that such a person is not necessarily a coward in the ordinary acceptance of the term. The condition is constitutional. He may have the mental "guts," the will-power to force himself to incur any risks. He may have proved himself an excellent infantry officer and go into the Air Service with all the desire and determination to win laurels by bringing down Huns in the air, but when he finds himself in the position of danger that he has voluntarily incurred he is handicapped by these emotional disturbances and is not likely to do the best for himself.

Tests for the Emotional Factor.

There are, of course, many intermediary conditions between the extreme types I have depicted, with a certain average, but it is most important that we should be able to eliminate at least individuals in whom the tendency to severe emotional disturbance is likely to manifest itself. Various tests have been devised, the principle of which consists in trying to arouse the emotion of fear by some sudden and alarming noise, such as a pistol shot, and testing the bodily reactions, such as increased heart action, muscular tremors, &c. The artificiality of the conditions somewhat vitiates the results.

I have found that the pulse-rate under ordinary medical examination is a very fair guide to detect the "windy" type. People who manifest their uneasiness at coming before a doctor for examination by a rapid pulse, which does not settle down in spite of every effort to put them at their ease, prove by that fact that there is a lack of control of the nerve mechanism of the vital centres, that there is an instability and liability to serious disturbances by the emotion

of fear, and they belong to the "windy" type. This instability does not appear to be in the vital centres themselves, but in the higher nerve centres controlling them, because such individuals respond to the ordinary physical test in a normal manner. The manometer test, the exercise test, show a perfectly normal acting mechanism; it is the rapid pulse of emotional disturbance.

Then there is a typical facial expression which one gets well acquainted with in carrying on this work. It consists in a furtive, apprehensive look, as if always expecting something unpleasant to happen, with a certain look of indecision and uncertainty, in marked contrast to the straight, direct, decided expression of the crack fighting pilot. One cannot say that an amount of "windiness" above the normal may not be present without this obvious expression, but when it is well marked I should have no hesitation in throwing its possessor out as undesirable for the Air Service.

It has been found that the bodily expression of an emotion owing to the disturbances in the circulatory system causes a deflection of a sensitive galvanometer proportional to the disturbance, so that this would appear to offer a means of comparing the extent of emotional instability in different persons. The chief difficulty lies in artificially producing the conditions necessary for calling forth the emotion. To some extent my apparatus is a test of an emotionally nervous instability, because in a highly nervous person the ideal of being examined in this way tends to set a condition of stage fright, and I have had cases in which the startling noise of the horn has shown a paralysing effect by causing a pronounced lengthening of the reaction time to this signal as compared with the other signals. But the apparatus is by no means a satisfactory test for the emotional factor, for in actual practice this emotional factor has been the chief disturbing influence in the results of these tests; pupils giving good results with the apparatus may be marked "poor" by the instructor because they are "windy," and others showing long reaction times may be marked "good" by their instructor because they have "guts"! Very frequently, however, I have also detected these qualities by the tests I have referred to and made notes to the same effect.

Essential Mental Qualities for Aviation.

We have, then, these two chief mental qualities—quick, accurate judgment and an emotional stability or "guts," or, to use the term in a general sense, "confidence." Now, although instructors lay so much stress upon the "guts" of a pupil, disregarding to some extent the intelligent factor and judgment, in my opinion one requires a nice balance between the two. Crashes occur from two chief causes: (1) "wind up" or "losing one's head," due to loss of control from emotional disturbance of fear in the manner already described; (2) over-confidence in an intelligence or judgment which is below the average and which therefore does not justify the confidence.

The one condition is quite as responsible for disasters as the other. I have cases on record that have given poor results with my apparatus, and of whom I have formed an adverse opinion on account of lack of intelligence on general grounds, education, &c., but who have been marked "good" by the instructor because they have "lots of guts." The verdict of my apparatus has been in the end justified, because the inevitable crash has come. Above all things it is necessary that a man should know his own limitations as well as those of his machine.

It must be admitted that when we have picked out these two important factors of "judgment" and "confidence" and applied our tests for them we have not exhausted the whole subject of mentality. There still remains the general temperament and mental constitution, though these are largely made up of varying degrees of these two functions. We have in any case no further tests, physical or otherwise, that we can apply to discriminate between the various types.

This power of judgment and quick decision does not appear to involve the highest intellectual functions of the mind; it is rather on a par with what we call "tact" in ordinary life. It is the power quickly to take in all the circumstances of a given position and react to it in the best manner—to do the right thing instead of the wrong with quick decision. There is a certain type of highly intellectual person who would by no means take first prize at the tests with my apparatus, but also he would not make a good pilot.

While one may in this way pick out special mental characteristics essential for the successful aviator and exclude anyone specially deficient in any one of them from air service, one must at the same time recognise that there is an infinite variety in the temperaments and mental constitutions of men, and that therefore no hard-and-fast line can be drawn. Just as there are many types of aeroplanes, each more or less useful for a particular purpose and in each of which the designer has had to compromise between the lift and the drift or the speed and the climb, so the pilot of cool judgment, though somewhat slow and deliberate in action, is suited for one service, while the quick, high-spirited, though somewhat emotional, erratic type may be chosen for another, such as the fighting scout. In both cases they may be a compromise in comparison with the ideal pilot.

Aviation requires, above all things, a strong, tough nervous system that can withstand all the stresses and strains, both mental and physical, in the air, that controls well the vital organs, reacts to external conditions quickly and accurately, and is not affected detrimentally by emotional disturbances. Just as one uses the term "physique" to the general development of the body and one speaks of good or bad "physique," so I would suggest the expression "nerve physique" to describe the general tone of the nervous system. There is a general consensus of opinion that a good "nerve physique" is found in young men who have led an outdoor life. Outdoor pursuits not only tend to develop such a nerve physique, but also offer in many ways the best training for aviation by developing their power of observation and quick response, as in the case of riding, shooting, hunting, and, though perhaps in a less degree, almost any sport.

The Fighting Spirit.

It has been suggested that the best type of fighting scout must possess the fighting spirit and be capable of developing the emotion of anger with his foe—in other words, must be able "to see red." With this I disagree. In conformity with what I have already said in regard to the emotions, it is my firm conviction that a pilot requires to be as free as possible from any emotional disturbance, whether of fear or anger, and that if he "sees red" his judgment is liable to be clouded and faulty. I must admit that this is to some extent an armchair opinion, but I have sat in a machine taking part in a scrap many times, and I think I have sufficient imagination to fill in the rest of the picture; and as it appears to me, the fighting scout requires the hunting instinct, with all the judgment, cunning, and zest to down his prey, rather than the fighting spirit of "seeing red." It is the man who goes forth in this spirit, aggressive but cool, that is most likely to carry through those nice turns and twists in the right direction and at the right moment that seal the fate of his adversary and render him the victory.

Alcohol and Tobacco.

Then there is the much-voiced question of alcohol and tobacco. From what I have already said it will be obvious that it is not only necessary for the pilot to possess a good nerve physique, but to keep it up to pitch, and any excess reacts deleteriously upon the nervous system more than on any other part of the body, more especially excesses in drugs such as alcohol and tobacco. Nothing will better contribute to the restriction of these than the ample provision of facilities for out-of-door sports. More especially I would plead for the provision of horse-riding, both for pilots and pupils under instruction. Horse-riding is one of the best physical exercises, and probably comes nearer to controlling an aeroplane than any other ground occupation. I would suggest that every aerodrome should have its stables as well as its hangars, and what better place than an aerodrome for polo? Furthermore, there is a much greater inclination to indulgence as a means of combating conditions of stress or "staleness" from long service. In my opinion no one should be engaged in continual flying, whether as instructor, ferry pilot, or on active service, for more than three months without a complete rest of at least a couple of weeks.

WATER-SUPPLY OF KARACHI.—The President of the Karachi municipality states that ample supplies of water are now available and that the new wells provide a reserve of supply up to twice the consumption even of the period immediately preceding the monsoon.

SOME SIMPLE TESTS OF PHYSICAL EFFICIENCY.¹

By MARTIN FLACK, C.B.E., M.B., B.Ch. Oxon.,
LIEUTENANT-COLONEL, R.A.F.M.S.

I WISH to bring to notice some quite simple tests which I believe will be of use in determining the physical efficiency of an individual. I am approaching this problem from the point of view of a physiologist, and the tests have been devised to show the physical condition, not particularly of any one system, but rather of the individual as a whole.

The procedure has been to select for examination, as far as possible, healthy controls. In this connexion officers of the R.A.F., who have made good and who have been chosen by their commanding officers for their efficiency in flying and in fighting, have been examined and standards have been set, provisionally of course, and may have to be altered. On the other hand, a number of officers who have broken down for some reason or other have also been examined, and the results obtained compared with these healthy controls.

I would like to emphasise that these tests are not designed to supplant the work of the clinician in any way, and when a man is reported as physically unfit on these tests it does not mean that the work of the physician is finished, but that it is beginning. If the subject does not come up to the standards on being overhauled by the applied physiologist, then the psychologist, neurologist, cardiologist, or general physician will find something is wrong with him. These tests give indications for such overhaul.

The chief point in connexion with these tests is the technique. This is important because, if adopted, it is essential that all the tests be carried out in the same way on all occasions, so that various medical officers may apply them to the same individual at different times. It has been suggested in regard to the care of officers in the R.A.F. that preventive treatment is best. If officers were periodically subjected to these tests by medical officers at different stations they would carry with them a certain definite amount of information as to their physical condition at the time of the various examinations.

Description of Tests.

The first test is the *response of the pulse to exercise*.

It is of importance the way this is done. I would point out that there is no limit to the number of times a man may be asked to stand upon a chair, but the technique here suggested is suitable to the examination of a large number of subjects. The test is that a man shall lift his body weight through a definite height five times in 15 seconds. The rate of increase in the pulse as a result of the exercise is noted and the rate of return to the normal, the pulse having been taken standing immediately before the exercise. In this way uniformity of observation is obtained. Hitherto, if ten medical officers were examining candidates, some might order the candidates to touch their toes four times: the enthusiastic man would do so in 5 seconds, the lethargic man in 20 seconds. The test as devised is an effort to set a level basis for all candidates. Preferably the sitting rate of the pulse is first taken. The pulse-rate is then taken standing. If the rate is unsteady it should be counted in periods of 5 seconds until a steady rate is obtained.

The candidate is then put through a regulated exercise, which should be carried out as follows: Standing before a chair, he places one foot upon the seat of the chair and steadily raises his whole body to the height of the seat five times in 15 seconds, one foot being retained on the chair throughout. The examiner should regulate the speed and rhythm in the following way: Standing beside the candidate, holding the wrist, with his fingers on the pulse, the examiner swings the arm forward and backward to indicate the time of raising and lowering the body.

The subject still standing, the examiner then counts the pulse in 5-second intervals, and notes the acceleration and the time taken to return to the previous rate. In a good subject the increase of rate is about 20 and the time of return to normal 15-25 seconds. If the time of return exceeds 30 seconds it is suggestive of cardio-vascular inefficiency.

The breath-holding test.—Test No. 2 is quite simple, and consists in getting the subject to hold his breath without any preliminary deep breaths.

¹ A synopsis of a paper read before the Epidemiology and State Medicine Section of the Royal Society of Medicine on Jan. 10th, 1919.

I would insist upon the actual lines on which the test is laid down being followed: A deep expiration followed by the filling of the lungs, clipping the nose, holding the breath as long as possible. The significance of the test should not be mentioned to the subject. He should just be told to breathe out and breathe in as far as possible and then to hold the breath. At the end of the test the question should be asked as to what are the sensations experienced by the subject during the holding of the breath.

The test was originally designed to show whether there was oxygen want, and I still believe the test does show the subject who would suffer from oxygen want. From my experience I found that people who were likely to suffer from "oxygen want" would give up after a very short time in holding the breath and would almost invariably return an abnormal answer. A normal answer would be that the subject "had to give up," "felt he would burst," an abnormal answer that the "blood rushed to the head," "things became blurred," &c. The test, however, has other significance. The man without resolution, for example, will give up early.

As originally shown by Dr. Leonard Hill and myself, if a man who had held his breath in this manner then takes a lungful of oxygen instead of a lungful of air, the time of holding the breath will be increased from $1\frac{1}{2}$ to $2\frac{1}{2}$ times as long. Therefore what one breaks down from is, in the first case, oxygen want, because when one breaks down in holding the breath on oxygen the symptoms are quite different, and are those due to CO_2 excess—headache, sweating, &c.

Another interesting point in this connexion is this: It is known that the power to hold the breath is greatly diminished at altitudes. Therefore a man who can hold his breath a long time at ground level without discomfort has greater room for diminution in his power to hold his breath than a man who can hold his breath a short time at ground level before discomfort occurs. An efficient man at altitudes is a deep breather, whereas the man who is inefficient is a panter. Figures in regard to holding the breath were worked out in the first instance on 40 successful pilots, all picked out by squadron commanders, or by the Admiralty, or the R.F.C. as being quite able. The time the breath is held averages about 69 seconds and the sensations experienced normal. The vital capacity averages at 3800 c.cm., with a minimum of 3400 c.cm. in efficient fliers. In a number who were sent up for medical boarding the breath was held for not more than 45 seconds, usually much under, and in most cases the answers recorded were not normal.

The deduction, then, is that the breath-holding test on an individual would be an idea as to whether he was likely to do well in the air. As the results appeared to show that poor breath-holders could not last in the air, the breath-holding test was adopted at the R.A.F. Commissions Board. In my opinion it is preventing people going into the Air Force who would not do well. The question of "oxygen want" is a matter for serious future research, and in peace-time one will be able to do such research on a more scientific basis.

The third test is a combination of the first two tests.

Having got the pulse response to exercise and the time of the breath holding test, then the time the breath can be held after exercise can be taken. In the unfit the breath-holding power comes right down, probably by 30 seconds. The fit man may possibly hold his breath almost as long as before, but will not have a fall of more than 20 seconds. The man out of condition gives a big fall in time after exercise.

The standard for admission for the ordinary breath-holding test was set at 45 seconds. Under 45 seconds should cause the subject to be looked upon with suspicion, and probably graded in regard to the height to which he should go.

The vital capacity of pilots—The minimum in the table of successful flying officers is 3400 c.cm.

I suggest that the use of a modified gas-meter is the best way of measuring vital capacity, and preferably one made by an English firm; this has the great advantage over the German model, from which it was copied, that its capacity cannot easily be overshoot. Among officers who had broken down a great number of those tested were under the minimum of 3400 c.cm., but it was subsequently found that this was due to flying stress, some having a vital capacity of only 2800 c.cm.

Captain H. C. Bazett, M.C., R.A.F.M.S., has shown that in addition to these tests, if the respiration-rate is multiplied by the ventilation per minute and divided by the vital capacity, it is a very good indication of the power of a pilot to fly. A figure below 30 is good, a figure above 30 poor. A test like this will be of value for the selection of the high flier.

U tube tests.—The apparatus for the next test I wish to describe is a U tube manometer filled with mercury, with the scale moveable.

The test is a measure of the tone of the abdominal wall. The subject is asked to blow up steadily the mercury column as high as possible. The number of mm. Hg blown is recorded. If for any reason it is suspected that the subject is not trying, he is asked to try again with the scale of the manometer turned away. There should be but little difference from the previous reading, and in such a case encouragement may cause the subject easily to surpass his previous effort. He is then asked to try again while looking at the column. If he is not trying he will surpass his first effort, which he saw.

The sixth test is another test with the U tube manometer. This test is performed as follows:—

The subject is asked to empty the lungs, fill up, blow the mercury to the height of 40 mm. and hold it there, without breathing, for as long as possible. The nose should be clipped. A valuable adjunct to this test is the behaviour of the pulse during the time the mercury is being sustained. It is counted during each period of 5 seconds that the mercury is sustained. Starting at the 5th second in the normal individual there is generally a slow, steady rise in the rate of the pulse or a fairly marked rise which is sustained most of the time. For example, the pulse-rate may rise gradually from 72 to 96 or 108, according to the time the breath is held, or it may rise at once from 72 to 96 or 108 and be sustained there. A large rise in rate—e.g., from 72 to 132 or 144—is unsatisfactory. In cases of flying stress a characteristic response is for the pulse to jump up to a quick rate during the 5th to the 10th or 15th second and then to fall away in rate to normal or even below. Such a response is as follows:—

Normal at start, 84; 5th–10th second, 144 (sometimes almost impalpable); falling away (say 20–25 seconds) to 72 or even 60. Such cardiomotor instability is frequently associated with flying stress and is indicative of a need of rest. In any case the subject is generally not in a condition to be allowed to continue to fly. Other points in the examination should, however, be taken into consideration.

The averages obtained for these tests from some selected flying officers were:—

Expiratory force 112 mm. Hg.
Mercury held 52 sec.

It is suggested that they should all conform to the minimum standard, and preferably to the average standard.

Results of Tests in Successful Pilots.

Table I. gives a synopsis of results obtained from various sources.

TABLE I.

| Subjects. | Number examined. | Breath held. | Vital capacity. | Supplemental air. | Expiratory force. | Sustaining 40 mm. Hg. |
|---|------------------|--------------|-----------------|-------------------|-------------------|-----------------------|
| | | sec. | c.cm. | c.cm. | mm. Hg. | sec. |
| Fit instructors... .. | 22 | 67* | 4082 | 1620 | 112 | 52 |
| Iditto | — | 46† | 3300 | 1000 | 80 | 43 |
| Home Defence pilots | 24 | 72 | 3940 | 1496 | 119 | 50 |
| British candidates | 23 | 69 | 3823 | 1590 | 106 | 52 |
| U.S. candidates | 7 | 66 | 3814 | 1386 | 116·4 | 53·5 |
| Delivery and test pilots | 10 | 57 | 3620 | 1050 | 108 | 40 |
| Pilots returned for rest | 17 | 57 | 3897 | 1423 | 95 | 40 |
| Pilots training for scouts | 15 | 62 | 3820 | 1433 | 96 | 49 |
| Pilots taken off flying through stress | 27 | 49 | 3480 | 1134 | 74 | 25 |

* Average.

† Minimum.

One or two suffering from stress are included among the Home Defence and test pilots.

Practically all the cases examined in hospital fell below the standard. There was one very interesting case, who came with a letter to the hospital and was examined. I told him he seemed very fit, and on reading the letter afterwards found he was still doing very good service in France and had not really come for treatment to the hospital, but for special examination on account of his fitness and meritorious flying service. Another was a one-eyed man, whose only disability was that he was nearly blind in one eye. I could find nothing wrong by these tests. Many other instances could be given.

Results of Tests in Rejected Men.

Having found standards from the examination of successful pilots, I went to the Commissions Board and examined a number of rejects as the result of the routine examination there. The results are appended in Table II.

It will be seen that except one man, who was unfit on the vital capacity test, every man was rejected by the fatigue

TABLE II.

| No. | Age. | Breath held. sec. | Vital capacity. c. cm. | Supple- mental air. c. cm. | Expira- tory force. mm. Hg. | Sustaining 40 mm. Hg. sec. | Remarks. |
|---------|------|----------------------|------------------------------|----------------------------------|--------------------------------------|----------------------------------|---|
| 1 | 17½ | 55 | 4200 | 1300 | 80 | 42 | Rejected. |
| 2 | 17½ | 84 | 4300 | 1800 | 60 | 25 | " |

test. Some of these were people whom the medical officer was in doubt about and had sent them for examination, saying he had to pass them fit, but did not like the look of them, though he could see nothing wrong with them.

Importance of Using Tests in Combination.

I do not suggest that any one test should be taken in examining a candidate, but that they should be used in combination, and the instructions are that they should be used by the assessor for his guidance.

The results obtained by Lieutenant-Colonel J. L. Birley from pilots who had been fighting for several months and were being sent home for a rest support the results obtained by the U tube test. These pilots were fairly up to the average standard. On the other hand, cases who had been concussed were below average. One has here, therefore, a valuable test for the effect of crashes.

Lieutenant-Colonel Birley obtained from these found permanently unfit for flying the following results:—

| | |
|--------------------------|------------|
| Average expiratory force | 76 mm. Hg. |
| Sustaining 40 mm. Hg. | 28 sec. |

As I have stated, it is the combination of the tests, however, that is important. The average standards are given in the following table:—

| | Average standard. | Minimum standard. |
|-----------------------------|-------------------|-------------------|
| Breath holding | 69 sec. | 45 sec. |
| Vital capacity | 3900 c. cm. | 3400 c. cm. |
| Expiratory force | 110 mm. Hg. | 80 mm. Hg. |
| Fatigue test (U tube) | 52 sec. | 40 sec. |
| Pulse response to exercise— | | |
| Increase per min. | 12-24 beats | 36 beats |
| Return to normal | 10-20 sec. | 30 sec. |

Practical Value of the Tests.

I believe that every pilot could be overhauled by the breath-holding, expiratory force, and U tube tests and a station graded according to its efficiency. As a matter of fact, this has been done. At a certain fighting station the medical officer found that the average for all the pilots by these tests were—

| | |
|---------------------------|-------------|
| Breath-holding | 65 sec. |
| Expiratory force | 103 mm. Hg. |
| Sustaining 40 mm. mercury | 67 sec. |

He picked out one officer as being badly off colour, a pilot with 250 hours' experience. The pilot soon after went for a flight, there was nothing wrong with the machine, but the pilot lost control, crashed, and was killed. His results for the three tests just previously were—

| | |
|-----------------------|------------|
| Breath-holding | 33 sec. |
| Expiratory force | 95 mm. Hg. |
| Sustaining 40 mm. Hg. | 22 sec. |

The medical officer had suggested that this officer should not be allowed to fly. This unfortunate incident so impressed the commanding officer that the medical officer was asked every week to grade the pilots. It soon became evident that the officers who were picked out by the commanding officer or senior flight officer for special duty were practically always those graded by the tests as extra fit. It would seem from this that the selection of pilots for special work by these tests if adopted would be of great value. The commanding officer eventually made a rule that if an officer did not come up to the standard of the tests he must not be placed in charge of a machine. The medical officer then gave him instructions for making himself fit, and he was told if he was still unfit by the tests in a fortnight he would go up for a board, and possibly be found unfit for flying. This was actually done in one or two cases. By this means the efficiency of the station was greatly increased.

I suggest that these tests would also be of value for measuring trench fatigue, industrial fatigue, and fatigue in women workers; also for the grading of people for positions of trust, such as special motor drivers and members of mine-rescue teams. With special standards set according to age, they would possibly also be of value to educational authorities in assessing how children are maintaining their physical efficiency.

THE TREATMENT OF VENEREAL DISEASE.

By SIR ARCHDALL REID, M.B. EDIN.;

AND

P. HAMILTON BOYDEN, M.D. EDIN.,

SURGEON COMMANDER, R.N.

EVERY great war has been followed by an increase in venereal disease, so marked that on occasions it has amounted to a pestilence. Unless timely sanitary precautions are taken the greatest of all wars is unlikely to furnish an exception to the rule. We think it desirable, therefore, to give an account of an essay in preventive medicine which, as may be judged from the following, achieved considerable success.

One of us (A. R.) has been in medical charge of a rapidly changing body of men generally numbering about 2000. Up to the end of 1916 venereal disease was common among them in spite of numerous moral lectures and in spite of adequate provision of what is known as "early treatment"—that is, disinfection after the "contact" has returned to quarters. At the beginning of 1917 a new system was instituted. The men were instructed to disinfect themselves immediately after danger had been incurred—just as a surgeon would disinfect his hands. This procedure is what is known as prophylaxis. It differs from early treatment merely in that the man carries the disinfectant and uses it immediately. Each man who applied was given an ounce of solution of potassium permanganate (at first in a strength of 1 in 2000, later in a strength of 1 in 1000), a small swab of cotton-wool, and careful directions. Potassium permanganate was chosen merely because it happened to be the most accessible disinfectant. The rationale of the procedure was fully explained, so that on an emergency the man could purchase the materials from any chemist. During 1917 and 1918 about 20,000 men passed through the station, and among them precisely seven cases of venereal disease occurred, six of gonorrhoea and one of syphilis. Of the six cases of gonorrhoea, two only were contracted by men on leave, in each case from the man's own wife. Two of the others were drunk and took no precautions. The fifth man was infected the night he arrived, and he also, being unaware of the system, took no precautions. The sixth man practised early treatment an hour after intercourse. The man who acquired syphilis also carried no disinfectant, and used it (permanganate and calomel) two hours after intercourse. He had a long prepuce, and therefore a sensitive gland, and probably did not—probably could not—rub in the calomel vigorously.

The other of us (P. H. B.) commenced prophylaxis against venereal disease in the Royal Navy in 1907. Some 18 months ago he took over medical charge of an establishment numbering

over 2000 officers and men. The amount of venereal disease, and especially gonorrhoea, was considerable, and it was recognised that of the men who stated they had used the so-called "dread-noughts" some 40 per cent. contracted the disease. It thus became evident that nargol jelly as a preventive was practically inert. For the past nine months the method of immediate prophylaxis by means of the application of a solution of potassium permanganate (1 in 1000) has been employed with results as striking as those mentioned above in the case of the soldiers. Not a single case of gonorrhoea occurred amongst those employing this method, and only one of syphilis. This latter made the application about six hours after exposure to infection, and may therefore be counted out. Unfortunately, the Navy is a very conservative body, and many men still persist in sticking to the "dread-noughts." But in lectures given on the subject of prophylaxis men are gradually being convinced of the simplicity and efficacy of immediate prophylaxis.

The calomel cream is still reserved for those who have omitted to carry the permanganate solution on their persons, as it seems likely that the former affords some protection, even if an hour or two has elapsed since the risk of infection has been run.

It will be seen that no man who followed instructions and disinfected himself immediately acquired disease. Evidently the time element is of extreme importance. Probably there is no special virtue in potassium permanganate. Any other active antiseptic would be equally effective. But permanganate is the cheapest disinfectant and the best known to the public, the least poisonous, and least irritating.

HILUS TUBERCULOSIS IN THE ADULT.

BY OLIVE RIVIERE, M.D. LOND., F.R.C.P. LOND.,

PHYSICIAN TO CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, AND TO EAST LONDON HOSPITAL FOR CHILDREN.

THE following case, one of many possible examples, illustrates a condition which must be very familiar to all with a wide or prolonged experience of chest disease.

Patient, aged 24 years. History of six months' cough and wasting, night sweats, dyspnoea on exertion, and poor appetite. The patient is very thin and sailow; there is no clubbing. Pulse 128. Temperature 102° F.

Chest.—Reflex bands of impairment are present over the backs. (See Fig. 1.) Movement is equal on the two sides. Percussion finds no impairment, but there is double paravertebral dullness, and the apical resonance (Krönig's isthmus) is narrowed to 2 cm. on both sides (normal 4½–5 cm.). There are no crepitations nor râles, the breath sounds are normal, and the air entry fairly good.

A radiogram shows "disseminated tubercle of fluffy character (alveolar)," to quote the radiologist's report, through both lungs. On the left side almost the whole field is filled, and there is cavitation just outside the root; on the right disease involves, in the main, the upper half of the lung. The root shadows are very heavy, and suggest glandular involvement.

Six weeks later the signs are similar, but a few crepitations have appeared at the left base behind.

Here we have a "central lung" or "hilus" tuberculosis of broncho-pneumonic type, the counterpart in the adult of a condition which is quite familiar to the paediatrist. Because, on account of its striking symptoms and fatal issue, such a case cannot well be overlooked nor the presence of disease denied, it serves very well to illustrate at the outset the condition which forms the subject of the present paper. If the existence of hilus tuberculosis in the adult had to be proved entirely on grounds of the far more common chronic cases, it might be more difficult to bring convincing evidence of its undoubted occurrence. When, however, a patient obviously "consumptive," presents a chest wall entirely innocent of those crepitations which are considered by many the main sign of tubercle, and yet a radiogram shows advanced and active disease, it seems difficult to deny that we are dealing with a process which has developed in the deep parts of the lung and has not yet involved the surface. If, in addition, before death, crepitations appear rapidly over one or both lungs, as commonly happens, then the evidence for outward-spreading disease is still more convincing.

Now, just as acute apical phthisis is rare, so also is acute hilus tuberculosis compared with the quiet and chronic forms which constitute, to those whose eyes are open to their existence, the main bulk of our tuberculous material. It is particularly to this latter class of case that the writer is anxious to draw attention in the present communication.

But before going any further it must be made clear that the term hilus tuberculosis of adults is not here used to include those evidences of obsolete tubercle which are to be found in every X ray plate and are apt to bulk large in the radiological report on a suspicious chest. Such scars of old battle are accompanied by no symptoms, and give rise to no clinical signs at the surface. True, at the time of their development in childhood physical signs were probably discoverable in some proportion at least of the more marked cases if looked for, but such signs vanished with the passage of years, and it is only when disease is reawakened and a fresh spread occurs that the chest changes to be presently described appear, and the case merits the designation of "hilus tuberculosis in the adult." This awakening of obsolete disease appears to add very little that is distinctive to the radiogram so long as disease is of a quiet and chronic type, and thus it happens that the clinician is in reality better equipped for the diagnosis of hilus tuberculosis of this type than is the radiologist. The former can point to signs indicative of recent disease as confirmation of the symptomatic evidence, the latter must rely solely on the symptoms, unfortunately seldom distinctive, as proof of present activity. This is, however, to anticipate what may be more appropriately discussed later on.

It must be understood, then, that the term hilus tuberculosis in the adult refers to a fresh and active process, involving the deep areas of the lungs where remain the old foci of childhood infection, and thence spreading outwards towards the surface. It thus stands in close relationship to the common form of tuberculosis of childhood, though with less tendency to glandular involvement; and also in decided contrast to apical phthisis of adults, a localised infiltration involving the apex of the lung.

Hilus tuberculosis is commonly a peribronchial disease of chronic and intermittent course—our first knowledge of it we owe to the radiologist, whose "peribronchial phthisis" and "peribronchitis tuberculosa" have referred, as a rule, to this condition. From the clinician it has suffered a scandalous neglect, and it is in the form of a somewhat belated atonement that the writer offers the present communication. Only two contributions to the subject on the clinical side have, up to now, come under the writer's notice, both somewhat inadequate from the point of view of the recognition and diagnosis of the disease. Philippi, of Davos, in 1911, gave an interesting description of "intrathoracic glandular and lung-hilus tuberculosis of adults" (to paraphrase his German heading), and in all but the means for its diagnosis the account is clear sighted and fairly complete. Straub and Otten, in 1912 issued from v. Romberg's laboratory in Tübingen a paper which showed that they recognised the hilus origin of certain clinically "unilateral" cases of advanced pulmonary tuberculosis; they do not deal with the early stages of the disease nor with its diagnosis, and many of their cases occurred in children rather than in adults.

Clinical Characteristics of Hilus Tuberculosis.

Before going into the symptoms and physical signs of hilus tuberculosis in the adult, or its differential diagnosis, it will be well to lay down in the rough the main characteristic points which distinguish it from apical phthisis.

1. *Its bilateral nature*.—Wherever the signs may appear on the surface in these cases the central lung disease is practically always bilateral, though stress may fall for a time more heavily on one or other lung. Its bilateral character is generally very evident to radiological examination; it reveals itself clinically in two directions: firstly, movement of the two sides is very commonly equal or nearly so; and, secondly, there is marked retraction of both apices (Krönig's area) to topographical percussion. (See Figs. 3 and 4.) In both these particulars it stands in marked contrast to apical phthisis, and the latter point, the double apical retraction, provides the means by which it is distinguishable from phthisis on the one hand, and from the chest of health, or of chronic bronchitis, on the other, these being the three conditions under which error most commonly arises.

And now if we look back to the case cited at the opening of this paper, what were the characteristic points to observe? (1) The equality of the two sides in movement and in "contrast percussion." (2) The double narrowing of the apices—only 2 cm. instead of the normal 4½–5 cm. Both these points are evidence of bilateral disease. (3) The absence of crepitations at the surface, evidence of the deep-lying location of the disease. And this last point brings us

to the second main characteristic of hilus tuberculosis—namely, the atypical distribution of the signs when they do reach the surface, a point in the diagnosis of cases already advanced.

2. *The atypical location of surface signs.*—Just as in pulmonary tuberculosis of the young child—always a hilus tuberculosis save where a miliary dissemination has occurred—the stethoscopic signs may appear at any point on the chest wall, and no spot is truly characteristic, so in hilus tuberculosis of the adult. When the disease which has been smouldering for so long, too often unheeded, deep in the lung, at long last reaches the surface, it does so at some spot other than the apex of the lung. Very commonly crepitations appear over the front of the chest on one side, often in the axilla, not infrequently at the base behind. Since disease spreads out from the root fanwise along the lung framework towards all points of the surface, it is obvious that it may first reach the stethoscope of the physician at any point. Similarly it must be expected that when disease has reached the surface at one point it will not be far from the surface at other points also. And this brings us to the third characteristic point about hilus tuberculosis.

3. *The characteristic spread of stethoscopic signs over the lung surface.*—Having once reached the surface at one point, the signs, crepitations and the like, tend quickly to spread, unless disease becomes arrested, over the greater part of that side, front and back, often within a comparatively few weeks. On this account it is not uncommon to meet with cases of clinically “unilateral” tuberculosis involving the whole or greater part of one lung and apparently sparing the lung on the opposite side. This unilaterality is, however, apparent only, and a radiogram will reveal disease of little less extent, though often of lower activity, throughout the other lung also. If disease is progressive in this second lung, and it soon becomes so when “tolerance” to autotuberculin fails and fever shows itself, signs will soon appear at this surface also and spread rapidly in area just as on the first side involved. Even before crepitations appear the patient may be dyspnoic and cyanosed from the abundance of deep disease.

Here, then, before discussing its physical signs and diagnosis, we have an outline of the three main characteristics which tend to mark down the hilus origin of a case of pulmonary tuberculosis. No further notice will be taken of cases so far advanced as to give stethoscopic signs at the surface, and, indeed, the majority of cases never reach this stage. The rest of our space will be directed to the symptoms, clinical signs, and differential diagnosis of hilus tuberculosis in its early and curable stages and in its chronic forms.

Symptoms.

Such symptoms as are of toxic origin are identical for hilus tuberculosis and apical phthisis. In addition, certain symptoms occur which may be considered more characteristic of hilus tuberculosis than of apical phthisis. Particularly, shortness of breath on exertion is a symptom which is often prominent, and due in some cases to widespread peribronchial disease and in some to the emphysema and bronchitis which are occasional complications. Chest pain is also fairly common, often in the central regions of the chest, occasionally in the side in association with the marginal pleuritis which are such frequent accompaniments of this disease.

Physical Signs.

A patient comes to his physician with symptoms suggestive of tuberculous chest disease, but on examination no signs are present pointing to the unilateral apical infiltration characteristic of apical phthisis—how is “central lung” or “hilus” tuberculosis to be detected? If this disease is present we shall find the following signs:—

Inspection and Palpation.

On inspection and palpation it will be established that chest movement is equal in the two sides, at least in early stages. In certain cases, however, the stress of disease may fall more decidedly on one lung, particularly the right, or decided pleuritic involvement may occur. Then of necessity a unilateral limitation of expansion is present, as in phthisis, and the characteristic balance of movement is lost.

Percussion.

Through percussion are achieved the main elements of diagnosis.

1. *The reflex bands of impairment* over the backs described by the writer in a former communication¹ as evidence of active parenchymatous disease will be present (see Fig. 1).

2. There may be a slight difference of note between the two sides of the chest to “contrast percussion”; and this is commonly against the right side.

3. Often there is present a wide and well-marked area of *paravertebral dullness* on the right side (Fig. 2), a point on which Philipp² very rightly laid stress in the diagnosis of these cases. This area is familiar to pediatricists and is acknowledged evidence of intrathoracic glandular enlargement, mainly, the writer has reason to believe, enlargement of bifurcation glands causing pressure on the right pulmonary artery, and thereby reducing the function and volume of the right lung. This dull area may overstep the normal “oval interspinous dullness” (see Fig. 2) between the first and fifth dorsal spines, so as to stretch out some 6 or 7 cm. on one or both sides and extend down to the sixth or seventh dorsal spine.

Parasternal dullness is sometimes present, though less often than paravertebral, and it generally points to enlargement of lateral tracheal and tracheo-bronchial glands. Normally there exists some 2½ cm. (1 inch) of impairment on each side of the sternal border, and this may be increased in these cases to 5 or 6 cm. on one or both sides.

Fig. 1.—Reflex bands of impairment. Fig. 2.—Paravertebral dullness. Figs. 3 and 4.—“Krönig's isthmus” of apical resonance, normal and reduced.

4. Most important of all as evidence of deep disease we find a *bilateral narrowing* of “Krönig's isthmus” of apical resonance at the top of the shoulder. (See Figs. 3 and 4.) In the normal chest this “isthmus” measures 4½ to 5 cm. on each side, though in women and undersized men of sedentary occupation it may fall as low as 4 cm. In cases of hilus tuberculosis we find it considerably reduced on both sides, very commonly to 2½ cm. This bilateral narrowing gives us valuable evidence in two directions. Firstly, it is no healthy chest we are examining—though nothing else can be found at the surface we can be quite sure that some central disease, whether of present or recent activity, is present. Secondly, a bilateral narrowing is not characteristic of apical phthisis, save in its later and bilateral stages when abundant other surface signs will be present. In phthisis, as a rule, the retraction of the isthmus is less marked—often only to 3½ cm.—and in early stages is unilateral.

A comparison of the width of the apical resonance in a number of cases taken at random will serve to bring out clearly the importance of this sign in the differential diagnosis of hilus tuberculosis.

| Hilus tuberculosis. | | Apical phthisis. | | Chronic bronchitis. | |
|---------------------|--------|------------------|-------|---------------------|--------|
| Right. | Left. | Right. | Left. | Right. | Left. |
| 2½ cm. | 2½ cm. | 3½ cm. | 6 cm. | 4½ cm. | 4½ cm. |
| 2½ " | 2½ " | 2½ " | 5½ " | 4½ " | 4½ " |
| 3 " | 3½ " | 5 " | 3 " | 5½ " | 5½ " |
| 2 " | 2 " | 3½ " | 4 " | 3½ " | 3½ " |
| 2½ " | 2 " | 6 " | 3 " | 4 " | 4 " |

5. In hilus tuberculosis of adults *tidal movement* at one or both bases may be diminished or may entirely fail. In the absence of extensive lung disease loss of tidal movement usually indicates adherent pleura, and this is especially so where the loss is on one surface only. Pleurisy is a very frequent complication of hilus tuberculosis, but pleural adhesions are by no means a necessary accompaniment.

¹ THE LANCET, 1915, II., 387.

Auscultation.

Of auscultation in all but the last stages of hilus tuberculosis there is little or nothing to be said. As already indicated, the surface will be entirely free of stethoscopic signs, even though extensive disease occupies the deeper parts of the lung. Still more is this the case in those earlier or more chronic cases for whose recognition and detection the writer here offers a plea.

But though no crepitations are to be expected at the surface in such cases, other signs may be incidentally met with in certain cases. Thus, fleeting marginal pleurisies are common, and fine friction, with or without pain, may be discovered at one or other base or axillary region. Fine inspiratory sounds of indeterminate or mixed nature are also often heard at the bases in cases of hilus tuberculosis in the adult, as in children. These may be atelectatic, or may stand for cedema or lymph stasis, or may be mere tissue sounds developed under pressure of the stethoscope—their nature generally remains undecided! If the breath sounds are "blowing" at the right apex, as sometimes happens, this may be due to glandular enlargement, and is not necessarily evidence of pulmonary consolidation.

Radiographic Appearances.

Something must be said of the radiographic appearances, and these may be conveniently divided into three types according to the activity of the process.

Chronic and quiet disease with little or no evidence of activity.—This represents perhaps the commonest type of case, the evidences of activity being entirely dependent on other factors than the X ray picture. The main point about the radiogram is the abnormal visibility of the whole lung reticulum, which appears thick and strongly shadowed in all its "twigs" right out to the periphery. The main branches appear thickened, often wide and tape-like, or may appear as rings or figures-of-eight, with or without some dilatation of their lumen. The whole picture has a general "fibrous appearance," nodules may be absent and yet the case tuberculous, or there may be a nodular appearance throughout. In many of these chronic cases the radiogram may present so "fibrous" a picture that it is hard to believe any activity can be present. Yet the patient may present symptoms and develop a fresh pleurisy as evidence that the process is not obsolete.

In hilus tuberculosis, of whatever form, it often appears that the diseased area is, roughly, equal on the two sides and often reaches nearly to the periphery; it may present a sharply-marked outer margin, giving a butterfly appearance and strongly suggesting a simultaneous spread out to this point rather than a slow creeping outwards. Indeed, judging from the X ray and post-mortem experience, the writer is convinced that a simultaneous "sowing" of disease over a wide area occurs not infrequently, though the gradual outward spread presumed in the general description of the disease can also be proved to occur, and is perhaps the rule.

More active disease.—This may show itself in a more woolly and less sharp-cut appearance of disease which yet remains, to X ray examination, purely "peribronchial." The thickening of the bronchi is more marked both round the root and farther out in the lung, and a nodular or even "budding" appearance may be noticeable. The finer network of the lung is thickened irregularly or nodular shadows of various size and not very sharp outline may be linked up in it.

Active and acute disease.—This is sufficiently illustrated by the X ray plate of the case described at the opening of this paper. The strands of the lung network vanish and the pulmonary fields become filled with woolly bronchopneumonic shadows of smaller or larger size, with eventual coalescence and cavity formation.

Differential Diagnosis.

And now, having indicated something of the symptoms and physical signs, and of the general characteristics of hilus tuberculosis in the adult, it still remains to emphasise the main points in its differential diagnosis. And first of all it is necessary, in the early cases, to indicate the points which separate the *healthy chest* from that containing a central lung lesion. For those who are careless over their physical signs the healthy chest is merely one that presents equal movement on the two sides, no obvious areas of dullness, and no stethoscopic signs. But the chest of early hilus tuberculosis shares with the normal chest all these negative points; hence these are useless in its diagnosis. Only after Krönig's isthmus has been carefully mapped and measured, paravertebral and parasternal dullness searched for, and, less important, tidal movement at the bases explored, can early hilus tuberculosis be excluded. In particular, it cannot be too strongly insisted that Krönig's apical resonance represents one of the essentials of chest

examination, since it supplies practically the only key to the condition of the central area of the lung. True, the X rays will also reveal these central areas, but the information they give is largely clouded by the constant presence of the shadows of obsolete tubercle remaining from the common childhood infection; the question of recency and activity cannot be decided with the X rays save for acute forms of the disease, with which we are not here concerned. The points on which a differential diagnosis must be based may be shortly indicated as follows:—

| — | Normal chest. | Early hilus tuberculosis. |
|-----------------------------------|-------------------|---|
| Reflex bands (Fig. 1). | Absent. | Present. |
| Krönig's isthmus (Figs. 3 and 4). | Of normal size. | Contracted on both sides. |
| Paravertebral dullness (Fig. 2). | Absent. | Often present on right side. |
| Parasternal dullness. | " | Present in some cases. |
| Tidal movement. | Of normal amount. | Often absent or reduced on one or both sides. |

Having discovered through the evidences of these signs that the chest under consideration is outside the normal, what proof have we that the malady is of tuberculous causation? Often, it must be confessed, very little in the individual case. For hilus tuberculosis may smoulder for years without any very characteristic symptoms, and tubercle bacilli may be absent from the sputum almost throughout its course. Where there are definite evidences of glandular enlargement, as shown in paravertebral and parasternal dullness, the case presents striking similarity to tuberculosis of childhood, and there exists strong probability of its tuberculous nature. Where, however, the only definite sign is a double narrowing of Krönig's area (and again it must be insisted that a healed childhood infection does not leave this sign behind), we have evidence of a central lung lesion but none of its activity, and still less of its tuberculous causation. We must look elsewhere—to symptoms mainly—for evidence that disease is not arrested or healed, and in doing so we sometimes find tubercle bacilli present and our whole difficulty solved.

Failing this fortunate chance, only an appeal to experience can supply us with means of reaching conclusions at least of high probability. For, apart from the well-recognised predilection of tubercle for the lung root, its almost constant presence as the result of a childhood infection, and its known tendency in this situation to persistent quiet activity and intermittent spread, we shall have clear recollection of patients with identical physical signs who later passed over into the region of proved tuberculosis. (The writer is here presuming that his own experiences are, or may become, common to others.) Our position is little worse than in the diagnosis of apical phthisis in the absence of bacillary sputum, again a matter of probability of a high degree.

"Given apical changes," remarked Turban, "without previous pneumonia, and when inhalation of dust can be excluded, then the diagnosis is almost certain."

And the same might be claimed, perhaps, for central or hilus lung disease. A patient with narrowed apices and suggestive symptoms, but with no history pointing to dust inhalation, may be regarded as probably suffering with active peribronchial tuberculosis; a patient with narrowed apices and no symptoms is probably the victim of arrested disease of similar causation. For, failing this explanation, there must exist a disease, presumably a peribronchitis of chronic course, of whose causation and pathology we are at present entirely unenlightened—a rather improbable proposition in the writer's opinion. Only occasionally, indeed, in these cases do other points fail to give additional support to their presumed tubercular origin—paravertebral dullness in a large proportion of the cases, and not infrequently the occurrence of a "marginal" pleurisy at one or other base.

The differentiation of hilus tuberculosis from *apical phthisis* is, as a rule, simple and straightforward, particularly in its early stages. With the advance of disease the two conditions may become difficult or even impossible to separate. Indeed, it must be admitted that between the two characteristic types intermediate pictures of disease may be observed not clearly conforming to either, or possibly a blending of both. But in spite of this occasional failure of type the differential diagnosis can generally be made, and

It is always worth an attempt on account of the differing course and prognosis in the two conditions. For hilus tuberculosis is nearly always of peribronchial type and extreme chronicity; tending to spread over wide areas, often with greater mechanical than constitutional disturbance; becoming arrested for long periods; showing occasional activity, often of a pleuritic nature, and then again dying down. Smouldering always, and always difficult to quench, but only at long last, and in exceptional cases, breaking into a conflagration of such intensity as to threaten life, and then usually at so advanced a stage that the outlook is obviously hopeless. The broncho-pneumonic case quoted at the beginning of this paper presents only a rare exception to the usual course.

In all particulars of its spread it stands in some contrast to apical phthisis, of which the immediate prognosis is always more serious and uncertain, and which moves forward more rapidly, accompanied by fever and constitutional disturbance, albeit with periods of arrest, towards its ultimate ending in death or cure.

Already, under the heading of the characteristics of hilus tuberculosis, some of the main points of distinction from apical phthisis have been insisted on—its bilateral character from the beginning, its appearance at other points than the apex of the lung, and its spread over a wide area of the chest wall once the surface is reached. In practice the differential points may shortly be tabulated as follows.

| | Hilus tuberculosis. | Phthisis. |
|---------------|--|--|
| Inspection. | Nothing characteristic, but any change, such as flat chest or emphysema, will be bilateral. | Flattening or hollowing and lagging of one apex in advanced disease. |
| Per-cussion. | Perhaps slight "contrast" impairment on one side, generally the right. Parasternal or paravertebral impairment, or both. Bilateral narrowing of Krönig's isthmus. (Fig. 4.) | Decided impairment at one apex. Neither. |
| Palpation. | Movement equal or nearly so on the two sides. | Unilateral narrowing of less extent. Unilateral deficiencies of movement. |
| Auscultation. | No stethoscopic signs at earlier stages, at most fleeting pleuristics or transient basal crepitations; then granular breath sounds over a wide area, changing to crepitations. Wide areas involved, often the middle or base of the lung. Often the whole of one lung involved before signs appear on opposite side. | Fairly early stethoscopic signs at one apex, soon crepitations here, later at opposite apex. |

So much for the differential diagnosis between these two forms of pulmonary tuberculosis, or rather between fairly typical cases of each. That many borderland cases occur whose classification is doubtful the writer has already indicated, but the classical case of hilus tuberculosis at a characteristic stage clearly belongs to a type by itself. Where an element of doubt in their differentiation must sometimes exist is in the eventual progress of certain early examples of disease—whether these must necessarily be regarded as on the way to become hilus tuberculosis as we eventually see it, or whether their future advance might be on the lines of an apical phthisis. This is a matter on which there can exist no great certainty at present. For these earliest examples might possibly represent, in some cases at least, a "sub-tuberculous" stage from which both phthisis and hilus tuberculosis may later emerge, and the writer has not shut his eyes to this possibility. But for one of these early cases, with double narrowing of apices, to progress towards apical phthisis it would be necessary for this apical contraction to open out. This the writer has never known to occur under observation, unless perhaps partially in a single case. As a rule, the apices tend to become narrower with time, whether with a spread of disease in a progressive case, or with fibrotic changes where repair is taking place. More tempting is it to assume a true etiological distinction between the two types of disease, hilus tuberculosis being regarded, as the writer has frankly presumed it at an earlier stage of this paper, as a reawakening of the arrested lesions of childhood, and phthisis as a reinfection from without. If this were a true picture of the case, then there could of necessity be no early stage common to both diseases.

Variations in Type of Case.

And now, at the close of this paper, it is necessary to mention the existence of certain variations from the common type of hilus tuberculosis outlined above.

1. *Hilus tuberculosis associated with bronchitis.*—In many cases of hilus tuberculosis of chronic "peribronchial" type there is a tendency to attacks of bronchial catarrh, and the recurring cough and sputum are often, in all probability, of this origin. Certain cases may, indeed, present all the symptoms and many of the signs of chronic bronchitis with emphysema, and often with asthmatic attacks.

As a rule, there are certain points which direct attention in such cases to the underlying tuberculous disease. The history is likely to be of short duration, and wasting will generally be a prominent symptom. Often one or more brothers and sisters of the patient are pronouncedly tuberculous. The pulmonary signs may be in most respects typical of chronic bronchitis, though often with a bias of signs against one side of the chest. But it is to a narrowing of Krönig's isthmus that we must look for more definite evidence of central disease. In chronic bronchitis it might well be expected that Krönig's isthmus would commonly, owing to the presence of emphysema, show a more or less striking enlargement. In some cases, truly, the apex may be as wide as 5½ cm. or even 6 cm., or it may maintain the normal 5 cm.; but much more frequently the raising of the shoulder girdle, and possibly also the development of some amount of peribronchial fibrosis, tend to reduce the isthmus to a figure rather below the normal, often to 4½ cm. or 4 cm. In some cases where the isthmus is diminished to 3½ cm. doubt will be felt whether the condition belongs to the category of simple bronchitis or not. Where the reduction is to 3 cm. or 2½ cm. there is decided evidence of central lung disease, and in the absence of a history of exposure to dust diseases this will probably be hilus tuberculosis. The possibility of tubercle masking under the guise of asthma or chronic bronchitis must always be borne in mind.

2. *Hilus tuberculosis, with tuberculosis of manifest glands.*—These are cases in which gross enlargement of the cervical and axillary glands occurs, and sometimes of other groups. The lung condition is usually a secondary incident, and the chest picture is that of enlarged chest glands. The writer has had five such cases under his care, and in two of these there was associated enlargement of the thyroid gland. It is to this class of case that Philippi called particular attention, insisting above all on the characteristic parasternal and paravertebral dullness.

3. *Hilus tuberculosis of broncho-pneumonic type.*—This has already received illustration at the outset of this paper. Suffice it to remark once again that this represents but a rare variety of the disease. Hilus tuberculosis in its characteristic type runs a chronic and intermittent course, and when the proper means are employed for its recognition it will be found to be of widespread distribution, and even to constitute the most prevalent form of pulmonary tuberculosis in the adult as well as in the child.

Queen Anne-street, W.

THE SUBSTITUTION OF AIR FOR OXYGEN IN ANÆSTHESIA WITH HEWITT'S GAS AND OXYGEN APPARATUS.

BY J. H. FRYER, M.B., B.C. CAMB.,
CAPTAIN, R.A.M.C. (T.C.), 53RD GENERAL HOSPITAL, B.E.F.

SOME months ago, during a temporary failure in the supply of oxygen for anæsthetic purposes, it occurred to me to try ordinary air in place of oxygen with the Hewitt's apparatus in general use here. This proved so satisfactory that the use of gas and oxygen has been entirely discontinued at this hospital, and some hundreds of administrations of duration varying from a few minutes to a full hour have been given by the air method.

The air is supplied by a foot-bellows such as that made by Messrs. Fletcher, Russell and Co., of Warrington, which is attached to the oxygen tube of the apparatus, and the two bags are easily kept full by the same foot.

The Hewitt apparatus is provided with a series of ten holes for the graduated introduction of oxygen to the inhaler, and by means of a coarse adjustment representing 10 and 20 holes the number used can be varied from 1 to 30. In working with air it is, of course, necessary to use a freer entry than is the case with oxygen. The method employed is as follows:—

A perforated metal "cotton-reel" gag is placed between the teeth, and a square of Gamgee tissue with a central cruciform hole intervenes between the face and the mask. The gag is set slowly leaking from the cylinder into its bag, so as to keep it just fully distended, while the air-bag is kept in the same condition by the foot-bellows. About seven "holes" are opened for air entry at the beginning of the administration, and this number is rapidly increased by means of the coarse adjustment to nearly the full 30 as soon as the breathing becomes deep. This is in some cases

sufficient to avoid all cyanosis, stertor, or jactitation, during the induction period, but many patients also require an occasional breath of pure air at this stage. The pupil dilates somewhat towards the end of the induction period, but soon returns to a mid position and remains so throughout the administration. The colour is, on the average, slightly more dusky than when oxygen is used, but the difference is small. The induction takes distinctly longer than with oxygen, and the surgeon generally wishes to begin too soon.

Breathing soon becomes regular and moderately deep, and the air entry can then be reduced. There is much variation between different individuals in the amount of air required to maintain complete quiet anaesthesia. The average amount is 15 to 20 "holes." Some do best with fewer than ten, while others require nearly the full 30 "holes," and others, again, an occasional breath of pure air in addition. Towards the end of a long administration more air and less gas is needed, especially with greatly debilitated subjects.

No ill-effects have been noticed during or after administration, and I have not come across any instance of post-anaesthetic vomiting. The limitations of this method are much the same as those of gas and oxygen, though it is undoubtedly easier to produce and maintain a satisfactory degree of muscular relaxation when using air. It is very easy to administer in cases where vitality has been reduced by shock, hæmorrhage, or sepsis, while strong, full-blooded men are difficult subjects.

I have not so far used the method for intra-abdominal operations, and for intra-thoracic I prefer oxygen bubbled through chloroform and warmed by the Shipway apparatus; but for amputations and most general surgical procedures it is well adapted unless postural requirements contra-indicate by rendering it difficult to maintain the face-piece in position. This method has advantages over gas and oxygen from the points of view of economy and portability of apparatus.

STAMMERING IN THE WAR PSYCHO-NEUROSES.

By E. PRIDEAUX, M.R.C.S., L.R.C.P. LOND.,
TEMP. CAPTAIN, R.A.M.C., EWELL WAR HOSPITAL.

STAMMERING is a common symptom of the war psycho-neuroses, and appears to be one of the most difficult symptoms to treat. The original theories on stammering pointed to some physical cause as the basis of the condition and regarded as responsible factors some weakness of the organs of articulation, or tongue, or incorrect respiration with spasms of the diaphragm, &c., perhaps connected in some way with the blood-supply of the brain. Most of the treatment at the present day has been based on these old theories and consists of various forms of complicated speech-drill and regular breathing exercises. The partially successful results, obtained by these methods, have convinced both the instructors themselves, and others, of the apparent truth of these theories, and there seems some danger that we should lose sight of the real nature of the affection and the process underlying the mechanism of its cure.

The Part Played by Suggestion.

The history of the treatment of stammering, which includes the use of drugs, both internally and externally, surgical operations such as that of Dieffenbach by cutting the root of the tongue, or of Braid, by removing the tonsils and uvula, various forms of electricity and hypnosis, all of which have been successful in their day, must make one suspect that the present various methods of speech-drill and breathing exercises, owe their efficacy to the same mechanism—namely, "suggestion."

My own experience in the treatment of war stammerers has convinced me that this is the case. I have removed stammers by direct verbal suggestion, both in the waking and hypnotic states, and by indirect suggestion by insinuation, with the help of electricity, or different forms of exercises and speech-drill, the effects of which have produced physical reactions directly opposed to each other. I have also used Luys' old method of so-called "transfer," with the help of a hypnotised subject. Some of the patients treated by these methods had been attending stammering classes for five months, and gave up their stammer in as many minutes.

Just as a stammer can be made to disappear by suggestion so it can be reproduced by suggestion in certain subjects. A few of my cases give a history of beginning to stammer only when being brought into contact with other stammerers. This is the process named by Freud "identification." They stammer because they have had the same experience as the others, and do so by auto-suggestion. I have never known a patient who is undergoing treatment and understands his condition get a stammer in this way.

Stammering as a Symptom of Hysteria.

Stammering, then, must be considered as a symptom only of hysteria, for it even conforms to Babinski's limited definition¹ that "hysteria is a pathological state manifested by disorders, which it is possible to reproduce exactly by suggestion in certain subjects, and can be made to disappear by the influence of persuasion (counter-suggestion) alone."

It is also a very good example of Janet's² "disposition to equivalences" in hysteria, the tendency of one apparently quite different symptom taking the place of another. Yealland's³ case of an officer with monoplegia of the lower limb who returned two days after his leg had been cured, with a stammer, is an instance of this disposition. An interesting case of mine showed this very markedly. The patient had been a stammerer since childhood, and at the age of 21 developed a monoplegia of the right arm after an accident. Two months elapsed before he came to me for treatment, and during this time and on admission he had no trace of stammer. After recovering the use of his arm the stammer returned, and was removed by further mental analysis.

Stammering following removal of mutism and aphonia is also an example of the disposition to equivalences, and does not occur after modern psycho-therapeutic methods. In the same way other symptoms may appear as the result of removing a stammer, when the underlying psychical cause has not been discovered and explained to the patient.

The psychical nature of the condition is also shown by the following facts. In my experience stammerers who have developed their stammer after having once learnt to talk normally in childhood, do not stammer in their sleep, or when standing on their heads; they can sing and whisper without stammering, and stammer less, or not at all, when talking to inferiors, or reading aloud to themselves. On the other hand, they stammer more when in a state of emotion, and stammer particularly over words and incidences which are associated with some past emotional experience of a painful nature.

These facts have led me to believe that the physical theories as to the origin of stammering, such as hyperæmia of the brain,⁴ muscle spasms, and weakness of the organs of articulation, are quite untenable, and that the present treatment, by physical methods founded on these theories, is wrong in principle, and often does harm, even when it is used by those who recognise the psychical nature of the condition.

Treatment.

In the war psycho-neuroses we meet with two distinct classes of stammer:—

1. That in which the stammer is more or less constant, when the patient does not really concern himself about his stammer; it resembles in this respect mutism, aphonia, monoplegia, &c., and is the true hysterical type, belonging to Freud's "conversion hysteria" class.

2. That in which the patient is intensely anxious about his stammer, and in which the dread of stammering is sufficient to keep up the condition. It may only occur in a state of emotion, and it is more marked in relation to words and incidents associated with past emotional experiences. This is the "psychasthenic" type, and belongs to Freud's "anxiety hysteria" class.

The treatment of these two classes is fundamentally the same—viz., finding out the underlying psychical cause for the origin of the stammer, which will be found to be connected with some past emotional experience of a painful nature, giving rise to mental conflict and undergoing repression.

In the true hysterical type I think it is better to remove the stammer first by some form of persuasion or suggestion, using the simplest method possible, so that the patient realises that he himself is responsible for the cure, as emphasised recently by Dr. T. A. Ross.⁵ Physical exercises for this type may be used as a means of suggestion and do no harm,

provided that the process is carried through in one sitting, but they are not necessary. After this a short mental analysis and explanation are required to complete the cure. I used to rely on some form of suggestion only, but I soon found that permanent cure was uncertain. The analysis must discover the moment when the stammer or its equivalent symptom first appeared and the circumstances which led up to it; all the unpleasant experiences must be fully brought back to memory, so as to produce complete abreaction, and the patient must be encouraged to talk freely about them, for "an emotion, which is judged, and which has become an integral part of acquired consciousness, is by this very fact no longer an emotion."

The treatment of the psychasthenic stammer is more difficult, and more prolonged mental analysis is generally necessary. In this class I think that physical exercises definitely do harm. They attract the patient's attention still more to his speech, make him painfully conscious of his stammer, and increase his dread, thereby increasing the repression of his past experiences. I find that it is better to make no attempt to treat the psychasthenic stammer as such. I explain to the patient why he stammers, and reassure him as to its removal. I tell him that the stammer is only an expression of the condition of his mind, just as weeping is, but that in the former he is unconscious of the cause, and that when we have discovered the cause the stammer will disappear. When this has been done, and the patient is able to talk about his experiences without emotion the stammer gradually disappears.

My experience of war stammers has convinced me that stammering in civil life must be due to similar causes, that habit does not play such an important part as is supposed, and that the best method of treatment is by mental analysis.

A SIMPLE METHOD OF STAINING THE DIPHTHERIA BACILLUS BY A TOLUIDINE BLUE ACETIC ACID MIXTURE.

By P. L. SUTHERLAND, M.B., CH.B., D.S.C. GLASG.,
BACTERIOLOGIST, WEST RIDING COUNTY COUNCIL.

NUMEROUS methods of staining have been devised to differentiate the *Bacillus diphtheriae* from allied organisms occurring in cultures from throat swabs. Of these methods that of Neisser is probably the most extensively employed, as experience has shown it to be reliable, and it clearly brings out the characteristic polar bodies of the bacillus. Neisser's procedure has, however, the disadvantage that the counter-staining, washing, and drying of the films occupies a considerable amount of time, a matter which is of importance in public health laboratories where large numbers of cultures are examined daily. For routine examinations the use of methylene blue applied in the manner recommended by Cobbett and Phillips (1897) has the advantage in this respect. In this method the smear is made on a cover-glass and is allowed to dry; a drop of dilute Löffler's methylene blue (1 in 5) is then placed on a slide and over this the cover-glass is placed film side down. The excess of stain is removed by pressing the preparation cover-glass downwards on a layer of filter paper and the specimen is ready for examination. The staining is inferior to that obtained by Neisser's method, as the *Bacillus diphtheriae* has very frequently a segmented appearance and the polar bodies are not clearly shown, with the result that it is often difficult to distinguish it from the longer forms of Hofmann's bacillus. Later, Cobbett (1901) showed that by running a few drops of dilute acetic acid (5 per cent.) under the cover-glass the bodies of the bacilli become decolourised, and the polar granules tend to become more clearly defined.

After a considerable experience of the use of Cobbett's method it was thought that it might be possible to prepare a stain which, applied in a similar manner, would give results more closely resembling those obtained by Neisser's stain. Numerous stains and combinations of stains were tried, and it was found that toluidine blue, owing to its polychromatic properties, gave the most satisfactory results. The use of

toluidine blue for the staining of *Bacillus diphtheriae* has already been recommended by Pugh (1905) and by Ponder (1912). Pugh's formula was tried, but was found to contain too much acetic acid.

The stain, the composition of which is given below, was finally adopted in the Public Health Laboratory, Wakefield, in 1910, and the formula was published in a short note in the bacteriological section of the annual report of the county medical officer for the West Riding of Yorkshire for that year. The method has now been in use for a period of eight years, during which time the annual average number of specimens examined has been 7000; it may, therefore, be of interest to those engaged in similar work to describe the method.

The staining solution, which keeps well, has the following composition: toluidine blue, 0.1 g.; glacial acetic acid, 0.5 c.c.m.; distilled water, 100 c.c.m.

The smears are made on slides and are fixed with heat in the usual way. When large numbers of cultures have to be examined it is most convenient to make the smears in a series of 10 or 12 at one time. A drop of the stain is placed on each film and a cover-glass is then placed over the preparation. The excess of stain is removed by blotting each slide between two layers of blotting-paper immediately before being examined. The first slide is ready for examination about one minute after the stain is applied, and the others are taken in rotation. The best results are obtained by using strong artificial light.

When stained in this way the polar granules of the *Bacillus diphtheriae* are of a deep reddish-purple, while the bodies of the bacilli appear faintly blue. Most of the organisms found in diphtheria swabs, including Hofmann's bacillus, are more faintly stained, so that the *Bacillus diphtheriae* is readily detected when present only in small numbers.

The stain may also be used in a similar manner for demonstrating the bacillus in smears made direct from the swabs, in which case the film should be allowed to stand in the stain for from two to three minutes before removing the excess.

Corrigendum.—At the head of the last column of the table illustrating Dr. I. Harris's note on the Inverted "T" in the First Lead of the Cardiogram (THE LANCET, Feb. 1st, p. 168) ? T. should read ? P. T was inverted in all the cases. We regret the error, which was not the author's.

LITERARY INTELLIGENCE.—The University of London Press announce the issue of five further volumes in their Military Medical Manual Series as follows: Disabilities of the Locomotor Apparatus, by Aug. Broca, edited by Sir Robert Jones; Electro-Diagnosis of War, by A. Zimmermann and P. Perol, edited by Dr. E. P. Cumberbatch; Wounds of the Pleura and Lung, by R. Grégoire, edited by Lieutenant-Colonel C. H. Fagge; Mental Disorders of War, by Jean Lépine, edited by Dr. Charles Mercier; Commotions and Emotions of War, by A. Leri, edited by Sir John Collie.

A DOCTOR'S WELCOME IN UGANDA.—Medicine earns its due meed of recognition in Uganda, where, at Kampala, Dr. Albert Ruskin Cook, superintendent of the hospital, had a great reception from the European, native, and Indian communities on his recent return from England, where he had received a decoration of the Order of the British Empire. At the official residence of the Kabaka there was a large gathering of guests assembled to present an address of welcome, including the Bishop of Uganda, Mr. Pellew-Wright, the Deputy Commissioner, and Sir Apolo Kagwa, ex-Regent and present Prime Minister. The address was read by the Lukiko's secretary, Musa Musoke. The Indian community erected a handsome arch on the public road bearing the inscription, "Welcome to Dr. and Mrs. Cook." A necklace of flowers was presented by Mr. M. M. Khandwala, president of the Indian Association, who also read an address of welcome. The day ended with the cutting the brides' cakes by Dr. Cook and his wife for the double wedding in Namirembe Church, when the twin daughters of Sir Apolo Kagwa were married to the sons of important chiefs.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Gonorrhœa of the Genito-urinary Passages.

A MEETING of this society was held on Jan. 27th, Dr. A. F. VOELCKER (Major, R.A.M.C.T.), the President, being in the chair, when Brevet Colonel L. W. HARRISON opened a discussion on Gonorrhœa of the Genito-urinary Passages.

Colonel HARRISON said: I confess that since I accepted the honour of your invitation to open a discussion on gonorrhœa I have looked forward to the event with considerable misgiving. For I have no hope of being myself able to say anything which is new and instructive to the members of this learned society, and can only trust that I may induce others to discuss certain details connected with the treatment of acute gonorrhœa which may be interesting and profitable to us all. The points which I propose to raise are connected with the abortive treatment of gonorrhœa, some details of the technique of irrigation, and the attack on the gonococcus through the blood stream.

Abortive Treatment of Gonorrhœa.

In other places I have frequently said that if the general public only realised how easy it is to abort gonorrhœa when treatment commences on the very first day, and yet how very difficult it is to cure it when it has been given a start of even two days, they would apply for advice on the first appearance of any abnormality, and gonorrhœa would cease to be the scourge it is. As you know, the gonococcus is an extremely easy germ to kill with antiseptics, provided that those antiseptics can only reach it, and had it not been for its faculty of penetrating to the deeper layers of the mucosa and into the follicles and crypts opening on to the mucosa, the gonococcus would long ago have ceased to exist.

We can reckon with a fair amount of certainty on all the gonococci within an urethra being accessible to antiseptics *only on the first day of the disease*, so that promptitude of action is of the very first importance. Unfortunately, in the very great majority of cases the patient will go on hoping for the best until the discharge has become frankly purulent, and by that time the gonococcus is well out of reach. Our colleagues of the Overseas Medical Services have been pioneers in a widespread endeavour to break down this fatuous optimism of patients by diligent propaganda and have met with a considerable amount of success. I would quote in this connexion Lieutenant-Colonel Raffan, of the A.A.M.C., who has informed me that in a period of six months the 18 abortive treatment centres which the Australian authorities established in this country were successful in aborting over 2600 cases of gonorrhœa. He agrees with Ballenger in expecting 90 per cent. of successes when the treatment commences on the very first day, success meaning complete cure in a week or ten days.

Encouraged by the success of the Colonial medical authorities, I obtained consent in the latter end of last year to the establishment of an abortive treatment centre for Imperial troops in the London district. We have not met with such a high percentage of success as have the Australians, mainly, I think, because practically all the cases on which we have attempted the abortive treatment have been in the second or even third day of the disease. From August last to the end of 1918, out of 738 cases of gonorrhœa which reported at the centre, 129 were considered worth the attempt at abortion. In 69 the attempt failed, and the patients had to be admitted to hospital; in 10 cases the patient failed for one reason or another to complete the period of observation after completion of the treatment, so that it is uncertain whether the attempt was successful or not, and in 50 cases the disease was aborted in a week or ten days. I may mention that in all cases the diagnosis was verified by microscopical examination of the urethral secretion and the cure by examination of the patient a week after cessation of all treatment. As I mentioned, I think that our success would have been considerably greater if our cases could only have started treatment a day earlier, and I have seen sufficient of the abortive treatment of gonorrhœa to urge on you the importance of spreading a knowledge of its possibilities amongst the general public.

Technique.

We have tried many of the plans which have been recommended for the abortion of gonorrhœa, including iodoform bougies, large irrigations with permanganate of potassium, and Ballenger's sealed-in treatment, in which about 20 minims of 5 per cent. argyrol are sealed into the urethra for six hours. The Ballenger method proved fairly successful, but our cases were mostly too far advanced for its application, and our present method is as follows:—

1. The parts are thoroughly disinfected with 1/2000 perchloride of mercury solution.

2. The urethra is irrigated with 1/4000 permanganate of potassium solution, using a two-way nozzle and about two pints of solution.

3. Ten per cent. argyrol or 5 per cent. protosil solution is injected into the urethra and retained for 20 minutes.

This is repeated twice daily for 3-4 days and then the silver compound is omitted, the permanganate irrigation being continued for another 4-6 days. Films of the urethral secretion are examined every other day for gonococci to judge the prospects of success. When the discharge has completely ceased or has become extremely scanty and no gonococci can be found in it after an honest search, the treatment is omitted for a day, and if by the tenth day the urethra seems to be perfectly quiet all treatment is stopped and the patient told to report again in a week for confirmation of the cure. Sometimes he comes back in a few days with a return of the discharge and is then admitted to hospital as a failure. The after progress of patients who have been so admitted has been quite as good as, if not better than, that of patients who were admitted at once, so that the method of abortive treatment which we have adopted does not, like some of the drastic measures which have been advocated, prejudice the cure when it fails in its immediate object. Perhaps a longer period of probation would be a better index of success, but this would involve considerable administrative difficulties, and after all it is unlikely that live gonococci would remain a week in a fresh urethra without setting up acute inflammation.

Some Details of Technique of Local Treatment.

After the disease has passed the stage when abortive treatment is practicable there is some difference of opinion as to whether it would not be better to rely only on general measures rather than to supplement general measures by treatment applied to the urethra. I am bound to say that it would be a great advantage if we could dispense with local treatment, but I have treated parallel series of cases with and without local treatment, and there is no question that those on local treatment cleared up very much quicker. I would also refer you to a paper by Donald and Davidson, who treated two series of 200 cases each, one by local and general treatment and the other by general treatment only. Their experience agrees with my own and that of most genito-urinary surgeons, that in the present state of our knowledge we cannot profitably dispense with local treatment.

There are a few details connected with the local treatment which may be worth discussion, and I should like to deal first with

The Prevention of Secondary Infection.

If one takes the trouble to examine the secretion frequently throughout an attack of gonorrhœa, or, more certainly, if one takes cultures, it is depressing to find how quickly secondary organisms make their appearance, particularly staphylococci and diphtheroids, which are normal inhabitants of the preputial sac. No doubt these organisms are largely saprophytic, but I do not think they are as harmless in an inflamed urethra as they may be in the preputial sac. I have seen numbers of cases of chronic urethritis where diphtheroids and staphylococci seemed to be the only organisms present, and there were good grounds for believing that one or both were responsible for keeping up the irritation. Occasionally, too, one comes across a case where a prostatic abscess has formed years after an attack of gonorrhœa and the pus is packed with staphylococci, and we have good evidence that diphtheroids can set up a particularly intractable form of ulceration of the penis and inguinal region.

In dealing with large numbers of patients, as we have to do in the Army, I have found it particularly difficult to exclude this secondary infection. Circumstances work rather strongly against one's efforts. Those responsible

for the constructional details of irrigation rooms have tended to act on the principle that the arrangements for such a sloppy process as irrigation could most suitably be housed in a wash-house type of place, and once an irrigation room has been built it is pretty difficult to get it altered. Such surroundings must act on the patient's mind and tend to increase his normal carelessness over such details as disinfection of the glans prior to irrigation. Most patients are content to allow a little of the irrigating fluid to flow over the glans prior to insertion of the nozzle, but I have never been able to see the value of a preliminary sluicing with weak permanganate of potassium solution and have tried to institute a more effective system of preliminary disinfection. In the beginning of the war I provided spirit lotion with which to swab the glans thoroughly. Later perchloride or biniodide of mercury lotion was provided, but I am afraid that even in my own hospital there is a great amount of carelessness over this preliminary rite, and unless one, so to speak, makes a drill of it, it is apt not to be carried out. I have brought up the point because the great majority of gonorrhœa patients will have to be treated in public institutions where they will have to irrigate themselves, and unless they are drilled into a habit of preliminary disinfection secondary infection of the urethra is sure to be common. Also it is fairly certain that subsidiary irrigation centres will be established, and it would be well to insist on their internal arrangements approaching the operating theatre rather than the washhouse standard.

Nature and Strength of the Irrigating Solution.

The nature of the irrigating solution and its strength are matters over which there is much divergence of opinion. Before the war I myself experimented with many different compounds, and I have since had the privilege of seeing very many more tried by different medical officers, never having interfered with anyone who wished to try a new remedy, provided that he did not propose something which was obviously dangerous and that he undertook to proceed carefully at first. Amongst others I have seen filtered sea-water, hypertonic saline, eusol, chloramine, and almost the whole range of silver salts, but, almost without exception, medical officers have settled on either one of the flavine compounds or permanganate of potassium, with a weak solution of a silver compound for a variant. At Rochester Row we have tried acri-pro and homo-flavine in different strengths varying from 1/500 to 1/5000 and have supplemented it with an ointment kindly provided by Dr. Browning with a view to keeping up the antiseptic effect. The stronger solutions seem to have been too irritating and most medical officers who are using it now employ a strength of 1/5000, though Davis claims the best results from injection of 1/1000 acriflavine. Our results with the flavine compounds have been very similar to those we have obtained with permanganate of potassium, but we are inclined to think that the permanganate are rather better. Permanganate of potassium solution may be said to be almost the routine irrigating fluid in Army hospitals, not because there is any order about it, but because medical officers have themselves found it to be the most reliable application we have for average cases. The strength of the permanganate of potassium is a matter over which there are differences of opinion. Some prefer to commence with about 1/4000 and increase to as strong a concentration as 1/1000, while others commence with 1/8000 and do not exceed 1/4000 in the later stages.

Advocacy of Weak Solutions.

Personally, I believe in the weaker solutions at first, though I know that the stronger solutions may stop the purulent discharge quicker by their astringent effect. After all, the purulent discharge represents the effort of Nature to cast the gonococcus out of the deeper tissues and from the follicles and crypts which open on the mucosa, and in the acute stages of gonorrhœa one should do nothing which will interfere with drainage. My view is that stronger solutions of permanganate and all definitely astringent solutions when used in the acute stages of gonorrhœa do interfere with drainage, and by doing so promote the formation of peri-urethral infiltrates.

Some time ago, on the strength of Captain Thomson's discovery that gonococci are very soluble in alkali, I suggested a trial of alkaline irrigating fluids. I thought that they might prove more soothing to the mucosa, more destructive of gonococci, and, by their solvent effect, assist drainage.

At first a sufficient amount of sodium carbonate was added to the permanganate solution, immediately before use, to make a 0.75 per cent. solution of the alkali, but this was found to be too strong, and we reverted to a $\frac{1}{2}$ per cent. Dr. Stoker, at the Rochester Row Hospital, has adopted the alkaline irrigation as a routine. He finds that it is more soothing, and there is some evidence that it promotes drainage better in the comparative absence of peri-urethral infiltrates.

Anterior versus Anterior and Posterior Irrigation in Anterior Urethritis.

Genito-urinary surgeons are divided in opinion as to whether in purely anterior urethritis one should confine one's irrigation to the anterior urethra or, after washing the anterior urethra, allow the solution to enter and be ejected from the bladder. It is urged against irrigation into the bladder that the posterior urethra may become infected unnecessarily, and that such complications as epididymitis are much more likely to occur. I should like to advance some arguments in favour of irrigation into the bladder in all cases, whether purely anterior or not. First, it is well known that in a high proportion of cases the posterior urethra becomes infected without any local interference whatever, and posterior infection is not unknown under purely anterior treatment.

Also it is impossible to detect the moment when the infection is implanted on the posterior urethra. Yet it is granted by all that the surest method of preventing infection of the urethra is to wash away the infection as soon after its implantation as possible. I think that on these grounds alone, with the chance of the infection passing to the posterior urethra always present, one should keep it well washed from the first. Then it will be admitted that our object in irrigation is to wash away the irritating discharges and promote drainage from the deeper tissues, follicles and crypts opening on the urethra. I should like for a moment to consider which method is the more likely to effect this purpose. With anterior irrigation the urethra is distended as far as the compressor urethra, and, when the nozzle is removed, the irrigating fluid is forced out of the urethra merely by the collapsing walls of the urethra. It slops out, in fact, and its effect in removing secretion which may be blocking the mouths of crypts and follicles must be very slight. Then consider the effect when the sphincter is persuaded to open and the fluid allowed to enter the bladder. After some ounces have collected in the bladder the nozzle is removed and the patient forcibly ejects the fluid. I think it must be granted that the cleansing effect must be greater; the mere rush of fluid past the mouths of the follicles in this direction must tend mechanically to remove the plugs from them and assist their drainage.

Regarding the risk of epididymitis, there are so many causes of epididymitis that it would be difficult to prove that posterior irrigation was a prominent one. The general incidence of epididymitis in gonorrhœa has been estimated by various authors at anything from 10 to 25 per cent. The experience of military hospitals is that the highest percentage occurs before admission to hospital—i.e., for the most part before any local treatment has been applied. For instance, out of 9797 cases admitted to one hospital which received patients direct from the front 11.7 per cent. arrived with epididymitis, while out of 1000 admissions to my own hospital 14.4 per cent. were suffering from epididymitis on admission.

After admission to hospital the rate varies with different hospitals, and I strongly suspect it has more to do with the amount of work the patients have to do than any other factor. In the hospital which I have just mentioned, where fatigues at one time were very heavy and have since become moderate, the rate after admission of those cases which arrived with no epididymitis has been 6 per cent.; in another hospital where there is a football ground the rate is 8 per cent.; while at Rochester Row, where the patients lead a very quiet life from the point of view of physical exercise an analysis of 268 consecutive cases admitted last year without epididymitis showed that 4, or 1.4 per cent., developed epididymitis while under treatment, and the rate for 1000 cases of 1917 and 1918 has been 2.1 per cent. I admit that irrigation can cause epididymitis, but it is wrongly conducted irrigation, especially irrigation at too high a pressure, but in most cases one can usually find another cause in too hard work, too early prostatic massage, or too early instrumentation.

I believe, then, that the best instrument with which to irrigate the urethra is the bladder, provided that certain conditions are fulfilled. Thus, the anterior urethra should be washed first as well as it is possible to do so with an anterior irrigation and then the sphincter must be *persuaded* to open by a combination of trickery and pressure of irrigating fluid. But the less pressure the better, and with ordinary irrigating tubing and Janet nozzle I prefer the vessel to be 4 rather than 5 feet above the penis.

The Attack on the Gonococcus Through the Blood Stream.

I think that most surgeons who have treated gonorrhoea to any extent must have felt keenly the limitations of local treatment. Until the gonococcus has been cast out of the deeper tissues by natural agencies we have no means of attacking it by local applications. Too often Nature fails to complete her task and we are left with residua of infection which require careful individual treatment to eradicate. Many remedies have been devised to penetrate the mucosa and destroy the gonococcus, but none have yet succeeded, and everyone will admit that if a remedy could be found which, circulating in the blood stream, would directly or indirectly bring about the destruction of the gonococcus gonorrhoea would be a much more satisfactory disease to treat than it is at present. My colleagues and I have experimented with a large variety of compounds, but have so far not found any chemical agent which is a specific for gonorrhoea in the sense of bringing about destruction of gonococci. At one time a very large number of patients under my control were treated with intramuscular injections of mercurial compounds, especially succinimide of mercury, and at first it seemed as if a solution of the difficulty might be found in a mercurial compound. Very frequently the first injection of the mercurial compound was followed by an almost miraculous disappearance of the discharge, and very many cases seemed to clear up very rapidly indeed. On the other hand, relapses were much more frequent than under ordinary treatment and cases which did not clear up quickly seemed to drag on with a chronic gleet much longer than those treated by ordinary methods. Altogether, when the account of about 7000 cases was made up I found we had gained nothing. I should not have pursued this will-o'-the-wisp so long had it not been for the fact that of all the mercurial compounds which I tried the succinimide and camphorimide had the greatest effect and some makes of succinimide of mercury worked better than others, all of which led me to think that by patient research we might arrive at the right combination eventually. I am inclined now to think that the mercurial compounds reduced the discharge by interfering with the reactive power of the tissues, bludgeoning them so to speak. This would account for the slowness of recovery of those cases which failed to clear up at once, though I admit that it does not account for those cases which undoubtedly did clear up in marvellously quick time.

Vaccine Treatment.

Failing a drug or a chemical compound we are left with a more natural method of ousting the gonococcus—viz., increasing the anti-gonococcal power of the patient's tissues by vaccines. Treatment of gonorrhoea by vaccines has appealed to me since in the early days of my closer acquaintanceship with gonococcal infections I witnessed the almost miraculous effect of vaccines I had prepared on cases of gonococcal arthritis. I admit that, in metastatic complications of gonorrhoea, one can obtain excellent results from the injection of a variety of foreign substances into the body, as I shall mention in a moment, but I am convinced that these earlier results of vaccine treatment were not of the same type, and I can attribute them only to the specific effect of the vaccine in increasing the antibody content of the patient's blood. My experience of the vaccine treatment of gonococcal infections has been mixed. For the most part it has been an experience of long periods when one could legitimately doubt whether they did any good at all unless one compared parallel series of cases, vaccine and non-vaccine treated, with one another. These periods were, however, broken by brighter interludes which were repetitions of my earlier experiences when the injection of vaccine was undoubtedly producing excellent effects.

Summing up the whole matter, I concluded that the ordinary gonococcal vaccine is a poor antigen, but that occasionally one hits off a method or happens to use a strain

which results in a vaccine of good antigenic power. The conclusion is not original, since many workers, amongst whom I would mention Eyre, Nicolle and Blaizot, and McDonagh and Klein, have studied to improve the antigenic power of gonococcal vaccines, either by selection of strain or by method of preparation. The difficulty until recently has been to estimate the antigenic power of different vaccines by serological methods. McDonagh and Klein suggested that strains which were good antigens in the complement-fixation test should be selected for use as vaccines, and I think that in the complement-fixation test we have the best means of testing the antigenic power of a vaccine, though not quite in the manner suggested by McDonagh and Klein.

Inquiry in Regard to Gonococcal Vaccine.

When Captain Thomson joined as pathologist at Rochester Row in 1916 I suggested to him that gonococcal vaccine was a subject well worth study. Captain Thomson¹ began by devising a culture-medium on which gonococci grow profusely, and was thus able to command a large supply of gonococcal emulsion for experiment. A further step was made when the method of performing the complement-fixation test by preliminary fixation for many hours in the ice-chest proved to be a great improvement in regard to its delicacy. This improvement was suggested by the work of Mr. F. Griffith and Dr. W. M. Scott, of the Local Government Board Laboratory, who have extensively investigated preliminary cold fixation in the Wassermann test for syphilis. Then Captain Thomson found that the gonococcus is very soluble in alkali, and this has led to improvements in the method of preparing gonococcal vaccines which I hope that Captain Thomson and Captain Lees will have an opportunity of explaining to you. I will not trespass on their territory more than to sum up the matter thus. One may divide a gonococcus into two constituents, stroma and toxin. The toxin has very slight antigenic power in the quantities of it which can be administered with safety, while the stroma freed from its toxin can be administered in such large amounts that a far quicker antibody response is produced than by injection of the ordinary emulsion. Captain Thomson's vaccine is, therefore, gonococcus stroma minus gonotoxin, and is a far better vaccine than any I have yet seen administered. Fortunately for Captain Thomson's investigations he has had the advantage of collaborating with Captain Lees, whose careful observations of the clinical effects of the vaccine have proved of the greatest value.

Nature of Antigenic Effect.

It has been urged in some quarters that the good effects which have been noted in the complications of gonorrhoea as following on the injection of vaccines are not due to a specific antigenic effect but to that non-specific effect which has been termed protein shock, or, as Auld has termed it, pyrogenic therapy by the injection of foreign substances into the blood stream. There is no doubt that pyrogenic therapy is a most valuable aid to the treatment of metastatic gonococcal infections, especially arthritis, and we have a fairly large series of cases now in which the intravenous injection of 120 millions of ordinary antityphoid vaccine has produced most striking improvement. The dose is repeated, or increased to 150 millions, in about five days, and the improvement is proportional to the reaction produced. Very much the same effect is produced by the injection of intramine, but, on the whole, I think that the antityphoid vaccine produces the quicker results. At one time we had half an acute ward on the antityphoid injections and the other half on intramine. They ran one another very closely, and the effect was always proportional to the general reaction. I have not yet tried horse serum, but believe that a similar effect would be produced. I do not think that the good effects we have experienced from vaccines depend on the same principle as protein shock because the new gonococcal vaccine produces little or no general reaction and we have had no good results from intramine or antityphoid vaccine unless a general reaction was produced.

Discussion.

Captain D. THOMSON said that although about 90 per cent. of 200 clinicians who had written on vaccine-therapy in

¹ THE LANCET, 1918, II., 42.

gonorrhoea were in its favour very little experimental work had been done to explain the cause of their success. Using the amount of complement-deviating substances as an index, he had been able to show that antibodies could be evoked in the human by the use of gonococcal vaccine; the serological results obtained were illustrated diagrammatically. He had succeeded in detoxicating the vaccine, thus permitting the use of much larger dosage than had formerly been possible—e.g., 10,000 millions of cocci could be injected without producing more than a slight reaction. The detoxicated vaccines were very successful in inducing the formation of anti-substances. If the complement deviation could be raised to 10 or 12 positive, no cocci were obtainable from the infected source.

Clinical Evidence of Value of Detoxicated Vaccine.

Captain D. LEES, speaking from the clinical point of view, said that he had compared the therapeutic results in five series of cases, each series being specially treated. Those which cleared up first and spent the shortest time in hospital were treated by vaccines. The remaining series in order of therapeutic success were cases treated by mercury for three days and then by vaccines, cases treated by medicine and irrigation, cases treated by mercury alone, and, lastly, cases treated only by rest in bed, without local or general measures. The cases treated by vaccine were characterised by a greater moderation in symptoms, absence of complications, improvement in general condition and mental outlook, less time spent in hospital, and freedom from relapses. Certain groups of cases had been treated by detoxicated vaccines. One such consisted of 12 cases complicated by epididymitis in all of which cocci were found. 2500 million organisms were injected, the dose being subsequently worked up to 10,000 million. The acute cases cleared up very quickly, 1 in 6 days, 1 in 7, and 1 in 15; all have reported regularly since, and with one exception have kept free from infection. Another group was composed of 3 cases complicated by prostatic abscess. On an average the cocci disappeared in 45 days, the discharge in 59, the prostatic enlargement in 62, and the period in hospital was 69 days. Two cases with multiple arthritis and active gonorrhoea were similarly treated; the gonococci disappeared in 4 days, the discharge in 16.5 days, and the joints were normal in 56 days. The prostatic cases stood the treatment less well than the epididymitis cases and showed more focal reaction; in the joint cases there was no focal reaction and the general reaction was slight. A series of acute cases of five to seven days' duration was then treated, and the results were very striking. Comparative results of cases treated by no vaccine, by ordinary vaccine, and by detoxicated vaccine emphasised the value of the last as gauged by the complement deviation, the length of period preceding disappearance of organisms and discharge, and the duration of stay in hospital. With this treatment local reaction was practically absent, focal reaction slight for one day, and general reaction also slight except in one case. Disappearance of symptoms, cocci, and discharge was rapid. No complications developed except slight folliculitis in one case. The clinical results therefore tallied with the serological. He was convinced that the treatment is a valuable adjunct to that usually employed.

Views of Other Speakers.

Lieutenant-Colonel R. BOLAN had critically scrutinised the effect of the treatment by vaccines in a hospital of which he was in charge, and expressed himself as satisfied that the method was the best yet employed.

Captain D. WATSON was in almost complete agreement with Colonel Harrison. With him he favoured urethrovaginal lavage. He had given up all attempts of doing good by internal methods. His experience with vaccines had been varying, and he had seen cases where harm had been caused by their use. In 307 cases of acute gonorrhoea, the average stay in hospital had been 26.8 days. In 222 treated by acriflavine the period was reduced to 21 days. Twenty-six of these were accompanied by complications; in the remaining 196 the average stay was 19.8 days. Six per cent. relapsed. Complications arising in the 222 cases were epididymitis in 2 cases, subacute prostatitis in 2 cases, cystic abscess in 3 cases. The treatment must be continued for 10 or 12 days, although the discharge ceased after 3 or 4. The strength employed had been 1-4000 acriflavine with normal saline.

Captain EDWIN DAVIS, U.S.A., who had worked experimentally with acriflavine, considered that it is worthy of a more thorough trial, for it inhibits growth of gonococci in 1-300,000 dilution, does not lose its power in urine, shows a great tendency to penetrate tissues, and, moreover, is non-toxic and non-irritating.

Mr. CAMPBELL WILLIAMS spoke critically of many of the procedures adopted in the treatment of gonorrhoea, notably the giving of injections with the patient lying on his back, the use of mechanical apparatus for elevating the containing vessel, and the application of a band around the penis. He cited an instance where the disease had been prevented after infection. Relapse was frequently due to reinfection from small glands in the neighbourhood of the frenum, and treatment directed towards them would often avoid it.

Colonel HARRISON briefly replied.

ROYAL SOCIETY OF MEDICINE.

SECTION OF MEDICINE.

Pyrexial Symptoms of Malaria.

A MEETING of this section was held on Jan. 28th, Dr. A. F. VOELCKER (Major, R.A.M.C.T.) being in the chair.

Captain GORDON WARD read a paper entitled "Pyrexial Symptoms of Malaria." The object of the paper was to provide guidance as far as might be for those who might be called upon to report (1) as to whether a man showed signs of having recently had an attack of malaria; and (2) as to how far a man was disabled owing to chronic malaria, the existence of which in the case was not denied. It was anticipated that such questions would arise after the war in industrial spheres and before pensions boards. The class of case met with would be quite different from anything hitherto widely known in Great Britain and, to a large extent, very different from the class of case met with amongst inhabitants of a malarial country. The paper was based on observations made on over 1000 cases of soldiers under treatment in hospital. These had contracted the disease in various parts of the world, but were seen only after their return to France or England. Owing to the needs of military service the patients were taking quinine during the period of observation. It was believed that the picture of malaria seen in these circumstances was that which would be met with in civil life for some years to come.

Symptoms.

The following list of symptoms did not profess to be exhaustive, but comprised those most likely to be of value.

1. Pyrexial rigor. A typical malarial rigor with shaking and hot and sweating stages might occur with no rise of temperature. This would not be often met with, but a knowledge that it did occur might prevent mistakes.
2. Herpes labialis was common the day after an acute attack.
3. Headache. This was frontal as a rule, sometimes occipital, almost never vertical. Temporal and frontal headache together were often seen. The patient's statement might often be verified by detecting hyperalgesia at the margins of the area in which pain was felt.
4. Eye signs. Conjunctivitis, photophobia, and nystagmoid jerking were frequent in acute attacks. In chronic cases photophobia, pain behind the eyes, and rarely strabismus, were seen.
5. Pharyngitis and laryngitis both occurred in association with acute attacks, just as they did in influenza and many other fevers.
6. Jaundice. Some people seemed especially prone to jaundice after attacks of malaria. A slightly yellow colour was suspicious in chronic cases.
7. Perisplenitis. A friction rub (lasting three to five days) might be heard over the spleen in a few cases.
8. Pain in the side. This might be due to pleural adhesions. If so, it was felt most on deep inspiration, and a course of deep-breathing exercises would often dispel it. It might be due to splenic adhesions when more complaint was made when the patients stood for long or took much exercise. These two occurred in chronic cases, and both were often due to malaria, the former, of course, indirectly. Pain in the side might also depend on hyperalgesia of the skin or muscles. It was then at times bilateral. This was frequent in acute cases.
9. Tremor. A fine tremor of the tongue and hands, rarely of the lips, was common. It might persist in chronic cases, and was then often associated with chronic headache and depression.

10. Pigmentation. At times pigmentation was seen to increase with attacks and diminish between them; this was a good but rare sign.

11. Tachycardia was common when the patient first got out of bed, and might persist or only be elicited on exertion.

12. Hyperidrosis. This was not infrequent, although not often complained of. Occasionally it was so severe as to constitute a serious disability.

13. Splenomegaly. This was an uncertain sign in cases such as those under consideration. It occurred in indisputable form in severe attacks and when jaundice also was present.

14. Transient oedema. Local swellings of the nature of giant urticaria were sometimes seen on hands or legs; they lasted a few days only.

15. Raynaud's symptoms. "Dead fingers" and feet were often seen.

16. Weakness was often complained of, but was hard to assess. With the patient under observation it could be done by various tests, but must, as a rule, be a matter rather of opinion than demonstration.

17. Blood changes. The presence of the parasite was definite evidence. The presence of an increased number of "mononuclears" was of no value. A fall in hæmoglobin always needed explanation, but was not necessarily due to malaria. An increase of eosinophils was suggestive of malaria, as also was the presence of endothelial cells. The total number of white cells was of no particular value in diagnosis. The presence of abnormalities of the red cells, such as polychromasia, anisocytosis, and megalocytosis, was important and strongly suggestive of malaria.

In addition to the above, transient hemiplegia had been seen. Leg pains similar to those of trench fever were to be expected in a certain proportion of cases. Purpura was rare in the class of case dealt with. Urticaria and mastitis and a specific rash had been noted by some writers. Sudamina were not rare. Albuminuria would be of importance, but there was no opportunity of inquiring into the point.

Discussion.

Colonel ANDREW BALFOUR spoke of the relapses as probably indicating sporulation in internal organs. He agreed as to the occurrence of apyretic rigors, which usually merged later into more definite pyrexial relapses. It was questionable as to whether the rectal temperature would also have been found to be normal. If the thick film method of examination had been used the chances of finding parasites would have been increased. He raised the question of hepatic tenderness after malaria, a sequel which he thought not uncommon. It was difficult to state definitely that all the symptoms were malarial in origin.

Dr. F. S. LANGMEAD deprecated the common fault of ascribing all symptoms occurring in people coming from a malarial country, or even in malarial subjects, to the malaria itself. A more patient examination would sometimes show that a patient who was regarded as suffering from an unusual form of malaria was really the subject of an independent or secondary infection. Despite this warning, he agreed that malaria was almost as protean in its manifestations as Captain Ward had declared. He had had facilities for observing about 10,000 cases of malaria, and agreed as to the occasional occurrence of rigors without fever. Such rigors were frequently accompanied by malaise, headache, sweating, rapid pulse, mental depression, and even by vomiting. Cases had been seen of all degrees, ranging from those with rigors without alteration of temperature, through those with rigors where the temperature only attained the normal line, and those where the rigor was associated with a very slight pyrexia, up to those with characteristic pyrexial attacks. Pigmentation might be so severe as to resemble that of Addison's disease, and with this he associated also cases with temporary or persistent low blood pressure and small pulse, possibly ascribable to suprarenal defect. Defective action of this gland and also of the thyroid was suggested by the tachycardia, tremor, and exophthalmos which had been referred to and which certainly occurred. He had come to regard tachycardia in malaria as occurring in three clinical forms: (1) a transient form abating with or soon after an attack; (2) a more persistent form which subsided after several days or weeks; (3) a chronic and protracted form which possibly would remain permanent. It was difficult to say when the last two forms were indications that the malaria was merely in abeyance. Statistics as to the efficacy of various forms of treatment in preventing relapses were unreliable, as what constituted a relapse was often decided by rule of thumb and apyrexial attacks were not considered.

Dr. J. A. ARKWRIGHT spoke of the presence of urobilin in the urine as a valuable help in diagnosing malaria in the absence of a paroxysm.

Captain WARD briefly replied.

TUBERCULOSIS SOCIETY.

Practical Remarks on Tuberculosis in Relation to the Upper Air and Food Passages.

A MEETING of the Tuberculosis Society was held at the Royal Society of Medicine on Jan. 27th, under the presidency of Dr. HALLIDAY SUTHERLAND.

Dr. DUNDAS GRANT in a lecture on the above subject touched upon most of the conditions which tax the resources of the tuberculosis officer and the medical officers of sanatoria and hospitals. Many of the forms of treatment of tuberculosis of the larynx are only suitable for the specialist, but Dr. Dundas Grant gave an optimistic review of the results obtained by the simpler methods. Attention was called to rest to the larynx by silence and the voiceless whisper, much improvement occurring in the voice and condition of the vocal cords in a few weeks. Although a "useful" cough was to be permitted, many coughs by patients were useless and injurious. Much of this injury might be avoided by the voiceless cough practised without closure of the vocal cords. Continuous inhalation, advocated by Dr. Burney Yeo and Dr. David Lees, was referred to, but Dr. Dundas Grant considered its value chiefly due to relief of cough and not to any bactericidal effect. He recommended the following inhalant:—

Creasot. ... 3III.
Ol. pini sylvest., spir. chlorof. ... aa. Siss.
Ol. cinnamon., ol. citronell. ... aa. mv.

With menthol gr. v., gradually increased unless found irritating.

Nasal obstruction and nasal catarrh had a markedly detrimental effect upon laryngeal disease, and he said that these conditions should receive full attention. The use of a simple alkaline and antiseptic nasal lotion, employed with the aid of Grant's inspiratory nasal douche, of the following formula was often followed by very good results:—

Sod. biborat. ... gr. xvi.
Sod. chlorid., sod. salicylat. ... aa. gr. xlviii.
Glyc. pur. ... m. lxxii.
Aq. menthol. ... ad 3 vi.
A teaspoonful to the ounce of warm water.

In local conditions with great pain removal of portions of the epiglottis or the aryepiglottic fold had frequently to be performed, but in a great measure these procedures were obviated by the use of the galvano-cautery, the results in disease of the larynx, tongue, and nose being most gratifying. In this connexion inhalation of orthoform and anaesthesia by means of Leduc's powder inhaler, which the patient could learn to use by himself, was advocated and described. Dr. Dundas Grant said that the injection of alcohol into the superior laryngeal nerve to produce complete anaesthesia might with a little practice be accomplished with fair precision, affording great benefit. In concluding he mentioned the treatment of enlarged tonsils and adenoids, the remote effects of which were of such importance in the chest disease of the child.

SOCIÉTÉ DE BIOLOGIE, PARIS.

THE following is a summary of some of the papers read at the meeting of the society held on Jan. 25th:—

P. PORTIER.—Development of Larvæ on Sterile Food.

L'auteur a observé le développement complet des larves de *Tenebrio molitor* obtenues au moyen d'une nourriture stérilisée à haute température (130°). Les animaux dans ces conditions sont approvisionnés de symbiotes par un mécanisme spécial (cryptogames ou micro-organismes inclus dans leurs tissus) qui s'y développent et échappent à la carence.

MICHEL SIEDLECKI (Cracow).—Remarks on the Terrifying Attitude in Animals.

A propos de ce qu'on appelle "la position terrifiante" des animaux, 1° La position de bataille et celle qu'on appelle terrifiante ne sont pas les mêmes. 2° Très souvent la position terrifiante n'a pas de valeur pour la défense de l'animal. 3° La position terrifiante peut être provoquée non seulement par la présence de l'ennemi au voisinage de l'animal, mais aussi par différents autres agents, soit la fatigue, soit en général une irritation de tout l'organisme.

Dr. BONNEFON.—R-generation and Revivescence.

"Régénération" n'égale pas "reviviscence." Les éléments cellulaires morts sont remplacés par des cellules étrangères au greffon. Il y a donc régénération et non reviviscence. Quant à la trame connective du greffon qui sert de canevas à cette régénération, elle n'a pas à mourir, ni pas conséquent à survivre ou revivre puisque c'est un "coagulum inerte." Elle ne peut qu'être assimilée. Tous ces faits ont été établis et interprétés au cours des recherches d'avant guerre sur la greffe de la cornée.

L. LAUNOY —Antagonistic Action of Blood Serum against Bacterial Proteases.

Il résulte de ces recherches que pour des actions protéolytiques qualitativement égales, l'action du sérum sanguin est beaucoup plus faible sur les protéases microbiennes que sur la trypsine. D'où l'auteur conclut que l'interprétation qui fait du pouvoir antitryptique du sérum un phénomène banal, est incompatible avec les faits. D'autre part, l'auteur a obtenue par l'injection au lapin de protéases microbiennes l'apparition dans le sérum de propriétés inhibitrices très énergiques. Ces propriétés inhibitrices sont spécifiques pour la protéase injectée.

A. GRIGAUT, A. RANQUE, et Mme. POMMAY-MICHAUX.—Measurement of Bacterial Proteolysis.

Les différents microbes de la plaie de guerre, ensemencés sur le milieu à l'œuf, déterminent une protéolyse plus ou moins abondante dont la marche peut être suivie commodément au moyen du procédé de nœudisation décrit par les auteurs. Le dosage de l'azote non protéique notamment permet d'apprécier le taux de la protéolyse dans un milieu de culture déterminé et de mesurer l'activité protéolytique comparée des différentes espèces ou associations microbiennes.

F. CHEVREL, A. RANQUE, CH. SENEZ, et E. GRUAT.—Vaccine Therapy in Influenza.

Les injections intraveineuses de vaccin pneumo-streptococcique iodé parfaitement toléré, ont amené des décolorations brusques avec guérison dans de nombreux cas à complications pulmonaires graves. Dans les septicémies à streptocoques le vaccin n'a pas donné de résultats appréciables; par contre dans les septicémies à pneumocoques, la vaccinothérapie a donné des résultats excellents.

Reviews and Notices of Books.

Training and Rewards of the Physician. By RICHARD C. CABOT, M.D. London and Philadelphia: J. B. Lippincott Company. 1918. Pp. 153. 5s. net.

THE title of Dr. Richard Cabot's work is somewhat of a misnomer in that the book says not much about the studies and curriculum of a medical school. One admirable point in the work is the insistence with which Dr. Cabot urges the necessity for the physician being trained to understand his fellow men, seeing that patients are not merely "cases," but human beings with their own very real troubles and limitations. We must take exception to Dr. Cabot's statement on p. 45 that the physician,

"during his experience as a hospital interne tends to discard whatever he had known of human feelings, fears, delicacies, aspirations, and especially to ignore the differences of individuals and their need of individual treatment the young doctor at the end of his internship is often more nearly dehumanised than at any period in his life—before or after his hospital year."

We cannot think that this is strictly true; in our experience a year's work as a house surgeon or house physician in a big hospital will teach a man more about his fellow men and their needs than he would learn in the same time in almost any other work.

Dr. Cabot lays stress upon an important point which the ordinary public is in danger of forgetting and which many medical men do not realise, and that point is that nowadays the main work of the medical profession is devoted to doing away with illness—i.e., its own professional source of subsistence. While writing on this subject he quotes from a letter written by a patient suffering from tuberculosis who mentions that in June, 1903, he consulted a

"physician regarded as eminent in his profession and a man of long experience. I had then lost about ten pounds in weight. He examined me carefully, examined my sputa, found tubercle bacilli"

The patient continued to lose weight—namely, 8 lb. more in three weeks—and continued under the care of the physician until August, during which time "nothing was said to me in regard to outdoor living." He then read an article on open-air treatment in a popular magazine and, after consulting another physician, tried it together with rest, and recovered. Dr. Cabot quotes this incident as an example of the good which may be done by articles on medicine in the lay press. Such articles may, as in the above instance, do good, but they often do harm, and we must express surprise at a physician "regarded as eminent in his profession and a man of long experience," who, moreover, knew about tubercle bacilli, being either ignorant of, or

incredulous as to the benefits of, open-air treatment so recently as the year 1903. Public experience had made the value of open air public knowledge years before—in this connexion we may note that one of the earliest references in the lay press to the benefits of open-air treatment appeared in Lytton's "Strange Story," first published in 1862, while Reade used the same incident in "Foul Play" a few years later. A fine chapter in Dr. Cabot's book deals with the rewards of the physician. What these are we must leave to readers of the work to find out; we will merely quote Dr. Cabot's last sentence. Of the practice of medicine he says: "Its rewards, as I see them, are beyond those of any other profession."

United States X-Ray Manual. Authorised by the Surgeon-General of the Army and Prepared under the Direction of the Division of Roentgenology. New York: Paul B. Hoeber. 1918. Pp. 506. \$4.00.

THIS volume supersedes the small manual hurriedly prepared at the beginning of the war and is to serve as a guide to radiologists taking up military work, as well as a textbook for those without previous X ray experience. It is in consequence a very complete and concise treatise on the whole subject of X ray diagnosis, prepared with much care, containing numerous illustrations and diagrams which remove all ambiguity with an absence of superfluous verbiage. While, naturally, military practice predominates the line of demarcation between this and civil practice is really a very narrow one and the fundamental principles are the same. It is thus not too much to say that as a textbook for those who aim at proficiency in X ray diagnostic methods this would be hard to beat.

Every branch of the subject is treated as fully as the occasion demands, neither too much nor too little, and it is unnecessary to pick out any section for special comment. Great praise is due to those responsible for its production, not omitting the publisher, whose work is exactly suited to a book of this kind.

The Chemistry of Synthetic Drugs. By PERCY MAY, D.Sc. Lond., F.I.C. Second edition, revised and enlarged. London: Longmans, Green, and Co. 1918. Pp. 250. 10s. 6d.

THE progress that has been made in this country since the war in the production of synthetic drugs, formerly confined to Germany, adds considerably to the interest of this volume, now brought to a second, revised and enlarged edition. It is good to learn from an authority like Dr. May that though the manufacture of synthetic organic chemicals on a large scale presents many difficult problems, yet most of these have been successfully overcome by British chemists in so short a time; but he rightly points out that these successful efforts some day will come up against the vast and highly organised German organic chemical industry. That will present a problem which it will be the duty of our fiscal authorities to solve, but there is another point to be remembered. There can be little doubt that it would be an advantage if many of the synthetics were ruled out so far as regards therapeutics. As this book shows, it is not difficult to modify the structure of many compounds and to build up by the substitution of groups an extensive series of products which have a commercial impulse behind them rather than a pharmacological interest. Mainly addressed to the chemist who may not happen to know the exact chemical nature of these preparations, the book nevertheless affords attractive reading to medical men, who may thus trace the relationship of constitution (groupings) to therapeutic action.

Stoichiometry. By SYDNEY YOUNG, D.Sc., F.R.S. Second edition. With 90 figures in the text. London: Longmans, Green, and Co. 1918. Pp. 362. 12s. 6d.

THE not very elegant word "stoichiometry," the title of this book, implies a study of the laws governing chemical combination and their application to chemical calculation. This study involves a consideration of atomic values, according to latest determinations, of the functions related to these values, the properties of the different forms of matter as we know it, the solid, liquid, and gaseous states, the properties of all three states, their behaviour to one another, as in the solubility of gases and solids in liquids,

absorption, adsorption, and so forth. These subjects form the conspectus of the ground traversed by Professor Young, who has devoted himself to theoretical questions with the thoroughness and detail which have characterised his studies since the early days of his professional career. The practical importance of his work is revealed throughout the pages of the book, wherein the painstaking labour of investigators is revealed in sequence since the classic work of Stas (1831-1891), who, in spite of relatively simple facilities, obtained values so accurate that to this day they are retained as representing the truth as near as we can reach it by modern knowledge. It is of interest also to remember that Stas laid the foundations of the methods employed to the present day in the separation and identification of alkaloids. Professor Young has made a very important addition to a valuable series of text-books of physical chemistry, first issued under the editorship of the late Sir William Ramsay.

Introduction to Inorganic Chemistry. By ALEXANDER SMITH. Third edition, rewritten. London: G. Bell and Sons, Ltd. 1918. Pp. 925. 8s. 6d. net.

Professor Smith's teaching experience at Columbia University, where he is a professor of chemistry and administrative head of the department, has led him to try how best to open his subject to beginners, whether at university, college, or school. He makes the study of chemistry of interest from the start by coupling with the reading of this book a systematically arranged course of laboratory work in general chemistry, and the early chapters contain a discussion of a few typical experiments which bring before the student's consideration the manifold and broad questions with which chemistry deals, and the real purpose of its study. The theoretical portions are clearly written and well sustained by practical illustrations. This third edition is brought up to date, as evidenced in the chapters on dissociation, ionisation, and the modern methods of writing formulæ expressing reversible reactions.

There have been issued also two further books by the same author and publishers. One, *A Laboratory Outline of College Chemistry* (pp. 206, 3s. net), and the other, *Experimental Inorganic Chemistry* (pp. 170, 3s. 6d. net), which both form excellent guides to practical work in which particular attention is given to those details which, when instructions are followed, carry experiments to a successful issue and ensure accurate training.

Veterinary Post-mortem Technic. By WALTER CROCKER, B.S.A., V.M.D., Professor of Veterinary Pathology, University of Pennsylvania. With 142 illustrations. London and Philadelphia: J. B. Lippincott Company. Pp. 233. 16s. net.

As stated by the author in his preface, "the scientific study of pathology without proper post-mortem technic is impossible," and it is with a view to describing to the student the proper way to make a post-mortem examination that books of this kind are written. Veterinary literature has not been enriched by many books upon this subject, and Dr. Crocker's work should certainly be welcomed by many readers. It describes in full detail all the particulars necessary for exposing the important organs to be examined in cases of death from any special (or, indeed, any ordinary) disease, and the illustrative plates are excellently made, so that with these and the text no student can possibly go wrong.

The descriptions are a little American in style, and occasionally the expressions strike an Englishman as not being quite those he has been used to in student days, but they are very clearly put, and autopsies of all kinds of animals and birds are fully detailed. It is a book particularly useful in these days where even the ordinary practitioner is called upon to find certain hidden glands in order to obtain microscopic preparations from them and otherwise examine them. The clinical practitioner is apt to forget their exact locality, and as some are quite small he has difficulty in finding them. From such a book as this for reference he can obtain all the help and guidance he needs, and a most useful chapter is given on the average measurements and weights of organs. The book should be bought; if it goes too fully into small details the fault is on the right side. The author deserves every praise for a work which will be of real use to the veterinary profession.

JOURNALS.

British Journal of Children's Diseases. Vol. XV., October-December, 1918. Edited by J. D. ROLLESTON, M.D.—In their article on Ruptured Aortic Aneurysms in Childhood Dr. E. Bronson and Dr. G. A. Sutherland record a case of death due to the rupture of a fusiform aneurysm of the ascending arch of the thoracic aorta in a boy aged 5 years and 10 months. The aneurysm apparently followed a partial stenosis of the aorta between the insertion of the ductus arteriosus and the left subclavian artery. That this structure was a congenital anomaly was supported by the presence of a diaphragmatic hernia, subluxation of the joints, and defective cranial development. The writers classify aneurysms in childhood into (1) arterio-sclerotic; (2) traumatic; (3) embolic or septic; (4) false due to erosion from without; (5) due to congenital anomalies. The present case was an example of the last group. Two other instances on record of aneurysmal dilatation due to partial stenosis of the aorta are summarised, as well as five cases of aneurysms apparently due to congenital anomalies in the structure of the ductus arteriosus. In two of the latter rupture caused death. The writers have found in the literature seven reports of death following rupture of thoracic aortic aneurysms in children, one case of rupture of the aorta without aneurysm, and two cases of aneurysms of the abdominal aorta. A complete bibliography is appended.—In an article on the "Food Deficiency" or "Vitamine" Theory in its Application to Infantile Beri-beri, Major F. M. R. Walshe summarises the present state of our knowledge of beri-beri as follows. Beri-beri is dietary in origin in that it is associated with a physiologically inadequate diet. Yet the purely negative vitamine-starvation explanation of its pathogenesis, apart from the inadmissible nature of its contained assumption that a disease which clinico-pathologically is clearly an intoxication could be *solely and directly* caused by the mere *absence* of anything from the food, is inadequate in that it does not recognise the existence of the two factors essential to the production of the disease. These two factors are: (1) the absence of an unknown accessory factor or vitamine; and (2) the consumption of carbohydrates.—In a note on Abnormal Naughtiness in Normal Children, Dr. John Thomson points out that cases of this kind are essentially of the same nature as those of "moral imbecility" in children who are to some degree mentally defective. The proper treatment is as follows: (1) all severe corporal punishment must be stopped—it never does any good; (2) nobody must ever appear shocked, amused, or even surprised at anything the child does; (3) his misdeeds are never to be alluded to in his presence; and, lastly, he should be noticed and encouraged in every way when he is good, and altogether ignored when he is naughty.—Dr. Reginald C. Jewsbury records a case of Muscular Spasm in a Child, which Dr. F. Parkes Weber, in his remarks on the case, shows is the first example published in England of "Dystonia Musculorum Deformans" (Oppenheim) or "Progressive torsion spasm of childhood." The present case is exceptional in that hitherto the disease has been described only in Russian, Polish, and Galician Hebrew families. It runs a chronic progressive course with intermissions and even with periods of improvement, and may then come to a standstill, other portions of the nervous system remaining unaffected. It is characterised by a peculiar mixture of hypertonus and hypotonus of the affected muscles. The face and muscles of articulation are usually not affected except in late stages, when there is involvement of the muscles of the neck. Among the earliest symptoms is partial or total loss of function of one or more extremities due to faulty tonus innervation. Talipes tends to persist. The movements of the affected parts are spasmodic, but not truly athetotic. Psychical symptoms may occur, but the mental condition is generally normal.—The abstracts from current literature deal with diseases of the alimentary canal, surgery, orthopaedics, and ophthalmology.—The very full index contained in this issue should be an invaluable guide to current paediatric literature.

Journal of the East African and Uganda Natural History Society. No. 13, November, 1918. London: Longmans, Green, and Co. Price, to non-members, 5s. 4d.—Among the contents of this issue is an article by Mr. A. Blayney Percival on Game and Disease, in which the author develops his view that Nature has her own methods of preventing the spread of disease among wild animals, while at the same time she utilises disease as one method of ensuring the survival of the fit. Ngar naria he identifies with anthrax, and states that the Masai recognise the disease as one which man may contract. The Masai's treatment of the human patient is to promote perspiration by wrapping him in the freshly stripped warm hide of an animal, at the same time depriving him of all milk, giving him to drink only a decoction of a native root. In British East Africa, according to the author, both game and cattle have developed to some extent immunity against rinderpest, while the wart-hog has failed to do so.—In his notes on East African snakes Mr. A. Loveridge shows

that there is no easy criterion for distinguishing between poisonous and harmless species, variations in colour and shape of head being inconclusive.

La Medicina Ibero (Madrid, weekly) has now entered on its second year of publication, and may be congratulated on having won for itself a distinctive place among Spanish medical journals. Its abstracts of articles in Spanish, British, French, and American periodicals are a prominent feature and are excellently done. In the number before us—that for Dec. 28th last—Dr. Encinas abstracts the Spanish and Dr. Zapata the foreign journals. It is not easy to make abstracts interesting, but both writers have succeeded in doing so, thanks to an easy and lucid style and a sure judgment for salient points. Original articles are contributed by Dr. Villaverde and Dr. Alvarez. The former writes on "Spasm of the Orbicularis Palpebrarum and the Cervical Muscles," and discusses an interesting case in which bilateral orbicularis spasm, leading to almost complete closure of the eyelids, and causing the patient to throw his head back in order to see through the narrowed palpebral aperture, was followed, after a time, by a tonic contracture of the cervical muscles, fixing the head in the position at first adopted voluntarily. The case is of special interest in that the electrical reactions of the facial nerve were perfectly normal and that of the muscles supplied by the facial nerve, none but the two orbicularis muscles were affected in the slightest degree.—Dr. Alvarez writes on Milk as a Vehicle for Iodine. His article is a somewhat enthusiastic plea for a wider use of free iodine in therapeutics as against the mineral iodides, and for milk as the vehicle *par excellence* for its administration.

New Inventions.

NITROUS-OXIDE-OXYGEN-ETHER OUTFIT.

THE accompanying illustration depicts one of the patterns of the above machine. The main points are: (1) each cylinder is provided with a fine adjustment reducing valve (the valves are so constructed that they can be fitted to any ordinary English cylinder); (2) the principle of the "sight feed" has been adopted; (3) there is a small spirit lamp for

warming the reducing valve to the nitrous oxide cylinder; (4) a pressure gauge is attached to the oxygen cylinder; (5) a small rebreathing bag is attached, together with an ordinary 3-way stopcock and face-piece; (6) an ether bottle is connected up in the circuit; (7) the machine has been made in three sizes:—(a) The large size for work abroad. This machine, when fully charged, takes 4 cylinders of

200 gallons, 2 of 500 gallons, and 1 of 40 ft. capacity for oxygen. (b) The next size—the one depicted here—is meant for work in hospitals at home, and carries 4 cylinders of nitrous oxide of 200 gallons each, and a 20 ft. cylinder of oxygen. Types (a) and (b) are on wheels, and can easily be moved about. (c) The size for private practice takes 4 cylinders of 100 gallons, 2 of nitrous oxide, and 2 of oxygen. Cylinders of 25 or 50 gallons capacity can be used with this pattern. This type is so devised that the stand carrying the "sight feed" bottle and the ether bottle can easily be dismounted and securely stowed away between the cylinders. There is a covering lid and carrying handle.

These machines are economical in consumption of gas. 80 gallons of nitrous oxide and 20 gallons of oxygen are usually enough for one hour's continuous anaesthesia. I have now completed over 2000 personal administrations with this method, and am able to record over 1600 administrations by Captain Trewby and the residents at the 1st London General Hospital, making a total of over 3600 cases without any fatality. I desire to thank Captain Geoffrey Marshall, R.A.M.C., for many and valuable suggestions with regard to what was, or was not, required for use with this machine in France.

H. EDMUND G. BOYLE,

Captain, R.A.M.C. (T.); Anaesthetist to St. Bartholomew's Hospital.

A MODIFIED BUCHNER'S ANAEROBIC TUBE.

THE advantages claimed for this method are: (1) Simplicity. No special apparatus is required. (2) Tubes are shorter and less cumbersome than ordinary Buchner's tubes. (3) Economy of materials, which are readily obtained and are portable and compact. (4) Good anaerobiosis is secured. (5) Any medium can be used for cultivation.

The requirements are:—

1. A strong glass test-tube 6 inches long with an internal diameter of $7/8$ inch and a well-fitting rubber cork of 1 inch diameter.
2. The medium tube, containing liquid or sloped solid media of any kind, of a length of 5 inches, with an internal diameter of $7/16$ inch.
3. Four leaves of ordinary thick blotting-paper cut to a size of 4×3 inches.
4. Pyrogallie acid powder 1 g.
5. Caustic potash solution 16 c.cm. (Stock solution 109 g. caustic potash dissolved in 145 c.cm. water. Diluted 1 in 4.)

The conditions requisite for good absorption of oxygen in a vessel by alkaline pyrogallie acid solutions are: (1) large surface area of pyrogallie acid solution: (2) small air space containing the oxygen to be absorbed. These conditions are obtained in the manner shown in the accompanying diagram.

Method of use.—The dry pyrogallie acid powder (1 g.) is placed in the bottom of the outer tube. The four layers of blotting-paper, between the layers of which a little pyrogallie acid powder is placed, are wrapped round the medium tube, the long axis of the paper in the long axis of the tube. Medium tube and layers of paper are then slipped into the outer tube. (Outer tubes can be kept ready for use containing the blotting-paper layers and pyrogallie acid powder.) The caustic potash (16 c.cm.) poured into the outer tube, and the medium tube is rapidly slipped into the centre of the paper cylinder. As the medium tube is pushed in, the alkaline pyrogallie acid solution mounts as a thin layer between the outer tube and the medium tube to within a short distance of the top of the latter and drives out the air from the outer tube, thus reducing the amount of "dead space" from which oxygen must be absorbed. The rubber cork is pushed tightly into the mouth of the outer tube, the rim of which is sealed with paraffin wax. The layers of blotting-paper absorb a portion of the fluid and give to the absorbed pyrogallie acid solution a large surface area for the absorption of oxygen. The medium tube is suspended in the pyrogallie acid solution.

That good anaerobiosis is obtained is indicated by the fact that a tube containing 5 c.cm. of ordinary 1 per cent. glucose broth containing a solution of methylene blue or litmus is rendered quite colourless in 24–48 hours. Litmus milk tubes are also decolourised. The tube should, however, be left 2–3 hours to allow oxygen absorption to take place before incubation. Good surface growths of anaerobes with discrete colonies have been readily obtained on human serum glucose agar medium by this means.

H. J. B. FRY, M.D. Oxon.,
Captain, R.A.M.C. (T.F.).

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A clinical meeting will be held to-day (Friday, Feb. 7th), in the society's rooms, West London Hospital, when cases will be shown at 8 P.M.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 8, 1919.

The Medical Aspects of Flying.

ELSEWHERE in our columns we publish two papers which, although dealing primarily with the aeronautical side of medicine, are capable, in our opinion, of wider application. Dr. LOUIS STAMM describes a new form of reaction time apparatus which in his hands has proved of great value in assessing the mental qualities of flying pupils. It is true that with the coming of peace its application for the selection of officers appears to be somewhat curtailed, since the necessity for differentiating temperamentally the various types of pilots is no longer a matter of urgency. Indeed, for commercial purposes the good, steady, bombing pilot, or the unperturbed artillery observation officer, will possibly be looked upon with greater favour than the "star" of great stunting and fighting propensities. Nevertheless, in times of peace such an apparatus could undoubtedly be profitably used in the selection of airmen, and will probably prove of value in elucidating nervous conditions associated with "flying strain." Dr. STAMM attaches great importance to the more elaborate tests, and believes that these are of considerably greater value than the simple reflex times which can also be recorded. In view of the work done by Professor NEPPER and others on these simple reflexes, and the considerable importance attached by the French authorities to such tests, it will be interesting to see if the work of others confirms this opinion. It appears too soon to discard such simple tests altogether, and the matter must be investigated more fully. Apart from the examination of airmen or would-be candidates for aviation, it appears that the tests of Dr. STAMM are likely to be of considerable value in the examination of cases of shell shock, neurasthenia, hysteria, and other allied nervous conditions, and might profitably be worked in conjunction with "emotive" observations on the psycho-galvanic reflex.

The second paper, by Lieutenant-Colonel MARTIN FLACK, is in some ways of more immediate importance. With the coming of commercial aviation it will be a matter of supreme importance that only fit pilots are allowed to take passengers into the air. It will be particularly desirable that no pilot shall be liable to any breakdown which may endanger the lives of those entrusted to his care. Since all the tests described in the paper have had the normal standards set by observations upon successful flying officers, it appears to us that tests such as these should be employed in the examination of peace-time pilots. If properly carried out, the results of such simple tests will convey a fund of useful information to a medical officer called upon to examine airmen, and by a comparison

with results previously obtained an opinion will be formed as to the manner in which the subject is standing the strain of his occupation. The treatment of "flying stress" is essentially a preventive treatment, and careful examination along the lines suggested should be especially fruitful in preventing the onset of undue fatigue. It will give early indications of the need for rest on the part of the subject and prevent the bold and intrepid airman taking the air when, as not infrequently happens, he is not altogether in a fit condition to do so. Besides being of value from the point of view of the selection of the flying officer, we understand that the tests have proved of considerable value in assessing the effects upon the individual of what may be termed "minor crashes."

Apart, however, from their value in relation to flying, it appears to us that the tests will ultimately be found to be of wide application. With suitable modifications and appropriate standards they may be introduced into the various medical examinations in which the aim is to obtain an idea of the physical efficiency of the subject. In the past the physician has frequently concentrated his attention on the study of the abnormal, and has not assessed the normal at its true value. In a similar way the physiologist, while studying the more abstruse problems of the healthy body, has tended to overlook the value of such simple tests in estimating its efficiency. We believe that the simplicity of these tests will appeal to many and will serve to strengthen the bond of service which should exist, but too frequently does not, between physiology and medicine. Thus far in science there has been too much work in watertight compartments and insufficient liaison between the various branches. It is to be hoped that the time has now come when a close relationship will be maintained among the various scientific allies whose duty it is to make for the building up and preservation of the efficient state.

The Teaching of Medicine.

THERE are manifestations just now of a greater interest in medical education than has been known for a generation, and of a widespread conviction that reform is imperative. It is satisfactory to find that the monograph of Sir GEORGE NEWMAN, whose views must be of great practical value at this juncture, has stimulated thought and discussion on a complex and difficult question. In Scotland, as well as in England, the same interest is being evinced: the Edinburgh Pathological Club, for instance, has recently debated two papers by Mr. J. W. CRERAR and Dr. D. E. DICKSON on the Training of Medical Students for General Practice,¹ wherein the existing curriculums are closely scrutinised. The arguments in these two papers are not always directly applicable to English schools, but the defects of medical education in Edinburgh, as expounded at the Pathological Club meeting, are generally similar to those perceived by English educational authorities to be present south of the border. In some respects, however, changes advocated by English authorities have been inspired by a desire to bring English methods of teaching to a nearer approximation to Scottish practice.

Sir WILLIAM HALE WHITE is a consultant physician of unrivalled authority and experience as a teacher of

¹ Edinburgh Medical Journal, December, 1918, p. 350, et seq.

clinical medicine. His summary of the problem of post-graduate medical education in our columns on Jan. 4th includes principles which command universal assent, but when he comes to his own province of "primary" education in clinical medicine he becomes at once more detailed and more definite. He goes right to the heart of one of the difficulties of the medical reformer in London: the fact that the material rewards of moderately successful consulting practice are enormously greater than such emoluments as even the best and most hard-working of medical teachers can expect. This is a difficulty which is more acutely felt in London than elsewhere, in marked contrast to Edinburgh, which suffers less than many other schools from this disturbing factor. Sir WILLIAM HALE WHITE would forbid the chief of a medical clinic to engage in private practice, whether as physician, surgeon, or obstetrician; and if the salary of such a professor, as he would be called if any semblance of a chair were found for him, were large enough, and if such *imponderabilia* as professional status and public recognition were certain enough, there is a great deal of force in the arguments by which abstention from actual practice could be justified. But in present circumstances it is possible neither to offer sufficient salary nor to fulfil the other conditions named above, as far as London teachers are concerned, and, we should say, as far as the teachers are concerned in any part of England. Unless this state of affairs is fully faced any comprehensive scheme for reforming medical education is academic rather than practical. State aid is necessary; and with this the long-proposed principle of amalgamations among London medical schools can be combined. Sir WILLIAM HALE WHITE's plan would ensure the student receiving his teaching in clinical medicine from at least three teachers instead of from one only: a plan which, he believes, is good not for the student alone but for the teachers also. That must be rather a matter of surmise. The actual contact with the patient in the wards has always been the great point of London medical education, a contact which the inexhaustible clinical material of London has rendered peculiarly easy, and one which all our provincial schools try to provide for their students.

The equipment of the medical student for general medical practice presents at every centre of medical education one great problem—how best to correlate clinical teaching with laboratory work. Mr. CRERAR advocates that the general practitioner should be trained to do bacteriological work for himself; he dislikes the mere laboratory diagnosis of diphtheria. The tendency of the day is rather in the opposite direction of specialisation in clinical pathology, a tendency easily to be explained by the ever-increasing multiplicity and complexity of the work done in the laboratory. But it is absolutely necessary that the clinician should be associated with the pathologist and the bacteriologist in treatment. They study the patient from different angles of vision, and perspective is best attained when they exchange their points of view, while their intercourse should be free and frequent. It is in assessing the value of recent developments of laboratory diagnosis that general practitioners are often at sea; and many of them feel that of late years they have not had altogether the happiest of guidance in such questions from those leading teachers and consultants from whom they have the most right to expect it. Too

often methods of diagnosis and treatment have received the blessing of well-known teachers and clinicians, only to prove, after longer or shorter experience, to be fallacious. Many a practitioner has had to face this experience of feeling himself "let down" by those in authority, whose vigilance has been, to say the least, insufficient. And such failures not merely discourage the practitioner genuinely anxious to keep abreast with modern research; they directly encourage quackery amongst the less scrupulous, and rule-of-thumb methods amongst the lazy. Proper relations at all educational centres between the laboratory and the ward on the one hand, and proper relations between the clinical and the pathological aspect of disease in the practitioner's mind on the other hand, should alter all this, and it should not be impossible to secure these things.

Belgian Doctors' and Pharmacists' Relief Fund.

At the last meeting of the Executive Committee of this Fund a letter, a translation of which is reproduced in full on p. 235, was received by the Committee from Dr. V. PECHÈRE, the President of the Comité National de Secours et d'Alimentation (Aide et Protection aux Médecins et Pharmaciens Belges Sinistrés). The Comité National is the body sitting in Brussels to whom the dispensation of the contributions of the Funds in behalf of the suffering Belgian doctors and pharmacists in Belgium has been entrusted. The Belgian Doctors' and Pharmacists' Relief Fund has raised upwards of £25,000 during its life of a little over four years. The greater part of this money has been received directly from British doctors and pharmacists at home, in the Colonies, and in India, though during the closing stages of the war substantial grants have come from the American Red Cross, to the enormous benefit of the charges of the Fund. After the immediate wants of Belgian doctors and pharmacists and their families, arriving in this country as refugees, had been met by the Fund, the bulk of the money was duly distributed in monthly donations varying from £800 to £400 among Belgian doctors and pharmacists remaining in Belgium, the organisation of which Dr. PECHÈRE is the head undertaking the difficult and delicate task of distribution. Dr. PECHÈRE's committee has wisely husbanded the contributions sent to them, so that a certain amount of money should remain in hand for the succour and rehabilitation of Belgian doctors and pharmacists after the war; and it goes without saying that the extraordinarily generous suggestion of Dr. PECHÈRE, which will be found in his eloquent letter of gratitude—that this money should be returned to the Fund—has been disregarded by the Committee of the Fund. It was definitely stated in the original programme of those who organised the Fund that it would be impossible for British doctors and pharmacists to give too much money, because, when the immediate needs had been met, those of rehabilitation must remain and be very heavy. Many doctors and pharmacists in Belgium were materially ruined and would not be able to return to work without pecuniary grants. All readers of the medical and pharmaceutical journals who have kept the objects of the Fund in recollection will approve of the decision of the Committee of the Fund.

The Belgian Doctors' and Pharmacists' Relief Fund is closed as from Monday next, Feb. 10th, the small sum remaining in the hands of the honorary treasurer being probably sufficient to meet any remaining calls from Belgian refugees in this country. The Fund has disbursed the whole of the sum collected—over £25,000—save £90; and the cost of collection and distribution has been under £200, including the printing and postage of circulars and reports at war rates. The secretarial work and that of the treasurer have been done gratuitously, both by the officers named and by their assistants; a large proportion of the postage has been defrayed by THE LANCET; the auditors made their inspections of and reports on the books of the Fund for a nominal fee; and the Bank treated the Fund with special courtesy. These are the things that account for the economical administration of the Fund's resources.

Annotations.

"Ne quid nimis."

THE CONTROL OF TUBERCULOSIS IN FRANCE.

FRANCE, ahead of this country in so many departments of preventive medicine, has yet been tardy to take any concerted action in controlling the ravages of the tubercle bacillus; and with the history of the opposition to such measures in this country still vividly before the mind our Paris Correspondent's graphic story of the conflicting currents of medical opinion in Paris makes excellent reading. The great majority of doctors in France are, he says, hostile to the compulsory notification of tuberculosis. So they were in this country; but the notification has been confidential, has not broken that deep-seated instinct of professional secrecy which Paris holds as dear as London, the Frenchman as dear as the Briton, and notification has now, in consequence, no considerable body of opponents. Our Correspondent pictures the unhappy position of the notified patient when the agent of the local authority arrives with imposing apparatus to disinfect him and his dwelling, thus spreading terror among the indignant neighbourhood. Doubtless where tenement houses are the rule rather than the exception, the necessary measures of control and hygiene may attract undue attention, but in this country the tact of the tuberculosis nurse and sanitary inspector have already won the day. It is only exaggerated language that has ever described the tuberculous patient as a social pariah in this country or in France, and the tendency is but slightly marked in the stratum of society which provides the largest number as well as the highest percentage of tuberculous patients. The segregation of the advanced case of tuberculosis is of all measures the most practicable and the most urgent, and it should be possible to concentrate upon this without interfering unduly with the legitimate liberty of the subject. The Paris discussion is not without bearing on our own circumstances, where the return of the ex-Service and repatriated man constitutes a problem in tuberculosis control as urgent as any other problem facing us; and, unless properly handled, this problem is likely to cast a shadow on a generation or more.

SUGGESTED LUNACY REFORMS.

THE spirit of reconstruction, so much in the air, has recently been conspicuous in regard to our arrangements for those suffering from mental disorder. The results of the treatment of shell shock and other neuro-psychoses, brought into evidence by war conditions, on lines differing from conventional asylum treatment have of late attracted much public attention, and in January, 1918, the Medico-Psychological Association of Great Britain and Ireland appointed a special committee to consider the amendment of the existing lunacy laws. This committee, after lengthened consideration, reported last November in favour of certain radical changes as regards methods of dealing with cases of unconfirmed mental disease. Its recommendations included the establishment of "clinics" by local authorities for the treatment of nervous and mental diseases in their early stages, quite distinct as regards location and management from recognised institutions for the insane, and, where practicable, in the form of an annexe to a general hospital so as to be available for clinical teaching. The extension of the system of voluntary boarders to all classes of institutions for the insane was also recommended, as were facilities for the reception without certification of patients suffering from mental disease in its early stages into homes approved by the Board of Control, whether private or charitably founded, as well as into asylums, registered hospitals, and licensed houses, the only formality being an intimation to the Board of the fact of the patient's reception or removal. The committee, while not advocating, for the present, any complete revision of the Lunacy Acts, conclude their report by suggesting certain modifications of nomenclature as regards mental patients and the institutions for their treatment which would tend to eliminate the stigma attaching to such terms as "lunatic" and "asylum." It may be well to add that the report purports to deal exclusively with English lunacy legislation. The Board of Control in their fourth annual report, issued in August, 1918, express sympathetic views as regards the recognition and treatment in their earlier stages of indications of mental disorder. They proceed to recommend that the existing law should be amended so as to enable incipient or recent cases "to receive treatment in general or special hospitals, mental institutions, nursing homes, or elsewhere for limited periods, say, six months, without the necessity for certification under the Lunacy Acts, provided it has the supervision of the Board." They also approve of the establishment of "sections" (for both in- and out-patients) at general hospitals for the early diagnosis and treatment of incipient cases, including facilities for organised study and research where the hospital is attached to a medical school.

Having stated these expert professional views, we proceed to consider those forwarded to us of a "Conference of the Visiting Committees of the Asylums of England and Wales," which met at the Guildhall (City of London) on Oct. 29th last, having been convened by Mr. Thomas Field, chairman of the visiting committee of the Bucks County Asylum. This may be taken as mainly representative of the lay element in the administration of public asylums outside the county of London, with the addition of a small medical element, its committee including also five

delegates of the Medico-Psychological Association. The conference is reassembling at the Guildhall this week, and it may therefore suffice to say here that amongst the recommendations are that the words "pauper," "lunatic," "lunacy," and "asylum" should be deleted from the lunacy laws; that special mental hospitals for both in-patients and out-patients suffering from incipient or actual mental disease be established by local authorities, and that in such hospitals (not to be under the supervision of the Board of Control) certification should not be required until it may become necessary, in the opinion of the medical director of such hospital, to transfer the patient to an institution now known as an asylum. "Psychiatric clinics," it is suggested, should be established in connexion with every medical school, and proper facilities be provided therein for research and for teaching and training; and that medical officers appointed to institutions for the mentally afflicted should, within two years of their appointment, be required to hold a recognised diploma in psychiatry.

Reviewing these several sets of opinions, it would seem that there is a general consensus of feeling that the time is ripe for the relaxation of the legal fetters which have impeded the medical treatment of mental illness, especially in its incipient stage. In times past actual, as well as alleged, abuses have given rise to panic-begotten legislation, the restrictions imposed by which have tended to curtail the efforts of the conscientious practitioner for his patient's recovery. The restoration of greater freedom in dealing with those suffering from minor mental ailments is desirable alike in the interests of the patient and his doctor, and a reasonable discretion as to the most suitable surroundings for an incipient or harmless case of mental aberration ought not to be withheld. At the same time due precautions are necessary to guarantee the fitness and integrity of those undertaking the personal charge of mental cases, and some form of official approval—not to say supervision—seems indispensable for this purpose. The determination of the best form may appropriately be delegated to the prospective Ministry of Health. Though psychiatry must necessarily remain a specialty of the profession, its practitioners need to keep closely in touch with the advances of medical science, and it is to be hoped that the establishment of local clinics will tend to bring together in greater degree the family doctor and the specialist, at the same time affording opportunities to the general practitioner for a better insight into expert methods of mental treatment. It has been alleged that some medical officers of asylums, by reason of remoteness of their establishments from centres of ordinary medical activity, tend to comparative isolation from their confrères, and better opportunities of intercourse such as would result from the institution of psychiatric clinics would be beneficial to both classes of practitioners. We are glad to see that one of the proposals before the Guildhall Conference is to relieve medical superintendents of mental hospitals, as much as possible, of their administrative, clerical, and routine duties, so as to leave them more time for medical and scientific work. It must be remembered, however, that in comparison with similar establishments in America and on the continent the medical staff is proportionately low in British asylums, and much remains to be done in the equipment of laboratories for purposes of adequate scientific research.

THE MOBILISATION OF VENEREAL DISEASES.

THE appointment of an Inter-Departmental Committee last week by Dr. Addison to investigate the dangers of communicable diseases incident on demobilisation, and to devise concerted measures to meet these dangers may be taken as a recognition on the part of the Government of the extreme urgency of the situation in regard to venereal diseases. But while the need is so urgent responsible opinions are still sharply divergent in regard to the methods to be employed, and especially whether it is in the best interests of the community at large to popularise precautionary measures to be taken before infection has been incurred. Two important communications which we print this week should be read with close attention. At the Medical Society of London Colonel L. W. Harrison brought forward striking evidence of the value of the abortive treatment of gonorrhœa. We can reckon, he states from his abundant authority, with a fair amount of certainty on all the gonococci within the urethra being accessible to antiseptics on the first day of the developed disease. Promptitude of action is here of the first importance, and diligent propaganda are necessary to promote it. Sir Archdall Reid and Surgeon Commander P. H. Boyden, R.N., take the disinfection back to the very earliest post-contact stage. A swab of cotton-wool, a small quantity of a 1 per mille solution of potassium permanganate, used with sober care, have been effective in protecting 20,000 men—and an untold number of innocent women and children—against infection with the gonococcus. These are results which must be carefully weighed by any committee appointed to consider prevention of venereal diseases.

THE AMERICAN PUBLIC HEALTH ASSOCIATION AND INFLUENZA.

THE annual meeting of the American Public Health Association was held in Chicago under the presidency of Dr. Charles Hastings, medical officer of health for Toronto, from Dec. 9th to 12th, 1918, after having been postponed from October on account of the severity of the influenza epidemic. Many of the papers contributed dealt, as was to be expected, with influenza in its various phases, and an editorial committee was appointed to prepare and publish a bulletin formulating the facts and opinions brought out at the meeting. The main points in this influenza bulletin may be briefly stated thus. Influenza is believed to be caused by an organism of an infective nature, not yet exactly determined, which lowers the resistance of the body as a whole and of the respiratory organs in particular. This diminution of vital force leaves the system open to the invasion of other pathogenic organisms, of which the most important are the Pfeiffer bacillus and various strains of pneumococcus and streptococcus. Certain of these organisms are regarded by careful observers as the primary cause of the disease; but while one or more of them may be isolated from a particular case, the dominant variety of organism has been found to vary in different parts of the American Continent. As regards the use of prophylactic vaccine, if it is assumed that the cause of the epidemic is an unknown virus it seems impracticable to prevent the primary disease by vaccination with known organisms, whatever theoretical basis there may be for the use of vaccines directed against secondary infections, especially if the vaccine used includes
